THE ACTION OF SOLUTION OF AMMONIA UPON MIXTURES OF SILVER CHLORIDE AND BROMIDE.

BY ALFRED SENIER,

Lecturer on Chemistry in St. John's Training College, Battersea; late Demonstrator in the Laboratories of the Pharmaceutical Society.

This paper was written several years ago, since which time no important additional experiments have been made. The author sees no immediate prospect of the work receiving at his hands the further attention which it deserves, and meanwhile the results here described are of sufficient interest to justify their publication.

The action of solution of ammonia upon mixtures of silver chloride and iodide was investigated by Wallace and Lamont,* who proposed a method for their separation based upon the results obtained. The respective solubilities of silver chloride, bromide and iodide have been determined under various circumstances by different observers; but, so far as I have been able to ascertain, the action of solution of ammonia upon mixtures of silver chloride and bromide has not been examined. To obtain, if possible, an approximate method by which chlorides and bromides might be separated, or at all events to give precision to our knowledge of this subject, was the object in view when the experiments here detailed were undertaken.

The solution of ammonia used throughout had a specific gravity of ·959, corresponding to 10 per cent. of NH_3, the "liquor ammoniæ" in fact of the British Pharmacopœia. The silver salts were used in the moist, freshly precipitated state, quantities of dry sodium chloride and potassium bromide being employed to give the desired weight of silver salts. The alkaline salts were dissolved, either together or in some cases separately, in about 50 cubic centimetres of water, and were converted into silver salts by a slight excess of silver nitrate. The precipitate was allowed to subside and was washed with water twice by decantation. The ammonia solution was then added and the mixture thoroughly agitated and set aside to subside if anything remained undissolved.

In the first place the solubility of moist, freshly precipitated silver chloride and silver bromide in ammonia solution by themselves was determined. ·4076 gram of sodium chloride was converted into silver chloride (1 gram) and the ammonia solution added with brisk agitation until all was dissolved. Seventeen cubic centimetres of ammonia solution were employed, and hence the solubility may be stated with sufficient accuracy at 1 in 17. In the same manner the solubility of silver bromide was ascertained. ·1589 gram of potassium bromide converted into silver bromide (·25 gram) required for solution 62·5 cubic centimetres of ammonia solution. The solubility of silver bromide then may be taken to be 1 in 250. Having determined the solubility of the silver salts separately in ammonia solution, I then proceeded to study the action of ammonia solution on the silver salts mixed together, first with equal mixtures of silver salts and different quantities of ammonia, and secondly with the same amount of ammonia solution and varied proportions of the silver salts.

Action of Different Proportions of Ammonia Solution on equal Mixtures of Silver Chloride and Bromide.—An equal mixture of 1 gram each of silver chloride and bromide was prepared by dissolving equivalent quantities of sodium chloride and potassium bromide in water and converting the mixture into silver salts. These were washed and while still fresh were treated with 20 cubic centimetres of ammonia solution, or rather more than would be required to dissolve the silver chloride present if its solubility remained 1 in 17 as when treated with ammonia solution by itself. The result was an insoluble portion, which from its colour was presumedly silver bromide, and which when washed, dried and weighed in the usual manner gave 1·25 gram, or again 1·26 gram (see experiments (1) and (1*a*) in Table I.). Evidently the solubility of the chloride, assuming for the moment the soluble portion to be chloride, was modified by the presence of bromide, otherwise there should have remained insoluble in each of the two experiments only 1 gram at the most—the amount of silver bromide present. In the next four experiments, successively, larger proportions of ammonia solution were employed. They show that in order to dissolve 1 gram of chloride, when mixed with the same weight of bromide, 50 cubic centimetres of ammonia solution are required. In the presence of an equal weight of silver bromide the solubility of silver chloride, for the present amount, is then 1 in 50; but it must be observed that in experiment No. 1 the solubility is 1 in 27, and in No. 2 it is 1 in 33, while the last portion in experiment No. 5 dissolves 1 in about 400. Thus, while, as will be shown presently, too much importance must not be attached to these exact numbers, it is sufficiently evident that the solubility of the mixture decreases by degrees, of which the average solubility only of the silver chloride is 1 in 50. In order to determine whether the insoluble

4	1	1	80	·86	1·14	Insol. portion = bromide with a trace of chloride.
4*a*	1	1	80	·87	1·13	
5	1	1	100	·82	1·18	Insol. portion = bromide only.
6	1	1	50	·98	1·02	Silver salts precipitated separately.
6*a*	1	1	50	1·00	1·00	
7	1 Dissolved in 50 c.c. am. sol.	1		·98	1·02	Sol. AgCl in am. sol. 1 in 50 dissolves no AgBr.
7*a*	1	Enough to saturate 50 c.c. am. sol.		·12		Sol. AgBr. in am. sol. 1 in 250 dissolves AgCl, causing a precipitate of AgBr chiefly.

portions in these experiments contained really all the silver bromide, except, of course, in those cases in which the insoluble matter was less than 1 gram, it was not thought sufficiently promising to undertake any of the ordinary methods of quantitative separation, and, of course, in experiments Nos. 1–3, one would be certain to find some chloride qualitatively. I, therefore, tested the insoluble residues from experiments No. 4, No. 4*a* and No. 5, qualitatively by fusion with sodium carbonate and distillation with potassium dichromate and sulphuric acid. In the case of No. 4 and No. 4*a* much bromide with a trace only of chloride was found, while in the residue from experiment No. 5 no chloride could be detected. It is, therefore, at least approximately true that the chloride dissolves first, then the bromide. The next two experiments (6 and 6*a*) were conducted with silver salts precipitated separately and afterwards mixed together in order to prevent any possible production of double salts when, during the precipitation with silver nitrate, as would happen towards the middle of the operation, the two salts were being precipitated together. They gave insoluble portions weighing ·98 and 1·00 gram, thus showing, when compared with No. 3, that no appreciable difference occurs whether the silver salts are precipitated together or separately. Thus it is gratuitous to suppose either that a double salt or other compound is formed during the precipitation, or that the ammonia is prevented from acting upon the chloride by a physical coating of its particles by the less soluble bromide. All the experiments, so far, point conclusively to the fact that the solubility of silver chloride in ammonia solution is modified by the presence of silver bromide, so that when the latter is present in equal amount the chloride dissolves 1 in 50, and if sufficient ammonia is present the bromide dissolves 1 in 250, its solubility when separate. The next two experiments (7 and 7*a*) seem decidedly to confirm this view. A solution of chloride in ammonia 1 in 50, which is capable of dissolving nearly 2 grams more chloride, dissolves no bromide whatever; and again, a saturated solution of bromide in ammonia dissolves chloride 1 in 50, afterwards slowly precipitating a substance which in the experiment proved to be practically all bromide, and, moreover, a great part of the bromide previously in solution. These experiments show also that if, as is quite possible, new compounds are formed in these reactions, they are not produced by precipitation of the silver salts, but within narrow limits the ammonia solution may itself be the medium of such combination.

Action of Solution of Ammonia upon Unequal Mixtures of Silver Chloride and Bromide.—The following table exhibits the results of a series of experiments, first, silver chloride, and, secondly, when silver bromide is in excess:—

TABLE II.

Number of experiment.	Silver chloride. Gram.	Silver bromide. Gram.	Ammonia solution. Cubic centimetres.	Insoluble (experiment). Gram.	Insoluble (hypothesis). Gram.
8	·1	·9	25	·85	·82
9	·2	·8	25	·76	·74
10	·25	·75	50	·61	·60
11	·3	·7	25	·68	·66
12	·4	·6	25	·59	·58
13	·5	·5	25	·51	·50
14	·6	·4	25	·42	·39
15	·8	·2	25	·22	·18

The hypothetical numbers given in the table were calculated from formulæ depending upon the following hypothesis, a development of that already stated. When the proportion of silver bromide present is equal or in excess of the chloride, and when at least sufficient ammonia solution is present to dissolve the chloride 1 in 50, the chloride dissolves 1 in 50, any excess of ammonia solution dissolving the bromide also, 1 in 250, till saturated. Again, when silver chloride is in excess, and the quantity of ammonia solution is sufficient, the excess of chloride dissolves 1 in 17, the remainder 1 in 50, and the bromide 1 in 250, to the extent of the ammonia solution employed. It is clear from the table that the latter part of the hypothesis is inadequate, and an attempt was made to correct it with the view to a *quantitative analytical method for separation of chlorides and bromides.* But after a long series of experiments it was found to be practically useless. For example, the solubility of the silver salts in ammonia solution is altered by varying the degree of dilution—the solutions from the above experiments were rendered turbid by the addition of water—and under the circumstances of the case the proportion of water could not be kept uniform. Again, doubtless variable physical states of the precipitate which could not be avoided contributed to the results which were afterwards obtained, and which led to the abandonment of the hoped for quantitative analytical method. The exact limits of the solubility of mixtures of silver chloride and bromide in their bearing on *qualitative testing* I have investigated and incorporated in a separate paper.

To sum up, these experiments, taken as a whole, show:—that the solubility of silver chloride is not the same when mixed with silver bromide; that the solubility of moist freshly precipitated silver chloride in ammonia solution (10 per cent. NH_3) is 1 gram in 17 c.c., and of silver bromide is 1 gram in about 250 c.c.; that the solubility of the chloride in presence of bromide is much less, so that when the proportion of bromide is one half or more, it is, on the whole, 1 in 50; that silver bromide is insoluble in a solution of silver chloride in ammonia, 1 in 50; that silver chloride displaces silver bromide from its solution in ammonia, but that the unavoidable errors of experiment preclude the use of these facts in quantitative analytical separation of the two acid radicles. Finally, while the probability of the formation of double salts or other compounds as an explanation of these phenomena has not been disproved, still the prospect of getting at their composition, if such bodies exist, of making sure that they are not products of the processes employed, seems too remote and uncertain to encourage further investigation at present.

THE VALUE OF SILVER NITRATE AND AMMONIA AS A TEST FOR BROMIDES IN PRESENCE OF CHLORIDES.

BY ALFRED SENIER,

Lecturer on Chemistry in St. John's Training College, Battersea; late Demonstrator in the Laboratories of the Pharmaceutical Society.

It is well known that in cases where chlorides and bromides occur together the solvent action of ammonia upon their silver salts is of little value when applied in the usual manner of qualitative testing. The fact, however, that their silver salts differ so much in solubility in solution of ammonia, as seen in the preceding paper, induced me to find out by experiment exactly what value the method had when applied to definite proportions.

The results in the following table indicate that when mixtures of silver chloride and silver bromide are treated with definite proportions of ammonia solution, the presence of the bromide may be detected when its proportion is not less than about two per cent. of the silver salts or two and a half per cent. of the potassium salts. In these experiments enough sodium chloride and potassium bromide to give the required amount of silver salts was dissolved in a few cubic centimetres of water, the measured volume of ammonia solution (10 per cent. NH_3) was then added, and finally a few drops of solution of silver nitrate and the mixture agitated. No notice is taken of the by-products, sodium and potassium nitrate, etc., which are present.

No. of experiment.	Silver chloride. Grams.	Silver bromide. Grams.	Ammonia solution (10 p. c. NH_3) c.c.	Result.
1	·5	0	10	No precipitate.
2	·5	·025	10	Abundant precipitate.
3	·5	·02	10	Precipitate.
4	·5	·015	10	Precipitate.
5	·5	·01	10	Slight precipitate.
6	·5	·005	10	No precipitate.

These experiments led to the following method of testing. Weigh enough of the salt under examination to give approximately half a gram of silver salt. If it is a potassium salt, weigh 0·25 gram, or 0·2 gram if a sodium salt. Dissolve in about ten cubic centimetres of water and mix with ten cubic centimetres of ammonia solution (10 per cent. NH_3). To the mixture add a few drops of solution of silver nitrate, and agitate. A permanent precipitate indicates presence of bromides equal to at least two per cent. of the silver salts. Working in this way upon mixtures of known proportions I have obtained perfectly reliable results.

ABRUS PRECATORIUS AND ITS THERAPEUTIC USE IN OPHTHALMIC DISEASES.*

Abrus† *precatorius*, Willd, or Indian Liquorice‡ (Jamaica Wild Licorice; Liane de Réglisse, etc.) is a small woody twiner, with a long, woody, tortuous, branched root, ½ inch or more in diameter. It has slender, branched stems and a brown bark. Its leaves are alternate, shortly stalked, spreading, 2 to 6 inches long, abruptly pinnate, leaflets in about eight to fifteen closely-placed pairs, ½ to ¾ inch long, oblong, very blunt at both ends. Flowers are pale rose-tinted, small, in small clusters arranged on large tuberosities along the outer side of a stiff, curved rachis. The fruit is a pod, about 1½ inch long, broadly oblong, shortly beaked, somewhat compressed, two-valved, with imperfect septa between the seeds. Seeds four to six, globular ovoid, about ¼ inch long (of the size of a small pea); testa hard, bright and shining, brilliant scarlet, with a black patch at one end round the hilum; cotyledons plane-convex; no endosperm.

The plant is very common in all parts of India, where

* From *New Remedies*, June, 1883. A portion of the description is after Bentley and Trimen's 'Medicinal Plants,' No. 77, where there is a coloured figure of the plant.

For further information on *Abrus*, the reader is referred to 'Pharmacographia' (2nd ed.), p. 188; 'Bengal Dispensatory,' p. 297; Drury, 'Useful Plants of India,' p. 3; Waring in *Madras Quart. Med. Jour.*, 1860, p. 61; Moodeen Sheriff, 'Supplement to the Pharm. of India,' Madras, 1869, p. 17; 'Pharmacop. of India,' p. 74, 446; Dalzell and Gibson, 'Bombay Flora,' p. 76; Bolton, 'Medicinal Plants of Mauritius,' p. 43; Roxburgh, 'Flora Ind.,' iii., 257.

† *Abrus* is given by Prosper Alpinus (1592) as the name of the plant in Egypt, where the seeds were used for necklaces. Thëis derives it from ἁβρος, delicate.—*Bentley and Trimen.*

it is probably indigenous.* Bentley and Trimen say "that it is doubtlessly indigenous" in India and that it has probably been only introduced in other tropical countries where it is found, namely, South China, the Pacific Islands, tropical Africa, the West Indies, etc. But Dr. Moura Brazil has met with it all through the Brazilian province of Ceará, in the interior plateaus as well as along the sea coast; and, while a member of the Government Commission appointed to regulate the boundary between Brazil and Bolivia, he found it in the large and rich province of Matto-Grosso, between the two river courses of the La Plata and the Amazon, in the midst of virgin forests, where the hand of the husbandman had never penetrated. Yet he adds that it may have been carried there by birds. This appears not unlikely, since the seeds are so very conspicuous by their colour.

The seeds (also known as jumble beads, love peas, crab's eyes, prayer beads, pois d'Amérique, Paternoster-Erbsen, etc.) have been incorrectly stated by some writers to be very deleterious, two or three being, according to Herman, a fatal dose. They are, on the contrary, perfectly innocuous when eaten, and, although hard and indigestible, yet have been used as food in Egypt. In Hindu medical authors, they are recommended, when reduced to a paste, to be applied locally in sciatica, stiffness of the shoulder-joint, paralysis, and other nervous diseases. They have also been used in skin diseases and in fistula. When eaten they are reputed to prevent fecundity.

The root is employed in all hot climates (except China) for the same purposes as licorice. It was introduced into the Bengal Pharmacopœia of 1844 and into the Indian Pharmacopœia of 1868. Berzelius also noticed (in 1827) a sweet principle in the leaves.

The seeds have been used, according to Dr. Moura Brazil, for many years, in chronic granular conjunctivitis, in the Brazilian provinces of Ceará and Piauhy. In some portions of the former, the disease often assumes a very violent character, and the proportion of blind persons if very large. Whenever purulent ophthalmia is not carefully attended to, granulations are often formed, which are often followed by serious consequences. It is precisely in these chronic, granular cases, which have long resisted all other treatment, that the *Abrus* (or *jequirity*, as it is called in Brazil) is used with advantage. Yet, since the dose or the remedy is not always properly adjusted, and as the intensity of the artificial conjunctivitis produced by it is in proportion to the concentration of the solution, it may happen that an eye, otherwise capable of being saved, may be entirely ruined by a careless application.

Dr. Castro e Silva (of Ceará) published a small memoir, in 1867, on the use *jequirity*, in which he draws attention to the dangers connected with its use. He himself employed it in the proportion of 1 part in 700 parts of water, in form of lotion, applied several times a day.

In the interior of Ceará and Piauhy, where the remedy is much abused, cases have been reported in which, after two or three applications, there appeared a very intense inflammation of the eyelids and conjunctiva, extending over the whole face, the neck, the upper part of the thorax, and sometimes even affecting the sub-maxillary glands.

The remedy is usually prepared in the following manner:—The seeds are soaked during a few hours in boiling water, or during three or four days in cold water. When they are more or less softened, they are blanched, and the kernel reduced to a fine powder, which is macerated for twenty-four hours,* after which the liquid is filtered. The patient applies the liquid by bathing his eyes three times daily, in such a manner that it passes under the eyelids, or (if more concentrated) it may be dropped in the eye, during several consecutive days.

Immediately after the first application the patient's eyes begin to run, and he begins to feel a burning heat and a sort of heaviness of the eyelids. On the next day, the inflammation is so intense that he can no longer open his eyes, the skin of the lids becomes shining, of a violet colour, the conjunctival ecchymosis becomes more pronounced, accompanied with a more or less abundant muco-purulent discharge, and the patient complains of great pain.

Mr. Mello e Oliveira found that if the seeds are treated with boiling water slightly acidulated with hydrochloric acid, a bright, rose-coloured substance separates, which on the addition of some 45 per cent. alcohol, changes to red, a greyish-white substance of a gummy nature being deposited. The liquid, which has a red colour (after the addition of alcohol), when exposed for some time to diffused daylight, acquires, after a short time, a greenish colour persisting for several days. Ether separates from it an oil, and alcohol a gummy substance which is partly soluble in water and partly in alcohol.

After some hours, the portion soluble in alcohol changes its white colour to bluish-green. No alkaloidal substance could be detected in it because—as the author says—the appointments of the laboratory did not permit the execution of certain methods of extraction.† The seeds were subjected to processes employed for the detection of organic acids, and the liquid, after being filtered and concentrated *in vacuo*, had an acid reaction to litmus. This liquid was at first golden yellow, turning to dirty yellow when exposed to light and air. The acidity, which at first was feeble but distinct, after a while became very faint. While freshly prepared, it possessed the characteristic odour of the freshly powdered seeds, but whether the acid is of a volatile nature has not been ascertained.

Dr. Moura Brazil made experiments with all the substances isolated by Mr. Mello e Oliveira. The essential oil was found inert when applied to the conjunctiva; so also the grey and the white resinous principles. The green principle, the odour of which recalls that of the coffee-green seeds, was employed in quantities of 0·2 gram (ab. 3 grains) in 10 grams (ab. 160 min.) of water (see below).

Dr. Moura Brazil tried various preparations of jequirity upon rabbits, and thus ascertained the portion and quantity which produces the most severe inflammation. At first he used the seed and each one of its parts separately in fine powder and subjected to maceration, the cotyledons having been separated from the skin and likewise the embryonic radicle and gemmule. The results differed completely. With a solution of *jequirity* containing all these parts, and being of a strength of 1 in 20, the most intense inflammation was produced in the eyes of a rabbit. This inflammation yielded to no remedy and progressed to suppuration of the eye-ball, gangrene of the lids, and inflammation of the sub-maxillary glands. On using the cotyledons alone, without embryo (radicle and gemmule), in the same dose, the inflammation was much less intense. This is analogous to what has been observed in the case of the seeds of *Jatropha Curcas*, Linn., which, when employed with radicle and gemmule,

* In Sanskrit the plant (and its seed) is known by the name of *gunjá*, and various authorities give a large number of synonyms (over fifty) for it, which are partly taken from dialects or modern Indian languages. The seeds are also called *ratî* in Hindustani (=*raktiká*, Sanskrit), which is at the same time a name for a small weight (two and three-sixteenth grains) used by Hindu apothecaries and jewellers. The Burmese also use the seeds as weights. The plant (and its seed) is mentioned in Hindu medical works; compare U. Ch. Dutt, 'Hindu Materia Medica,' p. 151.—Ed. N. R.

* The original does not state in how much water, and adds "exposed to the night dew."—Ed. N. R.

† The analytical results here detailed are confusing, and certainly of no value whatever.—Ed. N. R.

produce violent emesis, while without them they produce scarcely any vomiting at all.

The dose has gradually been reduced to *four seeds* (without the testa and the radicle). In this way a mild inflammation is produced, permitting one application per day and sufficient to heal granulations in a few days. The cotyledons were reduced to fine powder, then macerated, the liquid filtered, and finally applied to the conjunctiva with a brush.

The results obtained with the green principle (see above, were so surprising that the author thinks the *jequirity* will form an important agent in ophthalmic therapeutics, inasmuch as granulations which had for years resisted all other treatment, were cured by *jequirity* in from twenty to thirty days.

This is of the greatest consequence for science and humanity, particularly for countries in the north of Europe, where ophthalmic inflammations are very common.

To repeat, the form in which Dr. Moura Brazil uses the *Abrus* is either a solution of 0·2 gram (or ab. 3 grains) of the "greenish extractive" (above mentioned) in 10 grams (160 min.) of water, or an infusion or cold macerate of the seeds (deprived of their testa, radicle and gemmule), made in the proportion of 0·5 grams (ab. 8 grains) to 10 grams (160 min.) of water.

The microscopic examination made by Dr. Silva e Chanjo of a recently prepared solution and of one which was two months old, as well as an examination of the false membranes it produces, has furnished remarkable results.

In all fresh infusions of *jequirity*, Dr. Silva found large polyhedric cells filled with a granular protoplasm. He considers them to be the cells of the seed itself, separated by the bruising and the maceration. Besides these cells there were found granulations, which, under a higher power, presented themselves as round, spherical, very brilliant bodies, capable of movement either around their axis or in a forward direction. With a lower power, they looked liked a fine powder. Dr. Silva considers them to be *gonidia*, or organs of non-sexual propagation.

On examining an infusion of older date, the aspect is different. Besides the powder—the *gonidia*—there are now noticed the true cells and tubes of a microscopic plant, with spores and mycelium. The spores are large, ovoid, sometimes solitary, or in groups of two, three, or more. The tubes either bear spores, or are bare and are branched. Between the spores and the tubes the above mentioned powder (the gonidia) is noticed. The older the infusion the better are these elements developed.

On the other hand, the microscopic examination of a false membrane (the conjunctival surface of the upper eye-lid, for instance), treated with or produced by *jequirity*, has shown this to be of a true diphtheritic character. It was found to consist of an agglomeration of particles of pus, held together by a fibrous substance and covered with gonidia exactly like those noticed in the infusion of *jequirity*. On macerating the membrane in distilled water for forty-eight hours, the elements previously described were noticed to be much more developed. (For further details of the microscopic examination we must refer to the original.)*

Dr. L. de Wecker, of Paris, who appears to have made similar observations on *jequirity* at about the same time as Dr. Moura Brazil, confirms the latter's statements, and sums up his observations as follows:

1. There is no doubt that an infusion of *jequirity* produces a purulent ophthalmia of a croupous nature, the intensity of which can be regulated by the strength and number of applications.

2. The cornea runs no risk during the development of the "jequiritic" ophthalmia.

* *Annales d'Oculistique*, Bruxelles, December, 1822.

3. The "jequiritic" ophthalmia cures granulations *rapidly*.

Dr. Wecker also states that he has vainly tried, by a careful study of Dr. Moura Brazil's memoir, to ascertain how the "active principle of a greenish colour" should be prepared. Two eminent chemists were also consulted, who declared, as might have been expected, that it was impossible to say exactly what was meant by that principle. Mr. Rabinet, at Dr. Wecker's request, prepared an extract of the seeds, and obtained a product of a deep green colour, which dissolved without difficulty in water, but the solution of it produced no action whatever upon the conjunctiva. Hence Dr. Wecker fell back upon the seeds, making an infusion in the usual manner.

Dr. Wecker also remarks that the preparation which has answered best in his hands, and which he is in the habit of using, is weaker than that used by Dr. Moura Brazil, being prepared from 10 grams (155 grains) of the decorticated and powdered seeds macerated for twenty-four hours in 500 grams (17 fluid ounces) of *cold* water and filtered.

From the April number of *La Farmacia Moderna* (Naples), we learn that Dr. G. Moyne, of Naples, has also used the infusion prepared as follows:—Thirty-two of the seeds were thoroughly triturated and pulverized; the powder was macerated for twenty-four hours in 500 grams of cold water, and then 500 grams of hot water added. After the infusion was cold, it was filtered and preserved in well-stopped, dark-coloured vials. When freshly prepared, the infusion is transparent and clear; after a few days, however, it becomes opalescent. At the same time it becomes less irritating. According to Dr. Moyne, it is useless to increase the amount of *jequirity*, since the effects will not be so satisfactory. The best proportion is 3·20 grams of the seeds (equally on an average thirty-two in number).

Finally, the Editor of the *Restaurador Farmaceutico*, of Barcelona, D. Juan Texidor, states in his journal (1883, 74) that Dr. D. José Maria Alcon has used the drug in thirty-nine cases, and found that effects were only produced with an infusion made from 4 grams of the seeds in 500 grams of boiling water. These discrepant statements are not calculated to create a great reliance upon the drug.

TEST FOR ARSENIC IN DOMESTIC FABRICS.*

REPORT OF A COMMITTEE APPOINTED BY THE NATIONAL HEALTH SOCIETY.

Chemical Report on the Test to be employed for the Detection of Arsenic.—It was found that, on the Continent, Acts or decrees exist, forbidding the sale of wall-papers, curtains, carpets and textile fabrics generally, if they contain arsenic. We had before us the decrees in force in Germany and Sweden. In the former, the prohibition of the sale of goods containing arsenic is absolute; in Sweden, a concession is made to manufacturers to this extent, that a paper or textile fabric shall be considered practically free from arsenic if an opaque black or brown arsenical mirror cannot be obtained from 68 square inches of paper, or 34 inches of a textile fabric, in a tube of 2 mm. (·078 inch) internal diameter. In the printed certificates issued by the Government, to be filled up by the chemist making the analysis, it is stated that the method known as the Von Babo and Fresenius test should be employed. The process is then minutely described, so as to insure uniformity of results. We ascertained from the Government analyst, in Stockholm, that the fact of the mirror being opaque is determined by observing whether or not a black line on a white ground could be seen through it. The fact that the presence of arsenic in domestic fabrics is injurious to health having been already ascertained by the Committee, the question for our consideration is simply that of the mode of testing. The first point for consideration is whether the

* From the *British Medical Journal*, June 23, 1883.

prohibition of arsenic must be absolute, extending to the most minute trace, or whether such minute quantities may be allowed as arise from accidental and unavoidable contamination. A very large proportion of fabrics of all kinds are found absolutely free from arsenic, no known test discovering the slightest trace; but, again, with regard to many fabrics, some traces are unavoidable in consequence of the very wide diffusion of small quantities of arsenic in natural products. The consideration consequently arises: first, as to what amount of arsenic it is requisite to allow as unavoidable and accidental contamination, in order that trade may not be hampered or interfered with to any undue extent; and next, whether that allowance may be permitted with due consideration to health. There are manufacturers of wall-papers (the principal articles in question) who have, on principle, abjured the use of all arsenical colours; the result of their work affords, therefore, an excellent guide for what may be demanded without unreasonable interference with the freedom of trade. An examination of a very large number of papers, supplied by these manufacturers, leads to the conclusion that an allowance of half a grain of arsenic per "piece of paper"—a piece being 12 yards in length and 21 inches wide—would be ample for accidental and unavoidable contamination; and this quantity, it is considered, would not be injurious to health. It is found that a suitable size for a sample to be tested is 16 square inches, to be cut from one part; or, if thought well, from several parts of the pattern, so as to include all the colours. The proposed limit of half a grain per piece gives ·001 grain per sample of 16 square inches. For ordinary uniform materials, a square of 4 inches by 4 inches may, therefore, be taken as the portion to be tested. We may remark, that the quantity of arsenic which we allow to pass by these tests is more than four times as much as would be permitted by the Swedish decree. We were at first of opinion that Reinsch's process, carefully conducted so as to insure uniformity of results, might be employed; but several wall-papers and many textile fabrics having been found which gave no arsenical reaction with Reinsch's test, however carefully conducted, but which, nevertheless, were subsequently proved to contain notable quantities of arsenic, this method was proved not to be an absolutely reliable test. A modification of Marsh's test is recommended as the most reliable, and as most suitable for a standard test to be inserted in an Act of Parliament. Detailed instructions are subjoined for both tests, in order that those who still desire to use Reinsch's method may get results comparable with the prescribed test by the modification of Marsh's process where arsenic is found.

Standard Test.

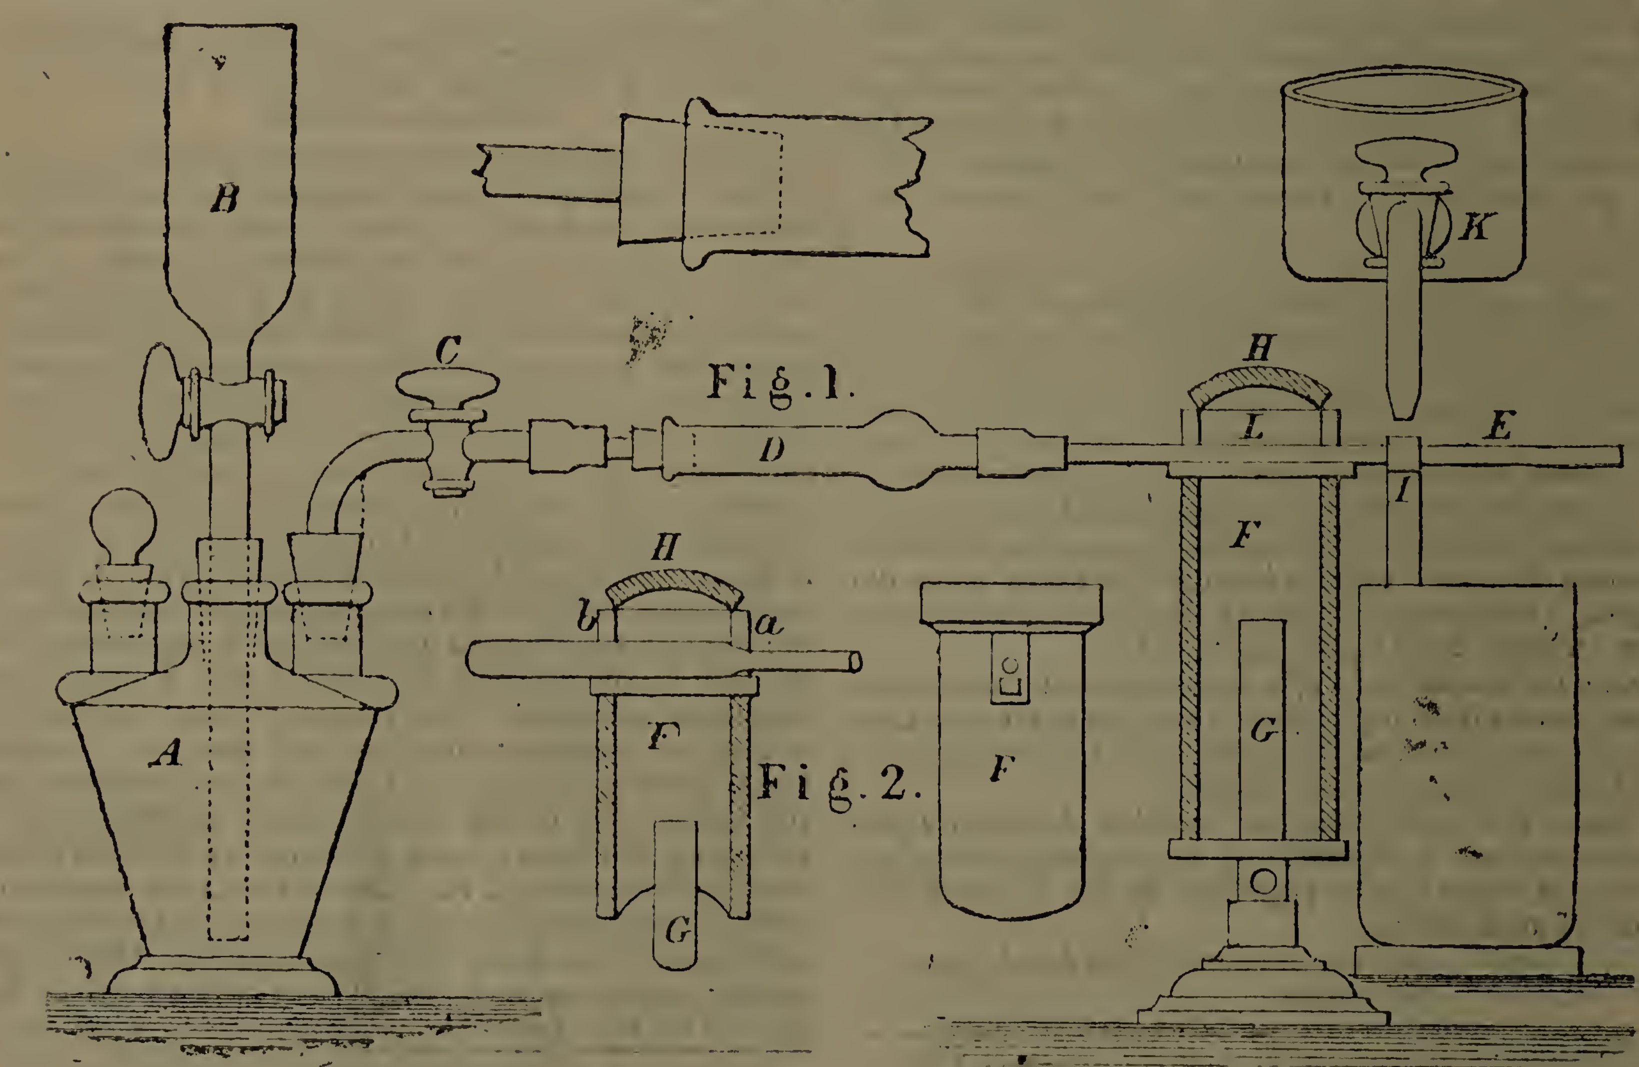
No paper should be passed as "non-arsenical," unless, when treated as hereafter described, it fails to yield a mirror in a tube $\frac{1}{8}$ inch internal diameter, sufficient to cut off at any point a black line on a white ground, technically known as thick rule (eight to pica).

Specimen Line.

In a three-necked bottle* of the form A, Fig. 1, of about 10 ounces capacity, place 200 grains of pure zinc.† To the centre neck, fit a tube funnel and stop-cock, B, and to one of the side necks a right-angled tube, and stop-cock, C. The third neck should be closed with a ground stopper. Connect with C a chloride of calcium tube, D, and with this a tube of hard glass, E, $\frac{1}{8}$-inch internal diameter, and about ·04 inch thick in the glass, if the paper or other material to be tested does not contain sulphur; but if, on being treated with hydrochloric acid, it yields sulphuretted hydrogen, the modification of this tube E, hereafter mentioned, must be adopted. Let this tube traverse a clay chimney, F, $1\frac{3}{4}$-inch diameter, and 6 inches high, in the top edges of which two slots have been filed to admit E, to the depth of 1 inch, and let E be supported on a thin bridge of the same material as the chimney, $\frac{1}{4}$-inch wide and $\frac{1}{8}$-inch thick slightly

* This form is recommended, as, in case of frothing, which frequently occurs, the froth is not driven into the tubes.

† Zinc sufficiently pure for this purpose can only be prepared by dissolving the purest commercial zinc in pure acid, so as to expel any arsenic as arsenuretted hydrogen; precipitating the zinc with pure carbonate of soda, washing the precipitate, and, when dry, reducing it. Messrs. Johnson and Matthey, of Hatton Garden, prepare zinc exactly in this manner, and supply it in bars, guaranteed free from arsenic. This zinc gives off hydrogen so freely that it is desirable to have the requisite quantity in one piece in the bottle so as not to expose too great a surface to the action of the acid.



notched, to rest on the sides of the chimney. This chimney surrounds a Bunsen's burner, *G*, of $\frac{1}{2}$ inch diameter. Over the top of the chimney, place an arched cover, *H*. Round *E*, at $\frac{3}{8}$-inch from the chimney,* roll a strip of thick blotting-paper or calico, $\frac{1}{4}$-inch wide, secured by a thread as at *I*. This should go at least twice round the tube, and hang down, as shown in Fig. 1; on to this, water is dropped from the bottle, *K*, at the rate of about 120 drops per minute (in very hot weather even faster). When the apparatus is thus arranged, pour through *B* 2 ounces of dilute hydrochloric acid, 1 part acid to 8 water. If any sample of zinc do not yield hydrogen with sufficient rapidity with this acid, slightly stronger must be employed. The hydrogen should be evolved with sufficient rapidity to keep alight at the end of the tube when fired. Close stop-cock on *B*, and let hydrogen escape through *C, D, E*, till all air is expelled. Now light *G*, and when *E* is quite red hot, close *C*, and introduce through the stoppered neck the 16 square inches of paper, cut into strips of 1 inch by 2 inches, and rolled up, so as to pass readily through the neck. This must include within the 16 square inches of paper portions of every part of the pattern, so that all the colours may be tested. Replace the stopper, open stop-cock *C*, and let the action continue for one hour. Now, extinguish *G*, and observe if a brown or black mirror be formed in *E*, between *I* and the chimney. If no mirror be formed, the paper is absolutely free from arsenic; if a mirror be formed, which, if the operation be properly conducted, will occupy about $\frac{3}{16}$ inch in the tube, lay *E* along the black line before spoken of, in front of and pointing towards a window, and observe, with one eye exactly over the tube, whether at any point the mirror be thick enough to obscure the line. Should this not be the case the paper may be passed as containing no more arsenic than may have got into it from unavoidable causes; should the line be at any point obscured it only remains to make sure that the mirror is arsenical. If, when sublimed with access of air, the mirror yield octahedral crystals it is arsenical. This operation is best performed as follows: The portion of the $\frac{1}{8}$-inch tube containing the mirror being cut out, take a thin hard glass tube, $\frac{1}{4}$-inch internal diameter and $1\frac{3}{8}$-inch long, sealed at one end, and lipped like a test tube at the other. Suspend this by dropping it through a hole cut in a piece of stout sheet-brass or copper, not less than four by two inches, so that the lip just supports the tube, and place the brass or copper plate on the ring of a retort stand. Heat the tube nearly to redness to expel the last trace of moisture; when cold insert the portion of the $\frac{1}{8}$-inch tube containing the mirror, and place, over the mouth of the tube and resting on it, a microscopic slide, warmed in a spirit lamp till all the moisture at first deposited has disappeared. Now heat the tube with the spirit-lamp, letting the flame play on the under side of the brass plate. In a few seconds a sublimate will appear on the slide. Watch this till it begins to shrink from the edges, and form a patch just the size of the bore of the tube. Remove the lamp, allow the slide to cool, and examine the sublimate with a magnifying power of not less than 220 diameters. If the sublimate is found to consist of octahedal crystals, it is arsenical. Such crystals are well shown on the photographs taken by Mr. J. H. Jennings, of 14, Beach Avenue, Nottingham.

If, on being treated with hydrochloric acid, a paper or other substance yield sulphuretted hydrogen, as before mentioned, or if, on being treated as above described, a yellow or whitish-yellow sublimate be found instead of a mirror the following modification must be adopted.

Substitute for the tube *E* a tube of $\frac{1}{4}$-inch diameter, having the $\frac{1}{8}$ tube sealed on to its end (Fig. 2); at *a*, the junction of the two, place a small plug of asbestos; fill the portion which traverses the chimney with a mixture of dry carbonate of soda and charcoal; and behind this, at *b*, place another plug of asbestos. The rest of the arrangement is the same as in Fig. 1. The red-hot carbonate of soda and charcoal retain any sulphur, etc., but permit the arsenic to pass. In this case, a little water is formed, and carried forward with the arsenic, which prevents the mirror having such well-defined limits as when it is perfectly dry; but a few experiments, made with known quantities of arsenic, will enable the operator to say with accuracy if a paper contain more than the permitted maximum of arsenic. It is remarkable how small a quantity of sulphur will completely mask a considerable amount of arsenic. Thus, sufficient ultramarine, mixed with a white pigment to give it a greyish tint, will quite prevent the formation of an arsenical mirror with four times the maximum quantity of arsenic permitted.

In the case of textile fabrics to be worn next the skin (as gloves, socks, or vests), experience has shown us that no trace of arsenic, however small, should be permitted. Curtains, carpets, etc., come under the same rule as wallpapers. In the case of carpets, it is better to remove the hempen backing on which they are frequently made up, and only to put the wool into the bottle. Some textile fabrics will not yield up their arsenic without previous maceration in strong acid. It is, therefore, desirable in all cases to submit the material to the action of pure hydrochloric acid, sufficient thoroughly to saturate it for a period of at least twelve hours previous to testing. When commencing to test, water should be added to dilute the acid. Textile fabrics should also be submitted to the action of zinc and acid for a longer time than papers; and it is safer, when the first portion of acid has nearly ceased to act, to add a quarter of an ounce strong acid through *B*, and let the action proceed for a second hour.

The only novelties that are claimed in this process are, first, the chimney of a non-conducting material, which confines the intense heat to $1\frac{3}{4}$ inches of the tube; and, secondly, the sharp condensing action of the water passing over the strip of blotting paper or calico. By these means, the arsenical mirror is concentrated, and not permitted to be carried off as arsenuretted hydrogen, as we have found to be the case when these precautions are not insisted on.

We recommend the Society to adopt and publish the proposed test, as a standard test according to which wall papers and other materials described in Appendix A, may be classed as "arsenical" or "non-arsenical," and their manufacture or importation be regulated accordingly.—H. C. Bartlett; Chas. Heisch; F. de Chaumont.

Appendix A.

Articles in which Arsenical Pigments, Dyes, or Mordants are used within the Knowledge of the Sub-Committee.—Paper, fancy and surface coloured; in sheets; for covering cardboard boxes; for labels of all kinds; for advertisement cards; for playing cards; for wrappers and cases for sweetmeats, cosaques, etc.; for the ornamentation of children's toys; for covering children's and other books; for lamp shades; paperhangings, for wall and other purposes; artificial leaves and flowers; wax ornaments for Christmas trees and other purposes; printed or woven fabrics intended for use as curtains or coverings for furniture; children's toys, particularly inflated indiarubber balls with dry colour inside, painted indiarubber dolls, stands and rockers of rocking-horses and the like, glass balls (hollow); distemper colour for decorative purposes; oil paint for the same; lithographic colour printing; decorated tin plates, including painted labels used by butchers and others to advertise the prices of provisions; japanned goods generally; Venetian and other blinds; American or leather cloth; printed table baizes; carpets; floorcloth; linoleum; book cloth and fancy bindings.

* The chimney is conveniently made by cutting the bottom off a Daniell's porous cell, and the cover by cutting a piece $1\frac{3}{4}$ inch off a similar cell and splitting it into three. The bridge also is best made of the same material.

Popular Test.

Although the Committee are of opinion that Marsh's test alone gives results of sufficient delicacy and accuracy to justify the taking of legal proceedings thereon, and have therefore adopted it in a modified form as the standard test to be appended to the proposed Bill, they are fully aware of the insuperable difficulties that stand in the way of its general employment in ordinary business transactions. It can only be practised by experts, and the fee which they would very properly require would, in the great majority of cases, deter the public from availing themselves of their assistance, although when a prosecution was contemplated it would be otherwise. Reinsch's test, though less delicate and, indeed, not absolutely free from the possibility of error, has been proved in hundreds of comparative trials to be, when carried out as they direct, accurate enough for all ordinary practical purposes, *i.e.*, for indicating the presence of a dangerous amount of arsenic, and when no graver consequences are involved than the acceptance or rejection of a particular paper.

Its advantages are that it could be undertaken by any professed chemist at a fee within the means of everyone, no small consideration when a large number of papers have to be examined; indeed, with the apparatus provided at the suggestion of the Society by Messrs. Griffin, of 22, Garrick Street, London, manufacturers, tradesmen, and intelligent householders might use it for themselves.

They thus hope that the end they have in view, the discouragement of the employment of arsenical colours, would be more speedily attained by the education of the public generally than by a few isolated cases of prosecution.

They, therefore, give directions for the performance of Reinsch's test.

Testing by Reinsch's Process.—The following is the mode in which this test should be used:—Sixteen square inches of the paper, either in one piece or several so as to include all parts of the pattern, to be cut up and put in a test-tube or flask with two ounces of dilute hydrochloric acid (4 distilled water to 1 of acid), and brought to the boiling point, a vertical condenser being used, if convenient; it is, however, not essential. A piece of copper foil, 1 inch by ½ inch, clean and bright, is now placed in the flask suspended by a thin platinum wire, by means of which it can be withdrawn, from time to time, for examination. After boiling gently for half an hour the copper must be rinsed repeatedly in water, and finally held under a tap, in a pair of forceps, to remove all traces of acid, etc. On no account is the copper to be touched with the fingers, as, even when wet, the grease of the finger interferes with the subsequent operations. No great stress can be laid on the amount of discoloration, as it varies very much, even with the same amount of arsenic, in the presence of other substances, such as sulphur, mercury, etc. The copper must then be treated as follows:—Dry it between two pieces of clean blotting-paper, and, holding it in the forceps, warm it very gently over a spirit-lamp; then, still holding it in the forceps, cut it into strips. Take a thin glass tube, ¼-inch internal diameter and 1⅝-inch long, sealed at one end and lipped like a test tube at the other. Suspend this by dropping it through a hole cut in a piece of stout sheet-brass or copper, not less than 4 by 1 inches, so that the lip just supports the tube, and place the brass or copper plate on the ring of a retort-stand. Heat the tube nearly to redness to expel the last trace of moisture; and, when cold, put the copper strips within, and place over it, resting on the mouth of the tube, a microscopic slide, warmed in a spirit-lamp till all the moisture at first deposited has disappeared. Now heat the tube with the spirit-lamp, letting the flame play on the under side of the brass plate. In a few seconds a sublimate will appear on the slide. Watch this until it begins to shrink from the edges and form a patch just the size of the bore of the tube. Remove the lamp, allow the slide to cool, and examine the sublimate with a magnifying power of 220 diameters. If the sublimate consist of octahedral crystals the discoloration of the copper is due to arsenic.

It is of course essential that the copper and hydrochloric acid used for this test be free from arsenic.

PHYSICAL CHARACTERS OF NITRO-GLYCERINE.*

BY MATTHEW HAY, M.D.

In view of the continued, and perhaps extended, use of nitro-glycerine in therapeutics, it may be desirable to add a few observations which I have made on its physical characters, more precise than those to be met with in previous publications.

Nitro-glycerine is perfectly colourless, and not of a clear yellow colour as is stated in most of the papers on the chemistry of this body. The colour is due to the imperfect removal of the acid, or to the use of soda which is commonly used for washing it, and which decomposes it with the production of a reddish-brown colour. It has no odour when cold, but has a sharp pungent odour when heated. Its taste is sweet, and not unlike that of glycerine, but is more pungent. As regards its solubility:—1 gram dissolves in about 800 cubic centimetres of water; with difficulty in 3 c.c. of absolute alcohol, easily in 4 c.c.; in 10·5 c.c. of rectified spirit (sp. gr. 0·846); in 1 c.c. of methylic alcohol (sp. gr. 0·814); in 4 c.c. of methylated spirit (sp. gr. 0·830); in 18 c.c. of amylic alcohol; in every proportion in ether; so also in chloroform, in glacial acetic acid, and in carbolic acid; in less than 1 c.c. of benzol; in 120 c.c. of carbon bisulphide; and to a very limited extent, if at all, in glycerine. Its solutions in water and alcohol I have kept for nearly four months without their exhibiting the slighest evidence of decomposition; and I have no reason for believing that they will not remain undecomposed for a much longer time.

NOTE ON GALANGAL.†

Galangal, which is the Rhizoma of *Alpina Galanga*, is brought over from Haian on the peninsula of Lei-chou, and from How Sui and Tam-chou on the west coast of this island. The article from the peninsula is far superior to that grown on Hainan. The former is cultivated on the slopes of hills about thirty miles distant from Haian, while the latter grows in a state bordering upon wildness, and is quite unsuited for the home market. The quality of galangal depends upon the age of the plant and the care which has been taken in drying the roots. Roots of ten years' growth are considered the best, but of late years, owing to a good demand for the article both at home and in the Hankow market, such qualities are rarely obtainable. The galangal now placed on the market is seldom of more than four or five years' growth, and prices have consequently declined. When taken out of the ground the root measures from 3 to 4 feet in length, and 2 to 3 inches in thickness; it is cut at once into small pieces and dried by exposure to the air. To give it a good appearance for the market, the Chinese use red earth for colouring purposes. Even the best roots lose considerably in weight in course of transport. A deduction of 10 per cent. for conveyance to Hong Kong, and of 20 per cent. for Europe is generally allowed on this account. In former years the crop was nearly all shipped in junks to Macao, but since the opening of Kiungchow the trade has been diverted to this port. The total annual production does not average more than 8000 piculs, the bulk of which goes to Europe, where, besides finding favour as a spice, it is used for medicinal and tanning purposes.

* Extract from a paper on the "Chemical Nature and Physiological Action of Nitro-Glycerine" in the *Practitioner* for June.

† From a Report by Mr. Acting Consul Jordan on the Trade of Kiungchow.

The Pharmaceutical Journal.

SATURDAY, JULY 7, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRITISH PHARMACEUTICAL CONFERENCE.

THE hospitable invitation issued this week to the members of the British Pharmaceutical Conference by the Local Committee at Southport will bring home to many pharmacists the welcome fact that sessions and seasons have an end, and that the time is once more approaching when they may hope to shake off the cares of business for a few days at least and join their brethren of the pestle and mortar in one of the most pleasant *réunions* of the year. Naturally there will be those who are looking with some curiosity for any information as to the nature of the local intentions in respect to the entertainment of the Conference, and therefore, although the programme is at present necessarily one of possibilities rather than certainties, we are glad to be able at so early a date to mention some arrangements that have been completed as well as others that are contemplated, purposing to revert to the subject when more positive statements can be made.

As is generally known, the meeting of the British Pharmaceutical Conference is to be held this year at Southport, in Lancashire, on Tuesday and Wednesday, the 18th and 19th of September. Unlike most of the places in which the Conference has met in recent years, Southport is neither an ancient city nor the seat of a manufacturing industry, neither does it boast of docks or arsenal. If the truth must be told it is somewhat of the butterfly order, and to find its nearest similitude amongst the entertainers of the Conference it would be necessary to turn back eleven years to the meeting in Brighton. Indeed, if Brighton be esteemed a London-super-Mare, Southport may be described as a place by the side of the Irish Sea where hard-headed north countrymen resort to find respite from the moil of money-making in the busy towns of Lancashire and Yorkshire. "It is essentially a health resort and seaside watering place;" but that in this respect it must be very attractive in its character is shown by its unusually rapid development, the number of inhabitants having increased from just over five thousand in the year 1851 to more than thirty-two thousand at the time of the last census in 1881. It may be added for the benefit of those who are weak in topography, that Southport is situated on the south shore at the mouth of the estuary of the Ribble, where a large expanse of sand stretches for some miles along the coast, forming a foreshore, which, it is needless to say, is not unknown to Her Majesty's Government. It is distant about eighteen miles from Liverpool, thirty-six miles from Manchester and sixteen miles from Preston, and is in connection with the railway systems of the London and North Western, Lancashire and Yorkshire and West Lancashire Railway Companies. Of course, like all watering places of any pretension now-a-day, it possesses an aquarium, a pier (built of iron and nearly a mile in length), a promenade and baths, besides which it boasts of the only real glaciarium in the world, a park, and winter and botanic gardens.

The business meetings of the Conference are to be held in the Assembly Rooms of the Prince of Wales Hotel, beginning and ending each day at the usual time; as usual, also, there is to be an interval for luncheon, which we understand will be provided by the Local Committee in one of the rooms of the Hotel. On Tuesday, at any time during the day, members will be able to visit the Winter Gardens and Aquarium, for which tickets will be provided. Immediately after the close of the meeting on this day those who feel disposed will be invited to adjourn to the Baths for a short time, where a special entertainment will be provided. On Wednesday, the Committee intend to invite the members to visit the Glaciarium, where some of them may feel disposed to disport themselves on skates; but it is hoped that it will be possible to provide other recreation as well, more in keeping with the scientific instincts of the company, and to make arrangements for a demonstration of the process followed in making the ice for the Glaciarium by GAMGEE'S method. On Thursday it is proposed that the company shall leave by an early train for St. Helen's, in order to visit one or more of the large manufactories in that town, but at present the negotiations are not sufficiently advanced to allow of any definite statement being made as to which. At any rate, it is intended that the company shall leave St. Helen's and return to Southport in time for a Garden Party, to which they will be invited by the Local Committee; this is to be held in the Botanical Gardens, which are to be specially reserved for the purpose on Thursday afternoon.

The "head-quarters" of the Conference during its visit to Southport will be at the Prince of Wales Hotel, which is pleasantly situated, and in which the Local Committee has secured a number of beds; we are glad to learn, further, that it has been stipulated that the ordinary tariff shall be adhered to. We hope, therefore, that under these circumstances, intending visitors who may wish to have accommodation secured for them will communicate their wishes at the earliest possible date to the Local Secretary of the Conference, Mr. WILLIAM ASHTON, 77, Lord Street, Southport

CINCHONA CULTIVATION IN CEYLON.

The report on the Royal Botanic Gardens in Ceylon for the year 1882, a copy of which we have received through the courtesy of the Director, Dr. Trimen, contains much interesting information respecting the cultivation of cinchona, which has now undergone such an enormous development that the bark has become the foremost product of the island. Some idea of the rate of increase may be gathered from the fact that during the year ending September, 1882, the exports of bark from Ceylon amounted to 3,099,895 lbs., or considerably more than double the quantity exported in the previous year. A large proportion of this was, however, unfortunately, of inferior quality, and Dr. Trimen thinks that at present there is little danger of an over-production of bark of the best quality in the island. Indeed, it is rather surprising to find that, notwithstanding the advice put forward time after time by Mr. J. E. Howard, it is the *Cinchona succirubra* which is rapidly displacing the coffee plant, though this is perhaps explained by the fact that this species is more easily cultivated. Dr. Trimen appears to think that the most promising future for the large yield of "succirubra" bark lies in its possible utilization for the manufacture of a cheap febrifuge such as is now made in India. On the other hand, there seems to be some evidence in favour of the assertion that the bark of the "succirubra" plant improves with increased age. Some fine trees are mentioned, about twenty years old, one of which girthed 37 inches near the ground and 25 inches at a height of 5 feet, and yielded 25 lbs. of dry bark. A sample of this bark, analysed by Mr. Howard, gave 6·8 per cent. of total alkaloids, 2·06 per cent. of which was quinine (equal to 2·75 per cent. of quinine sulphate) and 3·47 per cent. of cinchonidine.

The method of harvesting the bark introduced by Mr. Moens, which consists in shaving off the rich outer portions down to a plane as near the cambium zone as possible without touching it, proves to be so simple, expeditious and cheap, as well as convenient for drying, packing, and bailing for shipment, that it is now generally adopted, and it is probable that soon only renewed bark will be sent into the market from Ceylon. The trees do not appear to suffer much if the operation be carefully performed. The scraped surface is usually covered with "mana" grass (*Andropogon Martini*, Thw.), under which new bark is rapidly formed, the proportion of quinine being much increased in the renewed tissues. It appears, however, that there is a disposition to carry this process to excess, by operating at too short intervals and on immature plants. Experiments are greatly needed to determine several points in connection with this subject, such as the ratio of the increase of alkaloid in renewed bark to the age of the tree, and the length of the interval that should be allowed to elapse between successive shavings.

Among cinchona plants that are specially mentioned as having been received is a kind, from Kew, said to yield "hard Carthagena" bark, which is thought to be an undescribed variety or species occupying an intermediate position between *C. cordifolia* and *C. Calisaya*, with points of resemblance to *C. purpurea*. Some seed of the plant yielding "cuprea" bark has also been received from Bogota, but only one seedling survived at the date of closing the report.

We also learn from the report that an attempt is being made in the Botanic Gardens at Hakgala to cultivate some of the plants used in medical practice which are at present imported. Fair success has already been attained with the jalap plant, and among other medicinal plants that promise well are both the official species of rhubarb, belladonna, hyoscyamus, digitalis, and camomile. After a partial failure with taraxacum, which is largely used in the island, more than a quarter of a million plants were established and growing well at the end of last year.

In order to avoid misunderstanding, it may be as well to mention that the Medical Act (1858) Amendment Bill, which was read a third time and passed in the House of Commons, on Thursday, is not the Bill dealing with the general subject of medical regulations into which the Council is desirous of introducing an amendment, but a small Bill having for its object to vest in the Royal University of Ireland the right of sending a representative to the Medical Council, formerly possessed under the existing Act by the dissolved Queen's University, Ireland. The larger "Medical Acts Amendment Bill" has made no progress during the week and is now set down for second reading on Monday next.

* * *

It will be seen from the official notice on the front page that the examination for the Pereira and other medals and gifts of books, known as the Council Prizes, is to be held in London and Edinburgh on the 26th inst., and that persons desiring to compete must give notice of their wish to the Registrar on or before Saturday, the 21st inst. Any person who has passed the Major examination during the present session, and who was an Associate of the Pharmaceutical Society at the time of passing, is entitled to compete.

* * *

The excitement caused by the discovery that sophisticated quinine had been supplied for use in the Paris hospitals has now had its legitimate sequence in the arraignment of the offender before one of the correctional police courts in Paris on the two charges of adulterating a certain medicinal substance for the purpose of sale and for selling it after adulteration. We learn from the *Gazette des Tribunaux* that the right of supplying quinine sulphate for use in the Paris hospitals during 1882 was held by a person named Pressac, who proved, however, to be only a agent for a "druggist" named Lacombe. Suspicion having been excited as to the quality of the quinine sulphate supplied, an investigation was made, which showed that up to October the quality had been satisfactory, but that after that time it had not been so. One case received at the end of October is said to have contained a mixture of quinine sulphate and cinchonidine; another received in November contained a superficial layer of quinine, about 5 or 6 inches thick, the underlying portion being a mixture of alkaloids; whilst a third, received in November and not opened prior to the investigation, also contained only a superficial layer of quinine sulphate. The explanation offered by M. Lacombe was that he was an agent of the Lombardy Chemical Manufactory at Milan and that up to October he had supplied that brand of quinine, but that then having to dispose of two cases bearing another brand (Taillandier), and these having been different in size and form, in order not to raise any objection he decided to mix two boxes each of the "Milan" and "Taillandier" brands and fill the whole into Milan boxes. Whilst doing this he noticed that the appearance of the Taillandier quinine was very fine and gave orders that some of it should be reserved to spread over the Milan quinine; but the person entrusted with this work, deceived by the similarity of the Italian labels, used two cases of Milan "solfato di conchinino" as the substratum instead of "solfato di chinino." The defence was ingenious, but failed to satisfy the Court, for the sufficient reason, among others, that the substituted alkaloid was not conchinine (quinidine) at all, but the lower-priced cinchonidine. Lacombe was therefore sentenced to one year's imprisonment and to pay a fine of fifty francs. Moreover, as the fraud has been the occasion of a great deal of misrepresentation in respect to the Lombardy Company, it was ordered that a copy of the judgment should be affixed to the door of Lacombe's warehouse and retained there during twenty-four hours, and that it should also be advertised at his expense in twelve Paris journals, including the principal medical and pharmaceutical ones. Probably the *fons et origo* of the fraud is to be found in the existence of a contract to supply quinine sulphate for 374 francs per kilogram at a time when the market price of the salt was 400 francs per kilogram.

* * *

The Pharmacy Act of New Zealand, passed in 1880, appears to have been a somewhat crude specimen of legislation, it having already been found to be defective in several points, so that an effort is now being made by the Pharmacy Board to effect its amendment. In the first place there appears to have been no provision made for carrying out the election of Pharmacy Boards after the first, which goes out of office next year. Then all regulations made by the Board have to be approved and confirmed by a general special meeting of pharmaceutical chemists under the Act, which practically places the control in the hands of a few who are able to attend, as no provision is made for the reception of voting papers from the absent, an inconvenience which apparently it is proposed to meet by repealing the words requiring such approval and confirmation. Another proposed modification of the Act is in the same direction as an amendment now being sought of the British Pharmacy Act, namely to require that managers of branch shops shall be registered men. It has also been found that the simple prohibition of the assumption of the title of "pharmaceutical chemist" leaves room for a large amount of evasion, and it is, therefore, proposed to make it an offence for any unregistered person to keep an open shop for the compounding and dispensing of the prescriptions of legally qualified medical practitioners. Dealing in poisons in New Zealand is at present regulated under a Sale of Poisons Act, according to which any person, examined or unexamined, may sell poisons in the colony, if he is only registered and adopts certain precautions; but even these mild provisions are continually ignored, the police denying that it is their duty to see to their enforcement. It is, therefore, proposed to entrust the Pharmacy Board with the supervision of the sale of poisons, and impose a small licence fee upon registered sellers to cover the expenses. We understand that these propositions have been almost unanimously endorsed by the pharmaceutical chemists of the colony.

* * *

In December an International Exhibition is to be opened at Nice, one of the sections of which is to be devoted to sanitary and medical objects. The great interest which any movement likely to promote the sanitary improvement of the Riviera presents to the large number of British subjects who visit this district yearly has led to the issue of a circular, signed by a number of eminent medical men and others, asking that the active co-operation of British engineers, architects, manufacturers of sanitary apparatus, pharmacists and instrument makers may be extended to this exhibition. Pharmaceutical Preparations will form Class 8, and Mineral Waters Class 9, of Section II. Further information may be obtained from the official agents, Messrs. Johnson and Sons, Limited, Castle Street, Holborn.

* * *

At a meeting of the Council of the Royal Society, held on Thursday, Professor Huxley was elected to the office of President, rendered vacant by the death of the late Mr. William Spottiswoode.

* * *

The new number of the *Journal of Botany* contains the opening instalment of a biography of Samuel Dale, physician and apothecary, the neighbour, co-worker and executor of Ray, accompanied by an excellently executed portrait, apparently transferred from copper. Dale's *magnum opus* was his 'Pharmacologia,' one of the earliest systematic treatises on materia medica published in this country. The first edition appeared in 1693; it was dedicated to the "celeberrimo collegio Regali medicorum Londinensium," and its full title was: "Samuelis Dale Pharmacologia, seu manductio ad materiam medicam: in qua Medicamenta Officinalia Simplicia, hoc est Mineralia, Vegetabilia, Animalia, eorumque partes in Medicinæ officinis usitata, in methodum naturalem digesta succincte et accurate describuntur. Cum notis generum Characteristicis, Specierum Synonymis, differentiis et viribus. Opus Medicis, Philosophis, Pharmacopœis, Chirurgis, etc., utilissimum."

* * *

The annual meeting of the American Pharmaceutical Association is to be held this year in Washington, commencing on Tuesday, the 11th of September, and concluding with excursions on Saturday, the 15th. It will, therefore, precede the meeting of the British Pharmaceutical Conference, in Southport, by a week.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, July 4, 1883.

Present,—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Borland, Bottle, Butt, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

George Deller Wedge, being duly registered as Pharmaceutical Chemist, was granted a diploma, stamped with the seal of the Society.

ELECTIONS.

MEMBERS.

PHARMACEUTICAL CHEMIST.

George Deller Wedge, of Whitchurch, Hants, having passed the Major examination and tendered his subscription for the current year, was elected a "Member" of the Society.

CHEMISTS AND DRUGGISTS.

The following registered chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Flanders, Henry ....Cambridge.
Gibb, Ebenezer......................New Blyth.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Bradbury, Thomas ....Glossop.
Humphries, Jacob ....Low Moor.
Shapcott, Wm. Henry Pyne ...London.

ASSOCIATES.

The following, having passed their respective examination, and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Ashton, Frederick William......Market Harborough.
Atkins, Alfred Edward ....Newport.
Blain, William Rushton..........Bolton.
Hamilton, Henry.....................Finchley.
Handford, Thomas Edward ...Torrington.
Joye, Joseph............................Southport
Kitchin, John ....Ulverston.
Marsden, Charles Edwin.........Huddersfield.
Martin, John............................Redruth.
Nicholls, Reginald Edward......Lee.
Silk, Edward............................Macclesfield.
Thacker, Henry Ransley.........Nottingham.

Modified.

Castell, George Gower............London.
Heathcote, Henry...................Liverpool.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Bolas, Samuel Brittain ....Rock Ferry.
Coope, Thomas ....Farnworth.
Ellison, George Reed ....Whitby.
Hoyles, Henry Richardson ......Sheffield.
James, Tom ....London.
Jolly, John ....Cromer.
Lamb, Thomas ....Sleaford.
McCurrie, John ....Port Bannantyre.
Miller, Edwin Frederick..........Ipswich.
Patey, William James.............Banbury.
Smith, Arthur ....Watford.
Taylor, Walter ....London.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

Charles Cook, 36, Market Place, Wednesbury.
Charles William Hayward, Holbeach, Lincolnshire.
Frank Whitworth, 45, Etnam Street, Leominster.

ADDITION TO THE REGISTER.

The Registrar reported that—

Isaac Wilson, 74, Saltaire Road, Shipley, Yorks.,

having made a statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and this declaration having been supported by a duly qualified medical practitioner, his name had been placed on the Register.

APPOINTMENT OF PROFESSORS.

The following appointments were unanimously made:—

Professor Redwood was reappointed Professor of Chemistry and Pharmacy.

Professor Bentley was reappointed Professor of Botany and Materia Medica.

Professor Attfield was reappointed Professor of Practical Chemistry.

LOCAL SECRETARIES.

The Council went into committee to consider whether it was desirable to appoint a Local Secretary in Edinburgh, having in view the fact that there was an official of the Society there in the person of Mr. MacEwan, the Secretary to the North British Branch. On resuming, the following gentlemen were appointed Local Secretaries for the ensuing year, no one being appointed to the office in Edinburgh, in accordance to what was understood to be the wish of members in that city:—

List of Local Secretaries, 1883-84.*

Towns eligible.	Names of persons appointed.
Aberdeen	Kay, James Petrie.
Abergele	Hannah, John.
Aberystwith	Wynne, Edwin Price.
Abingdon	Smith, William.
Altrincham	Hughes, Edward.
Andover	Gould, Robert George.
Arbroath	Robertson, John.
Ashbourne	Reckless, Arthur Henry.
Ashton-under-Lyne	Arnfield, John Cash.
Aylesbury	Turner, John.
Ayr	
Banbury	Ball, George Vincent.
Banff	Ellis, Bartlett.
Bangor	Roberts, Meshach.
Barnsley	Badger, Alfred.

* Local Secretaries are appointed in all towns in Great Britain (except London and Edinburgh) which return a Member or Members to Parliament, and in such other towns as contain not less than three Members of the Society or Associates in Business.

Towns eligible.	Names of persons appointed.
Barnstaple	Goss, Samuel.
Barrow-in-Furness	Steel, Thomas.
Bath	Commans, Robert Dyer.
Beaumaris	
Bedford	Taylor, James Bennett.
Belper	Calvert, James.
Berwick	Carr, Walter Paterson.
Beverley	Hobson, Charles.
Bewdley	
Bilston	Gray, Charles.
Birkenhead	Nicholson, Henry.
Birmingham	Southall, William.
Bishop Auckland	Dobinson, Thomas.
Blackburn	Farnworth, William.
Blandford	Griffith, Samuel.
Bodmin	Williams, Joel Drew.
Bolton	Dutton, Francis.
Boston	Pilley, Henry Thomas.
Bournemouth	Duncan, Alexander.
Bradford (Yorkshire)	Rimmington, Felix M.
Brecon	Meredith, John.
Bridgnorth	Deighton, Thomas Milner.
Bridgwater	Basker, John Anthony.
Bridlington	Jackson, Henry John.
Bridport	Beach, James.
Brighton	Gwatkin, James Ross.
Bristol	Stroud, John.
Buckingham	
Burnley	Cowgill, Bryan H.
Burslem	Blackshaw, Thomas.
Bury	Bowker, Ellis.
Bury St. Edmunds	Summers, Frank.
Buxton	Thresh, John Clough.
Calne	
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Munday, John.
Cardigan	Jones, John Edward.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard Morgan.
Carnarvon	Lloyd, William.
Chatham	Crofts, Holmes C.
Chelmsford	Baker, Garrard.
Cheltenham	Smith, Nathaniel.
Chester	Baxter, George.
Chesterfield	Windle, John T.
Chichester	Long, William Elliott.
Chippenham	Coles, John Coles.
Christchurch	Green, John.
Cirencester	Smith, Charles Septimus.
Clitheroe	
Cockermouth	Bowerbank, Joseph.
Colchester	Cordley, William Bains.
Congleton	Goode, Charles.
Coventry	Hinds, James.
Cricklade	
Croydon	Barritt, George.
Darlington	Robinson, James.
Deal	Green, John.
Denbigh	Edwards, William.
Derby	Goodall, Henry.
Devizes	Edwards, Thos. Roberts.
Devonport	Codd, Francis.
Dewsbury	Gloyne, C. G.
Diss	Gostling, Thomas Preston.
Doncaster	Howorth, James.
Dorchester	Evans, Alfred John.
Dorking	Clift, Joseph.
Douglas	Brearey, William A.
Dover	Bottle, Alexander.
Droitwich	Taylor, Edmund.
Dudley	Gare, Charles Hazard.
Dumfries	Allan, William.
Dundee	Hardie, James.
Dunfermline	Seath, Alexander.

Towns eligible.	Names of persons appointed.
Durham	Sarsfield, William.
Eastbourne	Crook, Herbert.
Elgin	Robertson, William.
Ely	Pate, Henry Thomas.
Evesham	Dingley, Richard Loxley.
Exeter	Broom, William W.
Exmouth	Laugher, William.
Eye	Bishop, Robert.
Falkirk	Murdoch, David.
Falmouth	Newman, Walter Francis.
Fareham	Batchelor, Charles.
Faversham	Lenfestey, William G.
Flint	Jones, Michael.
Folkestone	Goodliffe, George.
Forfar	Ranken, James A.
Frome	
Gainsborough	Spouncer, Henry Thomas.
Gateshead	Elliott, Robert.
Glasgow	Kinninmont, Alexander.
Gloucester	Ward, Joseph.
Gosport	Hunter, John.
Grantham	Cox, John.
Gravesend	Bulgin, William.
Greenock	McNaught, Archibald.
Grimsby, Great	Cook, Robert, junior.
Guernsey	Arnold, Adolphus.
Guildford	Martin, Edward W
Haddington	Watt, James.
Halifax	Dyer, William.
Hanley	Eardley, James F.
Harrogate	Davis, R. Hayton.
Hartlepool	Jackson, William G.
Harwich	Bevan, Charles F.
Hastings and St. Leonards	Bell, James Alfred.
Haverfordwest	Saunders, David Price.
Hawick	Craig, John.
Helston	Wakeham, Charles.
Hereford	Williams, Walter.
Hertford	Lines, George.
Hexham	Gibson, John Pattison.
Hitchin	Ransom, William.
Horsham	Williams, Philip.
Huddersfield	King, William.
Hull	Bell, Charles Bains.
Huntingdon	Provost, John Pullen
Huntly	Chalmers, George.
Hyde	Wild, Joseph.
Hythe	Lemmon, Robert Alce.
Ilfracombe	Wheeler, James.
Inverness	Galloway, George Ross.
Ipswich	Anness, Samuel Richard.
Jersey	Ereaut, John, jun.
Kendal	Severs, Joseph.
Kidderminster	Gascoigne, Charles.
Kilmarnock	Borland, John.
King's Lynn	Palmer, William Joseph.
Kingston-on-Thames	Walmsley, Samuel.
Kirkcaldy	Storrar, David.
Knaresborough	Potter, Charles.
Lancaster	Bagnall, Wm. Henry.
Launceston	White, Thomas.
Leamington	Davis, Henry.
Leeds	Reynolds, Richard.
Leek	Johnson, William.
Leicester	Clark, Walter Beales.
Leighton Buzzard	Readman, William.
Leith	Finlayson, Thomas.
Leominster	Davis, David Frederick.
Lewes	Martin, Thomas.
Lichfield	Perkins, John Jaquest.
Lincoln	Maltby, Joseph.
Liskeard	Young, Richard.
Liverpool	Symes, Charles.
Longton	Prince, Arthur G.
Loughborough	Paget, John.

Towns eligible.	Names of persons appointed.
Louth	Hurst, John.
Lowestoft	Sale, Thomas J.
Ludlow	Woodhouse, George.
Lymington	Allen, Adam U.
Macclesfield	Bates, William Isaac.
Maidstone	Rowcroft, Albert E.
Maldon	Wallworth, David.
Malmesbury	Brown, Francis James.
Malton	Buckle, James.
Malvern	Metcalfe, Edmund Henry.
Manchester, etc.	Wilkinson, William.
March	Davies, Peter Hughes.
Margate	Candler, Joseph Thomas.
Marlborough	
Marlow	
Merthyr Tydvil	Smyth, Walter.
Middlesborough	Buck, Thomas.
Midhurst	Cowap, Samuel Evan.
Monmouth	Key, Hobson.
Montgomery	
Montrose	Burrell, George.
Morpeth	Marshall, George T.
Neath	Hibbert, Walter.
Newark	March, William.
Newbury	Hickman, Francis.
Newcastle-on-Tyne	Martin, Nicholas H.
Newcastle-under-Lyme	Cartwright, William.
Newport (I. of Wight)	Orchard, Herbert Joseph.
Newport (Mon.)	Phillips, John.
New Radnor	
Newtown	Owen, Edward.
Northallerton	Warrior, William.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	Bolton, Charles A.
Nuneaton	Iliffe, George.
Oldham	Hargraves, H. Lister.
Oswestry	Evans, John.
Over Darwen	Shorrock, Ralph.
Oxford	Prior, George Thomas.
Paisley	Waddell, Andrew M.
Pembroke	Treweeks, Rich. Harwood.
Penrith	Kirkbride, William.
Penzance	Cornish, Henry Robert.
Perth	Donald, David.
Peterborough	Heanley, Marshall.
Petersfield	Edgeler, William B.
Plymouth	Hearder, Henry P.
Pontefract	Bratley, William.
Poole	Penney, William.
Portsmouth, etc.	Childs, James L.
Preston	Barnes, Lawrence R.
Ramsgate	Morton, Henry.
Reading	Bradley, Charles.
Redditch	Mousley, William.
Retford	Clater, Francis.
Rhyl	Foulkes, William H.
Richmond (Yorks)	Thompson, John Thomas.
Ripon	Judson, Thomas.
Rochdale	Taylor, Edward.
Rochester	Barnaby, Henry.
Rugby	Chamberlain, Arthur G.
Ryde (Isle of Wight)	Pollard, Henry Hindes.
Rye	Waters, William Allen.
St. Albans	Ekins, Arthur Edward.
St. Andrews	Govan, Alexander.
St. Austell	Hern, William Henry.
St. Ives (Cornwall)	Young, Tonkin.
Salisbury	Atkins, William Ralph.
Sandwich	Baker, Frank.
Scarborough	Whitfield, John.
Seacombe	Walker, John Henry.
Selby	Cutting, Thomas John.
Shaftesbury	Barry, Frederic.
Sheerness	Bray, John.
Sheffield	Ward, William.
Shields, South	Mays, Robert J. J.
Shoreham	Fenner, Edwin.
Shrewsbury	Cross, William Gowen.
Slough	Griffith, Richard.
Southampton	Dawson, Oliver R.
Southport	Ashton, William.
Spalding	Shadford, Major.
Stafford	Averill, John.
Stalybridge	Brierley, Richard.
Stamford	
Stirling	Moore, William J.
Stockport	Kay, Samuel.
Stockton-on-Tees	Brayshay, Thomas.
Stoke-on-Trent	Adams, Frank.
Stourbridge	Bland, Thomas Frederick.
Stratford-on-Avon	Hawkes, Richard.
Stroud	Blake, William F.
Sunderland	Harrison, John.
Swansea	Grose, Nicholas M.
Tamworth	Allkins, Thomas Boulton.
Taunton	Gregory, George Henry.
Tavistock	Gill, William.
Teignmouth	Cornelius, Joseph.
Tenby	Davies, Moses Prosser.
Tewkesbury	Allis, Francis.
Thirsk	Foggitt, John B.
Tiverton	Havill, Paul.
Torquay	Smith, Edward.
Totnes	Michelmore, Philip W.
Truro	Percy, Thomas Bickle.
Tunbridge Wells	Howard, Richard.
Tynemouth	Stobbs, Robert.
Uttoxeter	Johnson, John Borwell.
Ventnor	Weston, Charles.
Wakefield	Wice, Jonathan E.
Wallingford	Payne, Sidney.
Walsall	Bate, Joseph William.
Wareham	Randall, Thomas.
Warrington	Greenough, Hugh F.
Warwick	Pratt, Henry.
Watford	Chater, Edward Mitchell.
Wednesbury	Gittoes, Samuel James.
Westbury	Taylor, Stephen.
West Bromwich	Stamps, Frederic.
Weston-super-Mare	Gibbons, George.
Weymouth	Groves, Thomas Bennett.
Whitby	Stevenson, John.
Whitehaven	Kitchin, Archibald.
Wick	Miller, Kenneth.
Wigan	Phillips, Jonathan.
Wigton	
Wilton	
Winchester	Hunt, Richard.
Windsor	Russell, Charles J. L.
Wolverhampton	Brevitt, William Yates.
Woodbridge	Betts, John.
Woodstock	Griffits, J. A.
Worcester	Virgo, Charles.
Worthing	Cortis, Arthur Brownhill.
Wrexham	Edisbury, James Fisher.
Wycombe	Furmston, Samuel C.
Yarmouth, Great	Poll, William S.
Yeovil	Maggs, Thomas Charles.
York	Sowray, Joseph.

Examiners for Council Prizes.

Mr. Plowman and Mr. Southall were unanimously appointed to conduct the next examination for the Council Prizes.

Written Examinations.

The Registrar presented the following table, showing the attendance of candidates at the various centres for the last eleven Preliminary examinations, and it was resolved that Superintendents be appointed at the same centres as last year, the appointments to be offered in the first instance to the Local Secretary in each of those places, with the exception of London and Edinburgh.

PRELIMINARY EXAMINATION.

List of Centres and Table of Attendances of Candidates at each Centre.

	1881. Jan., Apl., July, Oct.	1882. Jan., Apr., July, Oct.	1883. Jan.	1883. Apr.	1883. July.	Total number of attendances at each centre at 11 examinations.

Reports of Committees.

FINANCE.

The report and recommendations of this Committee were received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow of a pharmaceutical chemist and member for many years, Applicant has had five previous grants.

£10 to the widow of an associate who has had five previous grants.

£10 to a registered chemist and druggist, aged 69, suffering from heart disease.

£10 towards the support of two of Isherwood's orphans.

One application had been deferred for further consideration.

The report and recommendations were received and adopted.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Librarian's Report.

This report of the Librarian had been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
May	Day	692	37	16	26
	Evening	161	14	2	7

	No. of Entries.		
Circulation of books.	Town.	Country.	Total.
May	186	116	302

Carriage paid, £1 13*s.* 6½*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Hogg (W. D.), La Médecine publique en Angleterre, 1883. From the Author.

Ince (J.), Latin Grammar of Pharmacy, 2nd ed., 1883. 2 *copies.* From the Author.

Poehl (A.), Über das Vorkommen und die Bildung des Peptons ausserhalb des Verdauungsapparates und über die Rückverwandlung des Peptons in Eiweiss, 1882.

— Mittheilungen über neue Arzneimittel.

— Three pamphlets in Russian. From the Author.

United States, Medical and Surgical History of the War of the Rebellion, part 3, vol. 2, 1883. From the Surgeon-General, U.S. Army.

The Committee also recommended the purchase of the undermentioned works:—

Armstrong (H. E.), Organic Chemistry, 3rd ed., 1882.

Bloxam (C. L.), Chemistry Inorganic and Organic, 5th ed., 1883.

Ralfe (C. H.), Demonstrations in Physiological and Pathological Chemistry, 1880.

Neubauer and Vogel, Analysis of Urine, latest edition.

Owen (I.), Materia Medica, 1883.

Proctor (B. S.), Practical Pharmacy, 2nd ed., 1883. 2 *copies.*

Pharmaceutical Times, 1847-8, vol. 3.

Illustrations of the British Flora, companion to Bentham's Handbook, 1880.

Bentley (R.), Student's Guide to Botany, 1883.

Tolhausen (A.), Technological Dictionary in English, French and German, 3rd ed., 1883.

The Committee also recommended for purchase, a cabinet containing, on separate slips, over 10,000 titles of books, etc., prepared with a view to the formation of a bibliography of pharmacy.

The Committee also recommended that the Library and Museum be closed in the evening during the months of August and September, and that they be closed entirely on Monday, August 6.

Curator's Report.

The Curator had reported that the attendance in the Museum during the month of May had been:—

	Total.	Highest.	Lowest.	Average.
Morning	484	32	0	19
Evening	112	12	0	5

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimens of English rhubarb prepared from the root of *Rheum officinale.* From Mr. R. Usher, Banbury

Specimens of crystals of Glycocoll.
From Mr. T. S. DYMOND.
Specimens of the root of *Chondodendron tomentosum*, and of the bark of the Balsam of Peru tree.
From Messrs. HEARON, SQUIRE and FRANCIS.
Specimen of the juice of the Natal Aloe plant.
From Mr. T. W. TURNER, Pietermaritzburg.
Specimen of the leaves of *Angræcum fragrans*.
From Messrs. WRIGHT, LAYMAN and UMNEY.
Specimen of Boldu leaves (*Cryptocarya Peumus*).
From Messrs. T. CHRISTY and Co.

The Professors had attended and reported satisfactorily of their respective classes.

New cases for Museum specimens were recommended to be placed in the front examination room, and it was also recommended that the examination rooms be cleaned and painted in accordance with an estimate that had been obtained.

The list of Local Secretaries had been considered and settled, subject to the approval of the Council.

The President had been requested to ask Professor Michael Foster, F.R.S., to deliver the Inaugural Address in October next.

The report and recommendations were received and adopted.

The Inaugural Sessional Address.

The PRESIDENT announced that he had seen Professor Michael Foster, who had consented to deliver the address.

FREEHOLD INVESTMENTS.

The report of this Committee was read, giving particulars of ground rents which had been considered by the Committee, who recommended the purchase of properties yielding £407 per annum; one property, yielding £37 per annum, had already been purchased in pursuance of a resolution formerly passed.

The Council went into committee to consider the subject, when the President read the report of a firm of surveyors who had inspected the property.

A long discussion ensued.

On resuming, the report and recommendations were received and adopted.

THE NEW PATENTS BILL: THE USE OF THE ROYAL ARMS.

Mr. SYMES drew attention to the fact that by section 94 of the new Patents Bill, now before the Grand Committee of the House of Commons, it is provided that anyone who without due authority used, in connection with any trade or business, the royal arms or any colourable resemblance thereto, shall be liable to a fine not exceeding £20. If the Act were passed this session, as was expected, it would come into operation in January next. It had occurred to him that many chemists and druggists were in the habit of using the royal arms on their labels, and that their stock might not be exhausted by January next. He would ask whether it would not be as well for the Council to make a suggestion to the Committee that the operation of the clause should be deferred to a later period.

Mr. BUTT said he had the royal arms painted on a specie jar, which he presumed would be illegal under such an Act.

Mr. YOUNG said he believed there were many labels used bearing the royal arms, and it might be as well to see if anything could be done.

Mr. SCHACHT said the utmost the Council could do would be to ask for an extension of the time; the clause itself seemed to be a very proper one.

The PRESIDENT said he would bring the subject before the Library, Museum, Laboratory and House Committee at its next meeting.

GENERAL PURPOSES.

The report of this Committee, which was read in committee, included the usual letter from the Solicitor stating the progress of cases which had been placed in his hands. The result in the cases of Everard Arthur Brown and J. C. Copley, both of Nottingham, was reported in the Journal of the 23rd ult. A penalty had also been paid by

Owen Stafford, of Hyde, Cheshire.

Several cases of alleged infringement of the Pharmacy Act had been reported, and in some instances legal action was recommended. In one case the Secretary had received information of a proposed sale of drugs by auction in which some poisons were to be included, but on making representations to the auctioneers, these poisons were withdrawn from the sale.

The report and recommendations were received and adopted.

REPORT OF EXAMINATIONS.

June, 1883.

ENGLAND AND WALES.

	Candidates. Examined.	Passed.	Failed.
Major (20th)	6	1	5
Minor (20th)	19	7	12
„ (21st)	22	12	10
	—41	—19	—22
Modified (21st) . . .	2	2	0

Preliminary Examination.

Twenty-three certificates had been received in lieu of the Society's examination:—

7 College of Preceptors.
2 Faculty of Physicians and Surgeons of Glasgow.
1 Royal College of Surgeons of England.
1 Royal University of Ireland.
1 Society of Apothecaries.
7 University of Cambridge.
1 „ Glasgow.
1 „ London.
2 „ Oxford.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, June 28, 1883, Mr. H. G. Greenish, Vice-President in the chair.

Mr. H. Hamilton read a paper upon "The Characteristics of the Principal Natural Orders," in which the leading characters of the chief natural orders were explained. The paper was profusely illustrated by fresh specimens of typical plants.

A discussion followed the reading of the paper, in which the Chairman, Messrs. Baily, Corder, Crow, Fowler, Granger, Ranken and Short took part.

A vote of thanks was passed to Mr. H. Hamilton.

The Reporter upon Analytical Chemistry, Mr. C. Thompson, then made a report upon "The Estimation of Carbolic Acid," in which he gave an account of the principal processes, both gravimetric and volumetric, which have been proposed for the determination of carbolic acid, as well as a description of experiments made by the author to determine the relative accuracy of the respective processes.

In the discussion that followed, the Chairman, Secretary, Messrs. Crow, Dymond, Ranken and Short took part.

The meeting then adjourned.

Parliamentary and Law Proceedings.

Improper Use of Arsenic.

LAYING POISON ON A FARM.—HEAVY PENALTY ON A RATCATCHER.

At the Broxton (Cheshire) Petty Sessions, Joseph Turner, a ratcatcher, was charged with having illegally exposed poison on land.

Mr. Cartwright, who appeared for the police, said the defendant for some time before May 28 had been in the neighbourhood of Newton-by-Tattenhall killing rats, and about that period dogs, cats and game were found dead in the district. The first idea was that the animals had been killed by some fanatic who had a design on them; ultimately, however, Sergeant Morgan discovered, by a hedge on a farm, a substance which he suspected contained poison. He also noticed it in several other places, and there were traces of it beside a pool of water. He took up a quantity, and it was forwarded to the county analyst, Dr. Carter Bell, who stated that it contained 10 per cent. of arsenic, 3 grains of which would be sufficient to kill a man. Traces of this deadly poison had been discovered in the bodies of foxes which had been found dead in the district, and it was impossible to imagine what might be the result of laying such poison on a farm recklessly. It might be picked up by domestic animals, and in that way many deaths might ensue. It was well known that when rats took the poison they usually made for the water, and pools of water might be thus poisoned. The police had not been able to discover who had sold the arsenic to the defendant, but undoubtedly the vendor was even a greater offender than the defendant, for the analyst found that the arsenic was unmixed, whereas the law prescribed that it should be mixed with soot or indigo before it was sold.

Walter Sadler, a farmer, having proved that he had seen the defendant lay the poison, a fine of £13, including costs, was imposed.

[*** The inference drawn respecting the vendor of the arsenic is not necessarily correct, since the sale of uncoloured arsenic in quantities of not less than ten pounds at a time is provided for in section 4 of the Arsenic Act.—Ed. Ph. Journ.]

Poisoning by Vermin Killer.

Last week an inquest was held in Lincoln, by Mr. S. Lowe, City Coroner, concerning the death of a girl, named Pepper, aged 16 years, who had committed suicide. It appeared from the evidence that the deceased, having been reproved by her father for her unsatisfactory conduct, had been observed, after she had gone to bed, to be taking something from a paper, which was thought to be sweetstuff, but very early the next morning she was found in dreadful contortions, and died shortly after in fearful agony. It was subsequently ascertained that on the previous evening she had purchased a packet of "Battle's Vermin Killer," and the wrapper round the packet was found under her pillow.

Lucy Hodson was called, but, being only 13 years of age, she was not sworn. She, however, made the following statement: Last night, a little before six o'clock, I went with Mildred Pepper to Messrs. Battle and Maltby's shop for a threepenny packet of "Vermin Killer." She said to the assistant "If any of the children eat it, will it poison them?" and the answer was, "Yes, it is rank poison." She told the person in the shop she wanted it to put in the cupboard to kill the mice.

The medical evidence showed that death had resulted from strychnine poisoning, and the Jury returned a verdict that deceased had committed suicide by taking poison whilst in a temporary state of insanity.—From the *Lincolnshire Chronicle*.

Poisoning by Carbolic Acid.

On June 27, at Liverpool, Mr. Clarke Aspinall inquired into the circumstances attending the death of James McBroom, a commercial traveller. It appeared from the evidence that deceased was a very intemperate man, and had not been sober within the last three weeks. His head had become affected, and on Friday last he attempted to take poison, but was prevented. On Monday he returned to the house helplessly drunk about six o'clock, and half an hour afterwards his landlady found him dead in bed. A carbolic acid bottle lay on the table, and it transpired that he had purchased some of that poison on Monday morning, telling the chemist that he wanted it to dissolve horn pith. Dr. Sheppard, who was called in to see the deceased, stated that the cause of death was carbolic acid poisoning.

The Coroner remarked that every care had been taken in the sale of the carbolic acid; in fact, he found chemists generally were very careful in the conduct of their business, and that during the sixteen years he had been Coroner for Liverpool no case of poisoning had come before him in which a chemist had sold the article carelessly."

The Jury returned a verdict of "Suicide during temporary insanity."

Curious Action against a Chemist.

C. WEIGHT *v.* WALTER R. HADWEN.

This was an action heard last week at the Weston County Court, by Mr. W. J. Metcalfe, judge, in which the plaintiff, a travelling theatrical proprietor, claimed £5 of the defendant, a chemist, of Highbridge, for the loss of a dog, from taking poison on the defendant's premises. According to the statement of the case for the plaintiff, he had occasion to go to the defendant's shop. The dog followed its master into the shop, and the door of the counter being open at the time, the dog got into a place behind it, where Mr. Hadwen or his assistant had placed poisoned bread and butter on the floor with a view of killing mice or vermin, and the dog getting hold of it was killed in a very few minutes. It was contended that the defendant had been guilty of carelessness, in allowing particles of poisoned bread to be about his shop, within the reach of any child or dog that might come in. The dog was a retriever and performed in some of the pieces in the theatre.

Mr. Hadwen, in defence, having explained the position of the counter and the opening in the same, which was nearly at one end of the shop, said a piece of poisoned bread had been placed on the day in question on the top of a hamper at the extreme corner of the shop, about five minutes before the dog took it up. The greatest care had been exercised in placing the bread on the hamper, as the assistant who placed it there intended to take it away and burn it. Whilst his assistant was attending to the plaintiff, the dog, which did not appear to be under full control, got behind the counter and seized the piece of bread which was on the hamper either by stretching its neck or standing on its hind legs. Witness said he had to dispense and manufacture poison constantly for agricultural purposes, and as the rear of a chemist's counter was a sacred spot, the public had no right there. Chemists were bound as qualified men to keep such counters, and as every intelligent person knew that he had no right behind such counter, he ought to take care that an unintelligent brute should not go there. If the plaintiff's dog was a valuable creature, that was the greater reason why more care should have been taken of it. He denied the charge of carelessness which had been preferred by the plaintiff. Supposing that dog had come into his shop and knocked down some valuable bottles, would not its master be responsible? If the owner of the dog was responsible in that instance, why surely it was in the present action. Witness added that when the dog took the poisoned bread the assistant at once took the bread out of its mouth, and the plaintiff took the dog away from the shop apparently none the worse for what had happened.

In cross-examination Mr. Hadwen said he was in the room behind his shop when the plaintiff and his dog entered, and he heard the whole of the conversation between the plaintiff and his assistant. There was no need to put the poisoned bread on a higher elevation, as the dog had no right whatever behind his counter. The poisoned bread had been in a seed drawer the whole of the night before, and had only been placed about five minutes on the hamper, prior to its being burned. His assistant had just taken the bread from the drawer in order to put a fresh piece in its place, when a customer entered the shop. They were obliged to put a fresh piece of poisoned bread every night to destroy mice, as mice would not touch stale bread. The dogs which came to his shop were a great nuisance, as they had spoiled a lot of his goods from time to time, and he hoped that the accident which had happened to the plaintiff's dog would be a lesson to all his customers. As the plaintiff knew that he was a dispenser and manufacturer of poisons he ought to have taken proper care of his dog.

Mr. Hadwen's assistant corroborated his employer's statement.

His Honour, in summing up, pointed out that it had been held that the proprietor of a theatre was not at all liable when a person, who had no business on the stage, fell through a trap door, whereby he sustained bodily injuries. And so, if a person brought a dog with him into a chemist's shop, where there are all sorts of things necessarily exposed, he did so at his own risk. Mr. Hadwen had not invited the dog into his shop. Dogs are no doubt great nuisances to shopkeepers, and if people would take their dogs about into chemists' and other shops they would do so at their own risk. Even if the dog had picked up the poison outside the counter, he would have been loath to hold Mr. Hadwen responsible. Mr. Brice could take the case into a higher court if he liked, but it was his opinion that the defendant was not responsible in the present instance.

Judgment for the defendant, with costs.—*Weston Mercury and Somersetshire Herald.*

The Limitations under which a Man may use his own Name as a Trade Mark.

An important decision, bearing upon the law as to trade marks, was given last week by Mr. Justice North, in the case of Freeman *v.* Freeman. The action was to restrain the defendant from selling, offering for sale, passing or attempting to pass off, or enabling or inducing others to pass off baking powder not of the manufacture of the plaintiffs as or for the goods of the plaintiffs, by using the word "Freeman" or in any other way. The facts will be sufficiently understood from the judgment, which was as follows:—

Mr. Justice North said the plaintiffs (Freeman and Hildyard) had for many years carried on the sale of Freeman's baking powder, and in 1876 they registered as a trade mark the front of the label now used upon the 1*d.* packages. From the evidence it appeared clear that the sale of this baking powder became very large, one witness putting the number of packets sold at ten or eleven millions in the course of a year. To obtain this trade they had advertised very largely, and issued a considerable number of show-cards, and the article sold by them had become recognized in the trade, and was invariably asked for by customers as "Freeman's." On the label appeared the following words:—"Freeman's Digestive Baking Powder," the word "Freeman" being printed large, and then the words "Try it," which were said to be registered, and below that two medals and the signature "W. G. Freeman." The defendant's position was this. He seemed to have carried on business for some time as a china and glass merchant, and then he took up the ironmongery business. In September, 1880, he added to that the business of an oil and colourman, provision dealer, and other matters of that kind, and he had his name painted up in three or four places on his premises in the Harrow Road. He then for the first time commenced to deal in baking powder, and with the exception of three small fancy boxes which he had from Messrs. Pearce Duff and Co., the baking powder was supplied by the plaintiffs. The defendant himself proved that he knew the plaintiffs' article, for he had produced his invoices in which the baking powder was described as "Freeman's." In February or April the defendant commenced to make baking powder; at first he sold it in 1*d.* packets, afterwards adopted the 2*d.* packets, and the 1*d.* packets were very like the plaintiffs'. By "very like" he meant the packet was of the same size, the paper was of the same colour, the inscription on the back was in the same coloured ink, and at first sight no one could say which was the plaintiffs' and which was the defendant's. Upon examining the packet closely it would be seen that the words were different. On the top were the words "Royal Baking Powder" "Is the Best," then the royal coat of arms, and "Prepared only by H. Freeman, manufactory, College Park, Harrow Road, London, W." No doubt a person comparing the two packets would be able to distinguish between them, and would not be misled; but it must not be forgotten that very often persons had not the two labels side by side. Therefore, the mere fact that the distinction could be seen when the two were examined together was not all important. Of course, the defendant had a right to place his name and address upon his goods, so that persons might know where to apply to; but it was important to notice that the address was in very different type and appearance to the name. The name, "H. Freeman," was printed in enormously large letters, considering the size of the packets, and the address was printed in small letters. His lordship having referred to the evidence as to the sale of the defendant's baking powder to the plaintiffs when "Freeman's" was asked for, said he believed the defendant had sold this packet with the intention of passing it off as the plaintiffs' manufacture. It was clear that the plaintiffs' baking powder was known by the name of "Freeman's"; it was clear that the defendant had a right to sell baking powder, and to use his own name and address, but it was incumbent upon him to use his own name in such a way as not to represent that the goods made by him were really the goods of somebody else. He thought that the name of "H. Freeman" had been placed in a conspicuous manner upon the packages by the defendant in order to identify his baking powder with the name of Freeman. In addition to that there was the fact of the packets being of the same size, the boxes of the same shape and size, and the advertising that the powder was sold in 6*d.* and 1*s.* tins, when upon the defendant's own evidence he had never sold any tins. He also thought that the use by the defendant of the plaintiffs' show cards had not been sufficiently explained, and, therefore, he should grant an injunction restraining the defendant from selling, or offering for sale, or attempting to pass off any baking powder not manufactured by the plaintiffs as and for the goods of the plaintiffs. The defendant would also be restrained from using the label which had been put in evidence, and must pay the costs of the action. Upon the application of counsel for the plaintiffs his lordship directed the usual account as to profits, if the plaintiffs elected to proceed with it.

Reviews.

THE STUDENT'S GUIDE TO STRUCTURAL, MORPHOLOGICAL AND PHYSIOLOGICAL BOTANY. By ROBERT BENTLEY, F.L.S., M.R.C.S. Eng., etc.*

In consequence of the rapid strides made in all branches of botanical science during the last twenty years, the size of manuals of botany has, almost of necessity, increased in proportion, until they have become both too condensed in matter and too voluminous in size to be suitable either for regular reading, or for carrying with comfort in the pocket or hand. They have, therefore, in many cases become simply works of reference. Probably for this reason, many old pupils and others have expressed a desire, for some years past, to Professor Bentley, "to have a guide which should serve as an introduction to his Manual and other larger and more comprehensive works." In accordance with this expressed wish, Professor Bentley has prepared the volume under notice, in which he has "endeavoured to condense within a moderate compass all that is essential for a foundation for future study, with the view of its forming a convenient and trustworthy, but not too elementary, guide to structural and physiological botany, for medical and pharmaceutical students, and also for use in colleges and schools, where botany is now largely taught."

The book is of convenient size for the pocket, being rather smaller than Thomé's 'Text-book.' Systematic botany is entirely excluded, for the present volume is to be followed as early as possible by another, entitled 'The Student's Guide to Systematic Botany,' uniform with it in design and execution. This separation of the manual into two parts, each brought up to date by careful revision, will prove a great boon to students, since the two parts are rarely used at the same time. On opening the pages of the present volume it will be observed that, with the exception of one or two figures after Sachs, Luerssen, and others, the illustrations are those of the Manual. A perusal of the text, however, will show that many new terms are added and that nearly every page bears evidence of careful revision; this is particularly the case with regard to the style and language, which is much more simple and perspicuous than it was possible to make it in so condensed a work as the Manual. For instance, the summary of the discoveries of Darwin and others on the movements of plants is presented in a manner that renders it quite a bird's-eye view of the subject.

The great improvements made in the 'Student's Guide' over the first part of the Manual lead to the hope that the highly esteemed author may proceed still further in the next edition, which we trust may soon follow. From very few botanical works, if, indeed, from any, does the student gain an idea of the relative frequency with which the immense number of terms are used by systematic botanists, or of the looseness with which certain words, such as achene, thorn, berry, etc., are used, while there are many words met with in Latin descriptions of plants of which he has a difficulty in finding out the meaning in a Latin dictionary. A little more information in this direction would lighten to a considerable extent the difficulties of the students in the practical study of the science.

The 'Student's Guide' well deserves its name, for it serves as an intermediate stage between the cheap elementary primers and the perusal of such a complete text-book of the science as Sachs' classical work. The student who has carefully gone through the little volume now under notice will find himself familiar with the numerous new terms to be met with in the most advanced works on the subject, and will be thus fully equipped for further research which, in such subjects as chlorophyll, the reproduction of the Florideæ, and the colouring matters of plants, must be carried on in more advanced and compendious treatises. To the student we can strongly recommend the 'Student's Guide,' and also to those whose who from pressure of business have not time to read all that is written in botanical science, but who find an acquaintance with the meaning of new terms, which come into use almost every year, necessary to prevent their being left behind in the march of scientific knowledge.

DIE CHINARINDEN. In Pharmakognostischer hinsicht dargestellt von F. A. FLUCKIGER.*

This is a concise handbook on the cinchona bark, and supplies a want which has long existed of an accurate condensation of the literature of the cinchonas suitable for pharmaceutical readers. Originally appearing in the author's 'Pharmakognosie des Pflanzenreiches,' Professor Flückiger has supplemented his article with such matter as the work required in its present form and was of interest to a wider circle of readers.

Commencing with a botanical description of the genus *Cinchona* and of the most important species, then of the genus *Remijia*, next come chapters on the habitat and the cultivation of the cinchona and on the collection of the bark and the effect of mossing, coppicing and uprooting. Then follow accounts of the appearance and structure of the bark, of the contents of its tissues and the seat of the alkaloids; also of the various kinds of cinchona barks. Chapter XI. contains an interesting description of the now important cuprea bark, the name first applied by the author in 1871 to the bark of a species of *Remijia*. Since its introduction in about June, 1879,—although according to a foot note on page 43, Mr. J. E. Howard has shown to the author a specimen of cuprea bark which he obtained on the London market in 1859,—the importation of cuprea bark has increased to such an extent that the greater part of the cinchona bark which is now imported from South America consists of cuprea, and its value as a quinine bark cannot be too highly estimated as it yields on an average one and a half per cent. of quinine alkaloid with a very small proportion of quinidine and cinchonine and no cinchonidine. There is a well-written account of the chemical constituents of cinchona bark, with the list of the alkaloids brought down to the latest date, including the new alkaloid of cuprea bark, discovered in 1881 and first published in this Journal in December of that year; we refer to homoquinine, ultraquinine, or cupreine, whichever may be the name finally adopted for it. We notice Professor Flückiger adopts Skraup's new formula for cinchonine and cinchonidine, viz., $C_{19}H_{22}N_2O$.

The chapter on the quantitative determination of the alkaloids contains several ready pharmaceutical methods for the estimation of the amount of alkaloids in cinchona bark without regard to the separation of the mixed alkaloids, the amount of quinine in which would hardly be very accurately ascertained by dissolving the mixed alkaloids in ether (or chloroform) and relying on "the weight of the residue left after the evaporation of the ether approximating to the quantity of quinine" ("das Gewicht des nach Verdunsten des äthers bleibenden Rückstandes entspricht annähernd der Menge des Chinins," p. 60), or by neutralizing the alkaloids with sulphuric or tartaric acid and depending on "the corresponding salts of quinine being, on account of their difficult solubility, easy to separate from those of the accompanying alkaloids" ("die entsprechenden Salze des Chinins sind ihrer Schwerlöslichkeit wegen leicht von denjenigen der Nebenalkaloïde zu trennen," p. 61).

The book has some excellent plates illustrating the plants of *C. succirubra*, *C. Calisaya*, var. *Ledgeriana* (2), *C. lanci-*

* Berlin: R. Gaertner, 1883. Super Royal 8vo. Pp. 1–79. Plates I.–VIII. 10*s.* 6*d.*

folia, *C. officinalis*, *Remijia pedunculata*, sections of the bark of *C. Calisaya* and *C. lancifolia* and a section of the "cuprea" bark, and is written with the care that usually characterizes the works of Professor Flückiger.

Obituary.

Notice has been received of the death of the following:—

On the 19th of April, Mr. James Garrett, Chemist and Druggist, Commercial Street, Newport, Mon. Aged 77 years.

On the 4th of May, Mr. John Dodwell, Chemist and Druggist, Camberwell New Road, S.E. Aged 79 years.

On the 11th of May, Mr. William Duncanson, Pharmaceutical Chemist, Port Street, Stirling. Aged 52 years. Mr. Duncanson had been a Member of the Pharmaceutical Society since 1869, and for several years filled the office of Local Secretary.

On the 30th of May, Mr. Edward Dingle, Chemist and Druggist, Bideford. Aged 82 years.

On the 4th of June, Mr. Richard Graves, Chemist and Druggist, Broad Street, Golden Square, W. Aged 26 years. Mr. Graves had been an Associate of the Society since 1880.

On the 6th of June, Mr. Webster Cox, Chemist and Druggist, Havelock Place, Stoke-on-Trent. Aged 21 years.

On the 11th of June, Mr. Frederick George Baldwin, Greenwich Road. Aged 36 years.

On the 16th of June, Mr. George Smith F. Skoulding, Chemist and Druggist, Church Plain, Great Yarmouth. Aged 48 years.

On the 19th of June, at Ilkley, Mr. Samuel Hague Stanley, late of Bradford. Aged 73 years.

On the 21st of June, Mr. Joseph William Winter, Chemist and Druggist, Boxford, Suffolk. Aged 56 years.

On the 22nd of June, Mr. William David Williams, Chemist and Druggist, High Street, Hampstead. Aged 41 years.

On the 22nd of June, Mr. John Nelson, Chemist and Druggist, Bridge Street, Blyth. Aged 85 years.

On the 22nd of June, Mr. William John Mortlock, Pharmaceutical Chemist, Huntingdon. Aged 27 years.

On the 27th of June, Mr. John Sharp, Chemist and Druggist, Sedgefield Terrace, Bradford. Aged 76 years.

On the 28th of June, Mr. Horatio Pass, Chemist and Druggist, Wandsworth Road, S.W. Aged 69 years. Mr. Pass had been a Member of the Pharmaceutical Society since 1869.

On the 30th of June, Mr. Robert Stephen, Chemist and Druggist, George Street, Aberdeen. Aged 39 years.

On the 2nd of July, Mr. Frederick Kendall, Stratford-on-Avon. Aged 75 years. Mr. Kendall was one of the Founders of the Pharmaceutical Society, having joined it in 1841.

EASTON'S SYRUP.

Sir,—In the Journal for April 26, 1879, Mr. Edward Smith, in a remark on Mr. Gilmour's note on the loss of quinine in making Easton's syrup, suggested the direct use of the sulphate instead of the phosphate prepared from it.

Would you kindly allow me to ask Mr. Smith, or any one who may have acted upon his suggestion, whether or not they have succeeded in turning out a satisfactory syrup. I find that Easton's syrup, prepared strictly from the sulphate or from crystallized phosphate, soon becomes unsaleable from the presence of minute crystals which give the syrup a "milky" appearance.

Information from any who may have met with similar difficulties would be very acceptable.

JOHN.

REJECTED BARK OF "TR. QUILLAYA SAPONARIA" AS A CLEANSING AGENT.

Sir,—To those who are in the habit of making their own tincture of the above it may be interesting to know that the "bark," having done its duty in forming the tincture, comes very useful for cleansing greasy bottles, etc. I always find it answer capitally; just a small piece and a little water do wonders.

J. D. M.

SYRUP OF SQUILLS.

Sir,—This preparation, if made with sugar, invariably crystallizes, and consequently is never uniform.

I have for some years made a syrup which never alters; it is perfectly transparent, and I hope the formula will find a place in the New Pharmacopœia. It is as follows:—Mix, by stirring, 15 ozs. by weight of syrup of glucose with 2 fluid ounces of glycerine. Now add 10 fluid ounces of acetum scillæ, and stir until thoroughly incorporated, no heat being used.

PERCY WELLS.

Lac.—A recipe for essence of rennet will be found in the *Pharm. Journ.* for August 19 last, p. 150.

Spicelia.—There would be no difficulty in obtaining a copy of the second edition of Mr. Ince's book if you were to apply directly to the publishers, Messrs. Baillière, Tindall and Cox, 20, King William Street, Strand, W.C.

H. C. H.—The plant has been named correctly.

"*Cornkure.*" — Such a preparation has been held by the Inland Revenue Authorities to be liable to the payment of stamp duty.

American.—There are almost as many rival recipes for Florida Water as for Eau de Cologne. The following is one of them:—Ol. lavand., ol. bergamot., ol. limonis, of each 2 drachms; tinct. curcumæ, ol. neroli, of each 1 drachm; ol. melissæ, 30 drops; ol. rosæ, 10 drops; alcohol, 2 pints.

R. A. Hoyle.—No. 5 is *Scirpus acicularis*; the others are correctly named.

Ephemera.—(1) *Euphorbia Peplus.* (2) *Carex pseudo-cyperus.* (3) *Vicia sepium.* (4) *Scrophularia aquatica*, probably: leaf and stem should be sent.

"*Herbalist.*"—(1) *Verbascum Thapsus.* (2) *Rhinanthus Crista-Galli.* (3) *Polygala vulgaris.* (4) *Prunella vulgaris.* (5) *Galium Aparine.* (6) *Scrophularia nodosa.*

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Browne, Messrs. Bennett, Wells, Darling, Stanford, Inquirer, G. H. P.

SEEDS OF THE CAMELLIA OLEIFERA (C. DRUPIFERA, HOOKER).

BY HUGH MCCALLUM.

The *Camellia Oleifera* grows abundantly on the hill sides throughout the Kwangtung province and is to be found over the greater part of China. A full botanical description of it is given in Hooker's 'Flora of British India,' which is now being published. Some of the seeds were collected about fifty miles north-east of Hongkong. Freed from the husk, a sample of them yielded 44 per cent. of a somewhat viscid yellowish oil, odourless and having an unpleasant after-taste. The method of extraction was with ether, using a Soxhlet's tube. The oil is practically insoluble in 84 per cent. alcohol. It is a commercial article under the name of Cha Yau, or tea oil, and is popularly thought to be obtained from the tea tree. The fact of the character Cha being used for both plants is doubtless the cause of the error. It is chiefly used as a hair dressing and as an illuminant. Bentley states that it makes a good salad oil, but all the specimens seen have been quite unfit for such a purpose, owing to their unpleasant taste. Expression is the method adopted by the Chinese for extracting the oil. In addition to the oil about 10 per cent. of a glucoside, giving most of the reactions of saponin, was obtained from the seeds. Even then, the marc on shaking with water gave an abundant persistent lather, indicating that all the saponaceous principle had not been extracted.

Cha-tsai-fau.—This is a rough greyish powder having a faint peculiar odour, the dust irritating the nostrils. It appears to be the powdered residue obtained in expressing the oil from the seeds of the *Camellia oleifera.* It is chiefly used as a washing powder, more especially for removing greasy stains. An infusion of it is used by gardeners for destroying worms, grubs, etc., and it is reported to answer the purpose well. It is sometimes used for poisoning fish and it acts with certainty when the fish are in tanks with only a limited supply of water, as is often the case in China, but it is doubtful if it would prove as effective in a running stream. It contains the same glucoside as the *Camellia Oleifera* seeds, and also a small quantity of an oil soluble in rectified spirit, having an odour resembling linseed oil and a very unpleasant taste.

Cha-tsai-peng.—This is a rough, thin, almost circular cake covered with rice husks. It appears to be the same thing as Cha-tsai-fau in a coarser form and contains the same glucoside. It is used with water as a hair wash.

Saponin from the Seeds of Camellia Oleifera.—This is a friable amorphous powder of nearly a pure white colour having only a slight creamy tinge. It is almost odourless when dry, but it has a peculiar somewhat disagreeable odour when dissolved in water. The dust irritates the nostrils. It is hygroscopic and when perfectly dry adheres to the tongue similar to hydrated alumina. Its taste is at first sweetish, resembling liquorice, then bitter and disagreeable, causing a peculiar biting sensation in the throat. It is insoluble in ether, sparingly in absolute alcohol, freely in 84 per cent. alcohol and very soluble in water. Its solution in water has a distinct acid reaction to litmus paper. A watery solution gives white precipitates with barium hydrate and basic lead acetate, none with normal lead acetate in the cold, but a white one on heating. With Fehling's solution it gives a greenish precipitate and on boiling a slight reduction takes place. Heated with dilute hydrochloric acid a floculent white precipitate (sapogenin) is thrown down and a glucose remains in solution. The watery solution emulsifies oils and chloroform, and when shaken in a tube with mercury, the mercury is reduced to a fine grey powder. On incineration it gives 0·9 per cent. of ash.

After several unsuccessful attempts to obtain the glucoside in a pure state, the following method was finally adopted:—The seeds were sliced as finely as possible and the oil removed by ether, using a Soxhlet's tube. The marc was then reduced to powder and exhausted by repeated treatment with boiling 84 per cent. alcohol. The alcoholic solution so obtained was concentrated to a syrupy consistence and gradually poured, with constant stirring, into absolute alcohol. The glucoside separated as a floculent precipitate speedily subsiding and cohering into a brownish sticky mass. This was redissolved in warm 84 per cent. alcohol, digested with animal charcoal, filtered and evaporated to dryness. The substance thus obtained may not be quite pure, and this probably accounts for its not altogether agreeing with saponin derived from other sources. One notable point of difference between it and the *pure* saponin, obtained by Mr. H. Collier from the bark of *Quillaia saponaria*, is the low figure for ash, viz., 0·9 per cent. compared with 3·979 per cent., agreeing, however, in being composed chiefly of calcium.

The poisonous effects on the smaller animals, which this substance undoubtedly possesses, suggests its use as a vermifuge and it is to be hoped a trial will be made with it.

Hongkong, China.

SOURCE OF THE PUNGENCY IN TINCTURE AND LINIMENT OF IODINE.

BY W. H. DARLING.

In this Journal* MacEwan has called attention to the pungency of some liniment made with methylated spirit, and showed by experiment that *pure* methyl alcohol does not develop this peculiarity. He therefore attributes it to the allyl alcohol in the crude wood spirit. In Canada,† Gregory, having noticed the same pungency in some tincture of iodine made with methylated spirit, agrees with MacEwen in attributing it to the allyl alcohol, observing "that the odour of the tincture was decidedly garlicky."

That allyl alcohol is one of the constituents of wood spirit, Aronheim‡ has shown, although Dancer§ does not mention it, for he gives the constituents of rough wood spirit as methyl alcohol, methyl acetate, acetone and bimethyl acetal.

The allyl compounds are characterized by pungency, but they will not be the only pungent compounds present in these preparations when made with methylated spirit, for the halogen substitution products of acetone, present in considerable quantity in crude wood spirit, are of an extremely irritating nature, much beyond the allyl compounds in this particular. It is to acetone rather than to the allyl alcohol must be attributed the pungency noticed in these iodine preparations when made with methylated spirit.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from Vol. XIII. p.* 1057.)

Chemical Materia Medica.

Acida.—The already long list of acids in the United States Pharmacopoeia has been increased, five having been introduced and only two omitted. The new acids are—glacial acetic, boric, dilute hydrobromic, oleic and salicylic acids; those omitted are—oxalic and valerianic acids. Glacial phosphoric acid has been replaced by a strong solution. A proposition made by Dr. Hirsch that solutions of acids, alkalies, etc., should be of such a strength that equal quantities should represent equal capacity of chemical saturation, appears to have been under consideration, though not found practicable. But the dilute acids, with the exception of dilute acetic and hydrocyanic acids, have been adjusted so as to contain, as nearly as possible, 10 per cent. of absolute acid. In the Pharmacopœa Germanica the number of acids has been reduced by one. The omissions are aromatic acetic, dilute nitric, succinic and valerianic acids and aqua regia; the introductions are formic, pyrogallic, salicylic and liquefied carbolic acids, besides which crude nitric acid has been replaced by fuming nitric acid. The following is a list of the acids, with some details in connection with them:—

Acidum Aceticum, U.S.P., P.G.—The "acidum aceticum," U.S.P., has a sp. gr. at 59° F. of 1·048, and contains 36 per cent of $HC_2H_3O_2$, being therefore slightly stronger than the B.P. acid, which contains 33 per cent. It would appear that having abandoned crude and distilled vinegars, every precaution is now to be taken to secure a pure acetic acid, new tests having been added for iron, copper, calcium, fixed impurities and foreign acids, empyreumatic substances, and organic impurities. The "acidum aceticum," P.G., comes near to the glacial acetic acid, U.S.P., and especially B.P. It is a colourless liquid at 15° C., becoming solid when cooled, and boiling at about 117° C. Its sp. gr. at 15° C. is 1·064, and it contains 96 per cent. of $HC_2H_3O_2$. When 5 c.c. of acid is diluted with 15 c.c. of distilled water and 1 c.c. of permanganate solution (1 in 1000) added the red colour should not disappear within ten minutes, showing absence of empyreumatic bodies, acetone, and formic and sulphurous acids. The other tests are for the presence of mineral acids; but it has been pointed out that since the choice of a 96 per cent. acid will admit an acid that is usually made by distilling sodium acetate with strong sulphuric acid, it would have been as well to have had a test for cacodyl and other arsenical impurities. In the description there occurs the curious phrase: "Liquor . . . . odoris spinose acidi."

Acidum Aceticum Dilutum, U.S.P., P.G.—The U.S.P. "dilute" acetic acid is made by mixing 17 parts of the stronger acid with 83 parts of water. It has a sp. gr. of 1·0083, and contains 6 per cent. of $HC_2H_3O_2$, being stronger than that in the last edition, which resembled the B.P., and contained 4½ per cent. The P.G. "dilute" acid is much stronger; its sp. gr. is 1·041 and it contains 30 per cent. of $HC_2H_3O_2$. The direction for the volumetric test is rather peculiarly worded: "Ad centimetros cubicos quinquaginta Liquoris Kalii hydrici volumetrici saturandos grammata decem sufficiant, id quod triginta Acida acetici in partibus centum respondet." This, whilst it would ensure a preparation containing 30 per cent. of acid, would not, construed strictly, exclude a stronger one. The same form occurs elsewhere.

Acidum Aceticum Glaciale, U.S.P. (new).—Sp. gr., when liquefied and as near as possible to 59° F., 1·056 to 1·058; contains not less than 99 per cent. of $HC_2H_3O_2$. It is said to be a crystalline solid at or below 59° F., whilst the temperature given in the B.P. is 48° F. It may be mentioned, however, that, according to Hager's table, as well as Oudeman's, which is included in the Appendix to the U.S.P. the sp. gr. of 1·065 to 1·066, given in the B.P., would correspond at 15° C. (59° F.) to only about 95½ per cent. of acetic acid ($HC_2H_3O_2$), although 84 per cent. of acetic anhydride ($C_4H_6O_3$), the quantity mentioned in the B.P., would represent 98·82 per cent. The introduction of glacial acetic acid into the U.S.P. became necessary to meet the requirements of the new solution of acetate of iron. As previously mentioned, the "acidum acetum," P.G., is practically a glacial acid.

Acidum Arseniosum, U.S.P.; *Acidum Arsenicosum*, P.G.—In both Pharmacopœias it is described as being completely, but slowly, soluble, in 15 parts of hot water; the U.S.P. adds, also, in 30 to 80 parts of water at 59° F., and moderately in glycerine. The U.S.P., like the B.P., admits the opaque powder form; but the P.G. has only "frusta alba porcellanæ similia vel pellucida," probably because the mass form is more likely to be pure. According to the U.S.P. it should be "odourless and tasteless." The volumetric test in the U.S.P. requires that a solution of 0·247 gram of arsenious acid with 0·5 gram of sodium bicarbonate in boiling water shall decolorize not less than 48·5 c.c. of vol. sol. of iodine and this is said to correspond to at least 97 per cent. of As_2O_3, but it has been pointed out that the quantity of sodium bicarbonate is insufficient. The point of complete volatilization is given at 424·4° F., but in the B.P. it is "not exceeding 400° F." The P.G. guards against the sulphide by requiring that a solution in 10 parts of hot liquor ammoniæ should not be coloured yellow when hydrochloric acid is freely added. Both works perpetuate the somewhat barbarous test for the recognition of arsenious acid by the alliaceous odour evolved when it is thrown upon ignited charcoal.

Acidum Benzoicum, U.S.P., P.G.—Few subjects have occupied a larger share of space in German pharmaceutical literature than this acid, since the publication of Dr. C. Schacht's paper on the permanganate test for its purity (*Pharm. Journ.*, [3], xii., 517). Although there can be little doubt that other kinds than the sublimed have been freely used in Germany, and that this practice has received indirect sanction by the legal price specified in the *Arznei-Taxe*, the P.G. still orders that benzoic acid shall be prepared from benzoin by sublimation. Apparently to secure this the description of the colour of the crystals has been altered from "whitish, eventually yellow," to "yellowish or yellow-brown;" and besides smelling of benzoin it is to have an empyreumatic odour. The solubility in water has been altered from 1 in 200 to 1 in 320. The change as to colour appears to be intended to utilize the propensity of sublimed benzoic acid to become coloured, so as to exclude a "masked" acid prepared by submitting to sublimation a mixture of artificial or precipitated acid and benzoin, such a product being colourless, or at most occasionally yellowish. This coloration, however,—which is due to a small quantity of adherent volatile oil derived from the resin ('Pharmacographia,' 408),—is not an invariable character of sublimed benzoic acid, especially of the different fractions of a sublimation, though there appears to be some difference in opinion as to the relative colour of the fractions. Hager says (*Commentar*, p. 59) that the first four-fifths of the acid subliming from the resin is pure white, and that the yellowish and stronger coloured crystals make their first appearance when the heat has been considerably increased; also that the empyreumatic odour only becomes apparent in the third or fourth fraction. Sometimes, he says, but only seldom, a benzoin occurs that yields little white and more yellowish sublimate. On the other hand, Schneider (*Archiv*, xvii., 893) says that the first sublimation fraction is most richly saturated with volatile oil and therefore yellow and brownish, whilst the portion obtained last is much poorer in volatile oil and appears therefore almost colourless. Possibly the apparent contradiction is explained by the fact that Hager's results were obtained in using a temperature of 140° C. at the commencement of the operation, and afterwards raising it to 170° to 180° C., whilst Schneider maintained the temperature between 150° and 160° C. throughout. But there can be little doubt that the collected product of an entire sublimation from Siam benzoin is coloured. In preparing benzoic acid by the wet process the later crystallizations are darkest. It is upon the presence of this adherent volatile oil in acid sublimed from Siam benzoin, and its reducing action upon potassium permanganate, that the new test in the P.G., which has provoked much criticism, is based. It provides that 0·1 gram of acid dissolved in 5 c.c. of boiling water, to which, after cooling, 16 drops of permanganate solution (1 in 200) has been added, shall be almost colourless at the end of eight hours. Other substances, however, are known capable of answering this test, for instance, vanillin, which has been met with in Siam benzoin ('Pharmacographia,' 409), and as a result of the discussion on the point, the German pharmacist has been recommended to protect himself by subliming in his own laboratory the benzoic acid he requires. It has been pointed out that an impurity of cinnamic acid would contribute to the reducing action, but then the benzoic acid would not answer to the character that when warmed in a test-tube with an equal weight of potassium permanganate and 10 parts of water the odour of bitter almonds must not be evolved. As, however, cinnamic acid would pass over with benzoic acid in the sublimation and cannot afterwards be separated, the necessity for using a benzoin free from that acid has considerably affected the price of Siam benzoin in Germany. On the other hand, turning to the U.S.P., it is found that the crystals are described as "white," nothing is said of an empyreumatic odour, whilst a provision in the 1870 edition that benzoic acid should be prepared by sublimation, and a description of the process, have been omitted from the new edition. But the tests have been increased in number. A solution in pure cold sulphuric acid, when gently warmed, should not turn darker than light brownish, and then when poured into water the benzoic acid should precipitate white and leave the liquid colourless. When introduced with recently ignited and moistened cupric oxide into a non-luminous flame it should not impart a green or bluish-green colour to the flame (chlorobenzoic acid). It should not have an odour like that of bitter almonds or stale urine. Two parts of acid and one part of potassium permanganate, rubbed with a little water in a mortar, should not evolve an odour of bitter almonds (cinnamic acid). The solubilities given are: in water at 59° F., 1 in 500; alcohol at 59°, 1 in 3; boiling water, 1 in 15; boiling alcohol, 1 in 1; ether, 1 in 3; chloroform, 1 in 7; in carbon disulphide, benzol, benzin, and oils, readily soluble; and freely soluble in solutions of potash, soda or ammonia. The crystalline needles are said to be "friable." This is probably a mistake for "flexible."

Acidum Boricum, U.S.P. (new); P.G.—In the U.S.P. the ordinary tests are given to prove the absence of sulphates, chlorides, calcium, lead, copper, iron, etc. Heated in a non-luminous flame the acid should not impart to it a persistent yellow colour. Solubilities: in water at 59° F., 1 in 25; alcohol at 59° F., 1 in 6; boiling water, 1 in 3; boiling alcohol, 1 in 5. The P.G. also provides for the absence of metallic impurities, sulphates and chlorides; the solubilities, too, are similar. Both works state that a solution in spirit, when ignited, burns with a green-margined flame, and the P.G. says the same of a glycerine solution; but it does not point out that in order to ignite the glycerine it should be previously heated to about 160° C. (*Pharm. Journ.*, [3], v., 441).

Acidum Carbolicum, U.S.P., P.G.—Described in the U.S.P. as a product of distillation of coal-tar between 356° and 374° F. (1873, between 300° and 400° F.), and occurring in "colourless, interlaced needle-shaped crystals, sometimes acquiring a pinkish tint, deliquescent on exposure." The crystals are said to melt at 96·8° to 107·6° F., and boil at 357·8° to 366·8° F., the higher melting and the lower boiling points being given as those of pure anhydrous acid. It may be remarked that deliquescence has been attributed to the presence of cresylic acid (*Pharm. Journ.*, [3], v., 661). The odour is said to be slightly aromatic, "resembling creasote." A minute quantity of ferric chloride added to a one per cent. solution of carbolic acid produces a permanent violet-blue colour (with creasote it turns rapidly greenish and brown). One volume of liquefied carbolic acid, containing 5 per cent. of water, forms with 1 volume of glycerine a clear mixture not rendered turbid by 3 volumes of water (absence of creasote and cresylic acid). In the U.S.P. it is stated that the amount of water in carbolic acid may be determined by shaking equal volumes of acid and chloroform together, the water forming a supernatant layer upon standing; but the correctness of this statement has been questioned by Cripps (*Pharm. Journ.*, [3], xiii., 954). The P.G. describes the crystals as "coloris expers vel vix rubicunda." The melting point given covers a wider range than in the U.S.P., being from 35° C. (95° F.) to 44° C. (111·2° F.), whilst the boiling point is from 180° C. (356° F.) to 184° C. (363·2° F.). In the B.P. the boiling point given is 370° F. According to Schorlemmer (*Pharm. Journ.*, [3], v., 739) the boiling point of absolutely pure carbolic acid is 181·5° C. (358·7° F.). Besides the characteristic reaction with ferric chloride the P.G. gives the formation of white flocks of tribromphenol with bromine solution (*Pharm. Journ.*, [3], vi., 821).

Both works give the solubility of pure carbolic acid in water as 1 in 20 at 59° C.

Acidum Carbolicum Crudum, U.S.P., P.G.—Unlike the B.P., the U.S.P. and P.G. both define a crude carbolic acid for disinfecting purposes. In the U.S.P. it is described as a nearly colourless or reddish-brown liquid obtained during the distillation of coal tar, between 338° and 374° F., and containing variable proportions of carbolic and cresylic acids, together with other substances. It should not be soluble in less than 15 parts of water, and the quantity of undissolved impurities present after the crude acid has been shaken with twenty times its volume of warm water and allowed to cool is now limited to 10 per cent. The crude carbolic acid of the P.G. is described as a clear yellowish or yellowish-brown liquid, easily soluble in alcohol and ether, and incompletely and with more difficulty in water. After shaking 10 vols. with 90 vols. of caustic soda solution, sp. gr. 1·079, the liquid or semi-liquid residue should not exceed 1 vol., and the alkaline liquid, when removed and rendered acid with sulphuric acid, should separate a yellowish or yellow-brown oil, giving the reactions of carbolic acid and scarcely soluble in 30 volumes of water.

Acidum Carbolicum Liquefactum, P.G.—This preparation appears to have been introduced as more convenient in dispensing than the crystalline form, which is sometimes troublesome to remove from a bottle. It is made by mixing 100 parts of carbolic acid with 10 parts of water and is described as a clear colourless liquid, completely soluble in 18 parts of water. It is noticeable, however, that the official carbolic acid, which would be used for the preparation, may be "vix rubicunda," and a simple calculation will show that the solubilities given for the two articles do not correspond.

Acidum Chromicum, P.G., U.S.P.—In the U.S.P. a test defining the limit of sulphuric acid has been inserted and from the P.G. a similar test has been omitted. In both works the crystals are described as "deliquescent," and on this account the P.G. allows a solution of the acid in an equal weight of water to be kept ready prepared for use. But according to Hager (*Commentar*, p. 85) the deliquesence of chromic acid crystals is due to contamination with sulphuric acid, and when they are quite free from this impurity they are permanent in the air. A similar solution is official in the Codex. The U.S.P. contains a warning against the danger attending the contact, trituration or warming of this acid with easily oxidizable substances.

Acidum Citricum, U.S.P., P.G.—No process is given in either work; the tests are for the absence of sulphuric, oxalic and tartaric acids, lime, lead and other metals. In the U.S.P. the solubilities given are in water at 59°, 1 in 0·75; in alcohol, 1 in 1; in boiling water or boiling alcohol, 1 in ½; in ether, 1 in 48; nearly insoluble in absolute ether, chloroform, benzol and benzin. When ignited, 0·05 per cent. of ash is allowed, but this must not turn blue when moistened with ammonia, or blacken with sulphide of ammonium (absence of lead, copper and iron). The above solubility in water corresponds with that given in the B.P., but the P.G. gives it at 1 in 0·54. Moreover, whilst in the U.S.P. the acid is said when heated to 100° C. to melt and gradually lose 8·6 per cent. of its water, in the P.G. it is said to liquefy at about 165° C.

Acidum Formicicum, P.G. — A clear colourless liquid, with a pungent (*spinosi*) but not at all empyreumatic odour and very acid taste. The volumetric test with caustic potash solution corresponds to 25 per cent. of CH_2O_2; but the specific gravity is given as 1·060 to 1·063, the lowest of which figures would represent less and the highest more than that quantity. It is required in the preparation of spiritus formicarum. This acid is said to be used in Germany, dissolved in spirit (5 to 20 per cent. solutions), as an external remedy against chronic rheumatism, and doses of from 0·5 to 2·0 grams dissolved in 80 to 100 parts of water are, according to Hager, given as an antiseptic.

Acidum Gallicum, U.S.P.—Process omitted. Solubilities: in water at 59°, 1 in 100; in alcohol, 1 in 4½; in boiling water, 1 in 3; in boiling alcohol, 1 in 1; in absolute ether, 1 in 39; less soluble in chloroform, benzol and benzin. It is distinguished from tannic acid by not precipitating alkaloids, gelatin, albumen, gelatinized starch, etc. Not included in the P.G.

(*To be continued.*)

THE PREPARATION OF PHOSPHORIC ACID BY THE OXIDATION OF PHOSPHORUS WITH ATMOSPHERIC AIR IN THE PRESENCE OF MOISTURE.*

BY W. T. WENZELL, PH.G., M.D.,

Professor of Chemistry in the California College of Pharmacy.

A preliminary paper announcing some experiments and results favourable to the preparation of phosphoric acid by moist oxidation was read at a quarterly meeting of the California Pharmaceutical Society held in July, 1882.

Since then further experiments were made with the view of devising a process by which the principles here involved could be carried out in a practical way and free from danger. That phosphoric acid might be prepared easily and in any quantity by this process was suggested by the following incident:—

A common ointment-jar, containing ½ pound of phosphorus (the sticks were in a vertical position, immersed in water), loosely covered, was kept in a basement, where the temperature usually varies between 58° and 65° F. On taking off the cover, at the expiration of four months, it was noticed that not only two-thirds of the water had evaporated during that time, but that a relative quantity of the phosphorus had also disappeared, the upper ends of the sticks presenting the appearance of being, as it were, smoothly cut to the level of the water. The liquid was not only very acid, but was also very dense, of a somewhat oily consistence.

That phosphoric and phosphorous acids are produced by the oxidation of phosphorus in moist air is certainly not new, but I could not find in the various standard works on chemistry I then consulted that this process had ever been applied or recommended as a method for the production of phosphoric acid. It was only of late, and after the completion of my experiments, that I happened to find, in Mohr's 'Commentary to the Prussian Pharmacopœia for 1850,' mention that phosphoric acid might be made by a process of slow oxidation in air. F. Mohr recommended to have a stick of phosphorus put into a glass tube narrowed at one end; to have a number of such tubes laid into a glass or porcelain funnel, the end of which (the funnel) dipping into a flask containing water. The phosphorus oxidized, as was stated, very slowly, emitting a luminous vapour, which gave out an odour resembling that usually observed when sparks from a powerful electrical machine are passed through air (ozone). Mohr admitted that it was rather slow as to results. He mentions, also, a process recommended by Doebereiner,

* Read at the Fourth Session of the American Pharmaceutical Association. From the 'Proceedings,' 1882.

which directs pounded glass to be put into the bottom of a flat porcelain dish to the depth of 1 inch, to cover the pounded glass nearly with water, and lay thereon any suitable number of phosphorus sticks, taking care to prevent their touching each other; the whole to be covered with a bell-glass. Oxidation by this process is stated to be more rapid than that of Mohr's.

That neither of the two methods have found favour is no doubt owing to their impracticability and the highly probable risk of dangerous combustion, as no provision was recommended to regulate the supply of air.

I have found that a simple arrangement for the aerial oxidation is had in an ordinary infusion jar. A pint jar, holding 7 fluid ounces up to the perforated diaphragm, will answer for 360 grains of phosphorus (the officinal quantity); a quart jar, holding 10 fluid ounces to the diaphragm, will be suitable for 720 grains. The phosphorus in the form of sticks is laid upon the diaphragm, a sufficient quantity of water is poured into the jar to immerse the sticks to about half their diameter, and the lip of the jar closed by pasting paper over the mouth or inserting a rubber cork. The top of the jar having previously been ground true and smooth was then covered with a porous disk of plaster of paris, about one-eighth of an inch thick.

The jar, having been thus prepared, oxidation of the phosphorus will commence at once, and will continue regularly, requiring no attention until after the expiration of one week. At this time the phosphorus will be found to have disappeared to the surface of the water. It will now be necessary to pour off a portion of the acid liquid in order to expose the lower half of the phosphorus to the influence of moist oxidation, taking care to replace the porous disk. During the course of the second week the acid fluid may require to be poured off more than once, owing to an increase in its volume.

To prepare a larger quantity of the acid, a leaden tray was provided and so constructed as to make the process more automatic in its effects. This arrangement is capable of oxidizing 8 ounces of phosphorus, measured in the clear, 9 inches in length, 5 inches in width and 3 inches in depth. On the inner sides, about $1\frac{1}{2}$ inch from the bottom, a narrow shelf gave support to a grating of sheet lead, having eight narrow slits cut transversely, on which the phosphorus sticks were laid with about $\frac{1}{2}$ inch space between. The upper edge of the tray was smoothed to fit a porous cover of plaster of paris, having a thickness of $\frac{1}{2}$ inch. Into one of the end sides of the apparatus, as near as possible to the bottom, a round hole was provided, and a rubber cork inserted, through which a glass tube was passed bent at a right angle, the bent limb being just of a length to reach accurately the leaden grating, when the latter was placed *in situ* within the tray. Attached to the limb of the tube, and parallel to it, another glass tube was cemented, the upper end on a level with the limb of the bent tube, and extending about $\frac{1}{2}$ inch below the bend of the other tube. The apparatus being thus arranged, the bent end of the tube was stopped with a well-fitting plug, the phosphorus laid upon the slits of the grating, and a sufficiency of water poured into the tray to half immerse the sticks, and the apparatus finally covered with the plaster of paris tile, which should fit the top of the tray sufficiently close as not to allow any fumes to escape.

In about a week, the cover may be lifted, when, if the phosphorus is nearly, or entirely reduced to the level of the liquid, the plug may be removed, and the acid fluid allowed to drain into a suitable receiver, without changing the position of the apparatus. Then replace the porous tile, and if the upper extremity of the bent tube has been adjusted so that the level of the liquid in the tray will just about touch the lower segments of the phosphorus sticks, the final oxidation will be, from this on, entirely automatic, and no further attention is necessary until the phosphorus is consumed. For, from this stage of the process, on to the end, there will be a continual augmentation in volume of the acid fluid. It is by means of the bent tube that the surplus is drained off and thus the acid liquid in the tray kept at the same level. When the process is completed, the acid solution may be drawn off by turning the bent limb of the glass tube down.

The leaden tray was used only on an experimental basis, and is not to be recommended, inasmuch as a certain amount of lead phosphate is unavoidably formed, which is sufficiently soluble in the acid fluid to contaminate it. An apparatus made of white pottery, glazed to resist acids, is no doubt the best. A tray and grating made of gutta-percha may possibly answer.

The products of the moist aerial oxidation of phosphorus are known as follows:—

Phosphoric acid, H_3PO_4.
Phosphorous acid, H_3PO_3.
Ozone, O_3.
Hydrogen peroxide, H_2O_2.
Ammonium nitrate, NH_4NO_3.

Phosphoric acid is produced by far in the largest proportion; next in importance as to quantity will be found phosphorous acid; then ozone and hydrogen peroxide are formed, according to the elaborate investigations of Professor Leeds, in equal molecular proportions. Ammonium nitrate, a concomitant of this process, is produced in small quantities.

During the oxidization of phosphorus in the presence of moisture, a white vapour is always given off. This mist, or white cloud, was at one time supposed to consist of a mixture of the vapours from phosphorus and phosphorous acid. Schoenbein, the discoverer of ozone, assumed that the vapour consisted of monatomic oxygen, or antozone, as he called it. It was only of late that its true nature had been ascertained and demonstrated by the classical researches of von Babo, and Nasse and Engler, who furnished conclusive proof that the antozone of Schoenbein is nothing more than hydrogen peroxide, in a state of vesicular suspension; a condition resembling a mist only that it is more durable, and will continue to exist in this state for some time, even after the vapour of water, with which it is associated, has been completely removed.

The following is the probable rationale of this process of oxidization from the *Journal of the American Chemical Society*, vol. iii., p. 6, "On the Ozonization of Air by Moist Phosphorus," by Professor Albert R. Leeds.

(1.) $P_4+O_{14}=P_2O_5+P_2O_3+2O_2+O+O$.
(2.) $O_2+O=O_3$.
(3.) $H_2O+O=H_2O_2$.
(4.) $N_2+2H_2O+O=NH_4NO_3$.

On viewing the above equations it will be seen that by this method of oxidation ozone and hydrogen peroxide are important products; that they are formed, as it appears, simultaneously, and independent of each other. Of this there can be no question, since it has been shown that ozone is not capable of changing the water molecule into hydrogen peroxide. The only sufficiently assignable cause of the formation of these two substances can be found on theoretical grounds, in the quantivalence of the respective phosphorus and oxygen atoms. It necessitates the splitting of the diatomic or ordinary oxygen molecules, in order to supply the phosphorus atoms with the uneven number of oxygen atoms to form phosphoric and phosphorous oxides. It is hence easily conceived that monatomic oxygen, or oxygen at the moment of its liberation from the ordinary oxygen molecule, would become active oxygen, and as such would be capable of oxidizing an oxygen molecule to ozone, a water molecule into hydrogen peroxide, and finally a nitrogen molecule in the presence of water to ammonium nitrate. The porous covering of our apparatus not only allows the gradual admission of atmospheric oxygen to the interior, but it also permits the dialysation of ozone from hydrogen peroxide. The former is given off by diffusion through the porous septum into the atmosphere, whilst the latter is retained within, dissolved by the acid fluid, and there either serves to oxidize a part of the phosphorous acid into phosphoric, or takes a part in the direct oxidation.

That hydrogen peroxide is absorbed and present in the acid solution is demonstrated by shaking together a portion of it with anhydrous ether, and a drop of a solution of chromic acid, when the ether will at once acquire a blue colour from the perchromic acid formed.

That ozone is given off from the porous covering freely and abundantly, may be shown by its peculiar odour and the colour reaction upon a slightly moistened ozone test-paper (Schoenbein's). As has been stated, the acid solution is composed of a variable mixture of phosphoric and phosphorous acids; but it generally contains also in addition a certain quantity of arsenic, which, in order to make a correctly pharmaceutical product, will require to be removed; and, further, the phosphorous acid should be converted into phosphoric acid. To effect the former, the acid solution is evaporated in a Berlin or Meissen dish, until a thermometer placed in it will indicate a temperature of 160° C. At this temperature the acid liquid will become turbid, and deposits the arsenic in the metallic state as a brownish-black substance, and if this heat is maintained a short time, all of the existing arsenic in the liquid will be completely precipitated, the supernatant becoming clear and colourless.

That arsenic may separate from a heated phosphoric acid solution has been shown by E. A. Schreck, in a paper on "Dilute Phosphoric Acid," published in the 'Proceedings' of the California Pharmaceutical Society for 1880.

He found a separation of arsenic to occur when the temperature was inadvertently allowed to go far above 400° F. (204° C.), a point at which the acid was found to act strongly on the dish. The removal of arsenic at 160° C. (320° F.) is complete, and it is not unimportant to consider that neither this temperature nor the concentration of the acid is sufficient to affect Berlin or Meissen ware materially. (The specific gravity of the acid at this degree of concentration is 1·75.) If, however, the heat be allowed to reach 170° C., and beyond it, the phosphorous acid will resolve itself into phosphoric acid and spontaneously inflammable hydrogen phosphide, which, as it is given off, will burn vividly with a snapping noise.

$$4\,H_3PO_3 = 3\,H_3PO_4 + H_3P.$$

The arsenic probably exists in the acid liquid as arsenic acid, as it is well known that hydrogen peroxide is capable of oxidizing arsenious acid into arsenic. The reduction of arsenic acid to metallic arsenic may be formulated to the following equation:—

$$5\,H_3PO_3 + 2\,H_3AsO_4 = 5\,H_3PO_4 + 3\,H_2O + As_2.$$

The acid solution is next to be diluted and filtered preparatory to the oxidation of the phosphorous acid into phosphoric acid. The filtrate is evaporated until the thermometer indicates 120° to 130° C. At this temperature the oxidation is easily effected by means of nitric acid, the usual nitrous vapours being given off. The amount of nitric acid specific gravity 1·38 required for the completion of an acid solution obtained from 360 grains of phosphorus varies from 2 to 5 drachms. (To oxidize the same quantity of phosphorus requires, by the officinal process, 5 troy ounces of acid of specific gravity 1·40.) By adding the nitric acid until nitrous vapours cease to be given off, an excess of the acid will unavoidably remain, and will require prolonged heating and a high temperature until it is all dissipated. In order to avoid this trouble, in some part of the process, a slight change was made in the mode of procedure by reserving a portion of the acid fluid for the purpose of getting rid of the excess of nitric acid, and thus dispense with the final heating. I have found that by reserving about one-tenth of the solution, an amount usually in excess of what is actually required, the desired end is easily accomplished. The oxidation is conducted in the usual way, the nitric acid being added in small portions at a time until the liquid acquires a yellowish tinge and the effervescence from the escape of nitrous vapour has almost ceased. The reserved portion is now to be added gradually, when, in due time, a point will be reached when the yellow colour of the liquid is replaced by a bluish-green, which, gradually fading, ultimately becomes colourless. Should any of the reserved liquid be left it may be added in small portions, each of which may also be oxidized by the cautious addition of a few drops of nitric acid. A valuable guide for determining the end reaction will also be found in noticing the gas bubbles as they form and break on the surface. If they contain coloured nitrous vapours, more of the reserved liquid should be added; and if, on the other hand, the bubbles are filled with a colourless gas (nitrous oxide), the oxidation may be assumed as practically completed. A minimum excess of phosphorous acid is rather desirable, as it insures the absence of nitric acid, and it will become, in time, converted into phosphoric acid by absorption of oxygen from the atmosphere.

The phosphorous acid may also be oxidized in a flask of from eight to ten times the volume of the acid fluid. This method has the advantage that but a very small quantity of nitrous fumes will escape during the process if the flask is sufficiently large, the nitric peroxide being utilized in the oxidation. This process will hence require a still smaller quantity of nitric acid. The operation is also accomplished with less annoyance to the operator on account of the small amount of nitrous fumes given off into the air from the flask. The reactions taking place within the flask may be formulated as follows:—

(1.) $2\,H_3PO_3 + 2\,HNO_3 = 2\,H_3PO_4 + H_2O + N_2O_2.$
(2.) $N_2O_2 + O = N_2O_4.$
(3.) $N_2O_4 + H_2O = HNO_3 + HNO_2.$
(4.) $\begin{cases} 2\,HNO_3 + 2\,H_3PO_3 = 2\,H_3PO_4 + H_2O + N_2O_2. \\ 2\,HNO_2 + 2\,H_3PO_3 = 2\,H_3PO_4 + H_2O + N_2O. \end{cases}$

The liberated nitric oxide, a product of the first reaction, on coming in contact with atmospheric air which enters the open flask, is there converted into nitric peroxide, and, on being dissolved in the aqueous vapour filling the flask, gives rise to the production of nitric and nitrous acid as shown in third reaction. These acid vapours, condensing on the cooler sides of the flask, flow back into the liquid, causing further oxidation, nitric oxide being again disengaged, as exemplified in the fourth reactions, the final product being nitrous oxide, which escapes. Unquestionably nitric peroxide acts here in a nearly similar manner in promoting oxidation as it does in the conversion of sulphurous oxide into sulphuric in the manufacture of sulphuric acid, nitrogen dioxide being simply a carrier of oxygen.

In using the flask process care should be taken to adjust the amount of nitric acid at a time to the size of the flask, or the amount of nitrous fumes produced should not be formed in such quantity as to cause any considerable escape. Again, no further addition of nitric acid should be made until the nitric peroxide is first absorbed and the interior of the flask above the acid liquid rendered nearly colourless. The mode of conducting the final oxidation by means of a reserved portion may also be used here, and also the manner of ascertaining the end reaction. Should, however, any doubt be entertained as to the absence of nitric acid, its presence is readily detected by moistening a fragment of crystallized ferrous sulphate with a little of the acid fluid by means of a glass rod, producing the well-known dark brown coloration.

This method is, as a matter of course, somewhat tedious, particularly if the quantity of acid to be made is considerable. Its advantages can only be said to outweigh the trouble if the officinal quantity or its double is to be made and no conveniences are to be had for carrying off the nitrous vapours.

OPIUM AND OPIUM SMOKING.*

BY HUGH MCCALLUM.

The morality of the opium trade has been discussed at great length and with much heat, especially by those who denounce the traffic. The effects of indulgence in the opium pipe have been, and are still, represented to be of the most pernicious and degrading character. Neither of these questions has been discussed in the calm impartial manner necessary to ascertain the real facts. Far more attention has been given by the disputants to bringing forward telling points in support of preconceived ideas, than in searching out the truth. In this paper it is not intended to deal with either subject in a controversial spirit and any remarks which may appear to tend in that direction are purely incidental.

It is generally assumed and frequently asserted, that the effects of opium smoking are practically the same as that of opium eating and opium drinking. It is on this ground that most of the denunciations of the opium trade and of opium smoking are based. Nine-tenths of those who pay any attention to the opium question are imbued with this idea. The writer, who had some technical knowledge of the medicinal and chemical properties of opium, held this opinion previous to his arrival in China and for some time afterwards. If it can be shown that this view is erroneous, then all the numerous arguments based thereon are worthless. In the following remarks, it is hoped that it is conclusively proved that the effects of opium eating and opium smoking are by no means analogous, but that they are altogether different.

Sir George Birdwood states, that from personal experience and observation, he can testify that opium smoking is perfectly harmless. He invites unbelievers to try the experiment on themselves, and it is quite certain, whoever does so will become, in a great measure, a convert to his dogma. Sir George Birdwood also points out the difference between eating opium and smoking opium, maintaining that none of the active principles of opium are volatilizable; but beyond quoting Sir Robert Christison, he does not appear to have brought forward any evidence in support of this contention.

In dealing with the subject, the first thing to be done, is to ascertain what are the constituents of opium, and to which of them its physiological activity is due. The following may be taken as representing the *general* composition of opium.

	Per cent.
Morphine	4 to 15
Narcotine	2 to 8
Codeine, Narceine, Thebaine, Papavereine	½ to 2
Meconin	under 1
Meconic acid	3 to 8
Peculiar resin and caoutchouc	5 to 10
Fat	1 to 4
Gum and soluble humoid acid matters	40 to 56
Insoluble matter and mucus	18 to 20
Ash	3 to 8
Water	8 to 30

Of the above substances morphine is by far the most important. East Indian opium is remarkable for the low percentage of morphine it contains, and it is noteworthy that this is the variety of opium which is preferred before all others by opium smokers. Before opium is ready for smoking it undergoes an elaborate preparation, by which a considerable portion of the narcotine, caoutchouc, fat, and resin, together with all the insoluble matters and mucus, are removed. The method of preparation has a destructive action on the alkaloids (morphine, etc.) present in the opium. Anyone who is at all conversant with organic substances will at once recognize that the prolonged boiling, evaporating and baking over a naked fire, in a metal vessel, to which the opium is subjected, must necessarily have a degrading action on its alkaloidal constituents.

Referring to the general composition of opium, the only substances remaining in the finished extract which are capable of producing well-marked physiological action, are morphine, codeine and narceine. All are hypnotics and appear to differ only in their degree of potency. The other substances are either inert in ordinary doses or are present in too small quantity to have any appreciable effect. In the pure state, with very great care, it is possible to volatilize morphine unchanged. That these can take place, even in infinitesimal quantity, during the ordinary smoking of a pipe of opium is highly improbable. Even supposing it does happen occasionally it can only be by the merest chance. Admitting that what is improbable does take place, and that an infinitesimal quantity of morphine is volatilized unchanged, in every pipe of opium which is smoked, it would again assume the solid form and be deposited in the stem of the pipe, long before it reached the smoker's mouth. Codeine and narceine give no sublimate.

Dr. Thudichum in the 'Annals of Chemical Medicine,' part v., of vol. ii., states that he knew from the experiments of Descharmes and Bénard that morphine volatilized and existed in opium smoke unchanged. On these data he applies it as a soothing remedy to nervous patients, and apparently with considerable success. It is well, however, to remark that when tried on himself it had no appreciable effect. It is also worthy of note, that neither the patients nor himself make any remark as to the smoke having a bitter taste. On the contrary, he implies that it is mild and aromatic. This is the general opinion regarding the taste of opium smoke, when drawn through an opium pipe; and from repeated personal experiments the writer can confirm this opinion. Now morphine, even in minute quantity, has a distinctly bitter taste and if it existed in the smoke, it is only reasonable to suppose that the taste would have been observed and noted. It is not likely anyone will advance the theory that a change in the physical condition of morphine, is, of itself, sufficient to destroy the bitter taste. The non-bitterness of opium smoke is a point of considerable importance, but it does not appear to have attracted much attention.

Doubtless Messrs. Descharmes and Bénard found traces of morphine in opium smoke, but it is hardly probable that it was after the smoke had passed through a 16 or 17-inch condensing tube. The stem of most opium pipes is considerably over a foot in length, and this stem is practically a condenser, the temperature of which never greatly exceeds that of the surrounding atmosphere. At temperatures four or five times higher than that of the hottest part of the tropics, morphine is a fixed solid. This alone is sufficient to prove the improbability of morphine being found in the opium smoke issuing from the mouthpiece of an opium pipe.

In Brereton's 'Truth about Opium,' 1st edit., p. 245, the following quotation from a letter by Professor Attfield, F.R.S., is given:—"A substance only maintained in vapour at high temperatures when alone may be carried a considerable distance in a current of quite cool smoke." Quite so. However, the learned Professor is not the man to assert,—without first proving it by experiment,—that morphine will volatilize, and pass in a state of vapour through a condensing tube more than a foot long, the temperature of which, at the highest estimate, is not more than 40° C. So far as is known no such experiment has been made. He further states "active vegetable principles such as those of opium, on being heated, yield vapours having, in most cases, the chief properties of the original principle." That is so, as regards chemical and physical properties, but the Professor does not add that they will be capable of producing similar effects on the human system. To prove

* From the *China Review.*

that this may be far from being the case let us take morphine. The chemical formula for morphine is $C_{17}H_{19}NO_3$, by the action of a strong acid, remove a molecule of water and apomorphine, $C_{17}H_{17}NO_2$, is formed. Here there is no great apparent change in the chemical constitution, but the physiological action of the two substances is totally different. Morphine is a powerful and certain narcotic. Apomorphine is a very powerful and violent emetic. It is very evident, that until the physiological effects of the vapours arising from heated morphine have been properly and scientifically tested, it is mere speculation to regard them as having a similar action to morphine.

It has not as yet been found practicable to take, with any approximation to accuracy, the temperature at which the prepared opium is smoked, but it would appear to be at a higher temperature than that at which the opium alkaloids are decomposed. Should this be proved to be the case, it will be of itself sufficient to show that none of the active constituents of opium exist in the smoke in the same condition as they do in opium.

It appears perfectly clear from the general composition of opium and the method of manufacturing the extract, that morphine, codeine and narceine are the only bodies of any importance.

Codeine and narceine give no sublimate.

It has been shown that it is almost if not quite impossible that morphine can exist, even in infinitesimal quantities, in opium smoke which has passed through an opium pipe.

The opium smoke does not possess the well-marked bitterness of morphine.

The variety of opium most affected by smokers is characterized by the small percentage of morphine which it contains.

The method of manufacturing smoking extract has a destructive action on morphine.

So far as is known, no authentic case of acute poisoning from opium smoking has been recorded.

It is well known that many European gentlemen have smoked comparatively large quantities at one sitting, and for the first time, without experiencing any marked sensations.

During nearly a four years' residence in Hongkong, considerable attention being given to the subject, not a single case of narcotism from indulgence in the opium pipe has been observed.

A consideration of all these points clearly demonstrates that whatever the effects of opium smoking may be, they are certainly not the same as those produced by opium eating, nor do they appear to be due to the same active principle, namely, morphine.

It may be urged, that although morphine does not act as morphine on the opium smoker, yet the product or products of its decomposition by heat are the active agents. About two years ago, some experiments were made bearing on this point. The results were somewhat startling. They are not put forward as conclusive evidence, but simply as being corroborative of the idea that morphine is not the active agent which gives pleasure to the opium smoker. Specimens of prepared opium containing widely different amounts of morphine were submitted to a Chinese expert, who was connected with a Hongkong opium firm, for his opinion as to their quality. At the same time, duplicate specimens were given to an old opium smoker for the same purpose. The first series of samples were as follows:—

No. 1. Ordinary prepared opium from Hongkong Opium Farm.
No. 2. Prepared opium *minus* morphine.
No. 3. No. 1, with 10 per cent. morphine added.
No. 4. No. 1, with 20 per cent. morphine added.

The opium expert reported as follows:—

"No. 1 is fairly good, is a mixture of Bengal opium and omething else.

"No. 2 is black and coarse, smell fairly good; is not opium.

"No. 3 is coarse, but can be smoked, contains opium with some other mixture. It is not so good as No. 1.

"No. 4 is very coarse and black, burns like charcoal, contains no opium."

The old opium smoker gave the following as his opinion of the same specimens:—

"No. 1. Good.
"No. 2. Not very good.
"No. 3. Same as No. 1.
"No. 4. Fairly good, but not so good as 1 and 3."

A second series of specimens was submitted with a very similar result. They were as follows:—

No. 1. Opium Farm prepared opium which by assay contained 7 per cent. morphine.
No. 2. No. 1, with 15 per cent. morphine added.
No. 3. No. 1, with 25 per cent. of morphine added.
No. 4. Prepared opium *minus* morphine.

The opium expert gave the following report:—

"No. 1. The appearance is coarse, and when burned it becomes black and hard. It is Bengal drug but not pure. It is mixed with some other stuff and has no taste.

"No. 2. Burns very quick and has no taste or smell of opium at all. Colour red and coarse, when burned gives out plenty of smoke, and leaves simply ash instead of opium to smoke.

"No. 3. Just like No. 2, only a shade better.

"No. 4. When applied to the lamp burns just like opium but in a moment burns quite black, and the dross leaves a bad smell. When burning gives out strong smoke."

The old opium smoker gave the following laconic report:—

"No. 1. Very good.
"No. 2. Same as No. 1.
"No. 3. Not good.
"No. 4. Same as No. 1."

The prepared opium *minus* morphine was made from Patna opium having as little as possible of the other opium constituents removed with the morphine. The specimens were submitted without any remark beyond desiring an opinion as to quality.

It will be observed that the Chinese expert bases his opinion on the physical appearance of the extract; its behaviour in the flame of the lamp and its smell; not on its effect when smoked. The old opium smoker apparently judged of its quality in a somewhat similar manner, but as he actually smoked a considerable quantity of each, his opinion is considered of most value. By request, he got some of his friends to try No. 4, in the second series, and they agreed with him that it was good. On one occasion, in about twelve hours, he smoked a quantity of opium (to which morphine had been added) equal to at least twenty grains of morphine.

We have an opium expert,—a man whose occupation is to judge of the quality of opium for smoking purposes,—gravely asserting that the Hongkong Farmer's best quality of "prepared opium," containing 7 per cent. of morphine is not good. Not only that, but he condemns the same opium altogether when it contains 15 and 25 per cent. of *added* morphine, and states it is not opium at all. At the same time, opium practically containing no morphine receives only qualified condemnation. The old opium smoker does not recognize the same differences as the expert. He classes prepared opium, containing 7 per cent of morphine, the same opium with 15 per cent. of morphine added to it, and an opium practically free from morphine, together, all as being equally good. An opium containing 25 per cent. of added morphine is stated not to be good. Such statements could never have been made had these men based their judgment on the well-known effects produced by opium and morphine when eaten. Had anyone dared no make a similar series of experiments on opium eaters, there cannot be the shadow of a doubt but the experimenter would have made the acquaintance of the coroner's court, and been indicted for manslaughter. Although these facts show that morphine has little, if anything, to do with the pleasure of opium smokers, it cannot be denied that they appear to derive much pleasure and consolation from their pipe. Whence the pleasure? What gives rise to it? What are the temporary and permanent effects caused by smoking opium? These are questions that have not yet been satisfactorily answered, yet they ought to be, and in a scientific manner. Until this is done, the Anti-Opium Society and its supporters are not justified in branding the opium trade with infamy, or the lovers of a pipe of opium as degraded beings.

THE ACTION OF CERTAIN DRUGS ON THE SENSITIVE PLANT, MIMOSA PUDICA.*

BY A. S. RAUSCHENBERG, PH.G.

The old authors have from time to time used the term "sleep of plants" to designate the peculiar nocturnal position assumed by most compound leaves. Ever since the days of Linnæus, we find recorded investigations of this phenomenon.

In Curtis's 'Lectures on Botany,'† we find a very interesting discourse on the relation of the movements of plants and animals.

Ducrochet‡ endeavoured to show that the motion of the mimosa is the effect of galvanic agency.

MM. Bert and Blondean (1868) experimented on the plant with galvanism.

Mr. C. Mackenzie has shown that the movements of the leaves have their origin in the nodules situated at the articulation of leaflets with the petiole and of the petiole with the stem.

Of more recent date, we have the well-known work by Darwin, 'The Power of Movement in Plants,' in which he investigates the so-called "sleep of plants."

He also shows that leaves compelled to remain horizontally at night suffer more from radiation than those allowed to assume the vertical position; it makes no difference whether the apex, the base, or one of the lateral edges is directed to the zenith.

This position which the leaves occupy at night shows that the benefit derived therefrom is the protection of their upper surfaces from radiation and the mutual protection of all the parts from the cold by being closely imbricated.

If with *Mimosa pudica* the opposite leaflets would simply move upwards, their upper surfaces only would come in contact and be protected; but, as it is, they move towards the apex, and they thereby become imbricated and protect one another as well as the petioles.

He also shows that many plants will not "sleep" unless they have been well illuminated during the day; this proves that it is not the decrease of light in the evening, but the contrast between the amount at this hour and during the early part of the day, which excites the leaves to modify the ordinary mode of circumnutation.

Brücke has shown that the movement caused by irritation results from a different state of turgescence in the cells from that which results during sleep.

Professor Marcet performed experiments upon the plant with chloroform and ether.

These experiments were repeated and verified by Dr. Porcher, who states that the tinctures of opium, capsicum and camphor, and morphia and tartarized antimony, produced no effect, while chloroform and ether were the only drugs which caused a contraction of the leaves. He also states that "a drop of oil of aniseed, placed on a leaf-stalk, seemed to have the effect of arresting the transit of any influence beyond it."

Other authors have experimented on the various species of sensitive plants, but none mentions having used other agents besides chloroform, ether, oil of aniseed, tartarized antimony, morphia, liquor potassæ, sulphuric and nitric acids, and a few tinctures of active drugs.

In the experiments mentioned below, it will be seen that I have used a larger number of drugs, and in several instances procured quite different results from those mentioned by these various authors.

During my investigation, the plants were kept in a conservatory at the temperature of 80° F. (26·6° C.). A separate plant was used for each experiment, which was performed by applying a drop of the liquid drug directly to one of the pinnæ.

The leaves of *Mimosa pudica* possess a remarkable degree of sensibility or irritability. When roughly touched, the plant suddenly contracts its leaflets, and applies them one over the other upon the secondary petiole.

If more strongly irritated, the secondary petioles are also bent forward, and approach each other, while the main petiole sinks at the articulation with the stem.

These motions are also produced by anæsthetics and other drugs, but are prevented by low temperatures.

As an illustration, I will describe the effect of chloroform.

When this substance is applied to the apex of the lateral pinna, the opposite leaflets, with the points forward, approach each other seriatim, and fold one over the other, thereby protecting the upper surfaces.

Next, the main petiole sinks by the bending of the articulation with the stem.

After this, the leaflets of the remaining three pinnæ contract successively as the sympathy passes from the articulation to the apices.

At the same time, the four pinnæ slowly approach each other until the whole leaf forms a compact bundle.

After about three or five minutes, the next lower leaf on the main stem of the plant sinks by the articulation of the primary petiole, and then the leaflets of the four pinnæ contract as the sympathy passes to the apices. Four or five leaves below the one to which the drug was applied are affected in the same manner; in this respect, my results do not coincide with those of Dr. Porcher.

The following drugs have the same effect as that produced by chloroform:—

1st. Acetic, formic, ethylic, hydriodic, hydrobromic, hydrochloric and methylic ethers, nitrite of amyl, carbon disulphide, ethylic and methylic alcohols.

2nd. Sulphuric, nitric, nitro-hydrochloric, hydrobromic, hydrofluoric, phosphoric, sulphurous, chromic, carbolic, acetic, monochlor-acetic, lactic and oxalic acids; iodine, chlorine, and bromine waters; creasote and essential oils, as anise, mustard, etc.

Those in the first list do not cause the leaflets to become so densely imbricated as those in the second list.

Many substances have an effect which can only be attributed to the alcoholic solvent, as a glance at the lower list will show. The following tinctures give the same results as alcohol, namely, aconite, belladonna, opium, nux vomica, hyoscyamus, digitalis, capsicum, conium, and veratrum.

Certain other physiologically powerful substances have no effect at all, viz., aconitine, atropine, morphine, strychnine, hyoscyamine, digitaline (so-called), duboisine, apomorphine, curare, bichloride of mercury, and tartarized antimony.

I found that *dilute hydrocyanic acid* and *tincture of cantharides* produce peculiar results.

If the former be applied to the apex of a leaflet, it will cause no irritation, but when applied to the articulations of the leaflets with the pinna, it causes a rapid contraction, the same as chloroform.

Five or ten minutes after they have re-expanded, they

* From a thesis presented to the College of Pharmacy of the City of New York, March, 1883. Reprinted from *New Remedies*, April, 1883.

† Vol. i., sec. 2, 1805.

‡ 'Sur la Motilité,' etc., Paris, 1824.

begin to contract in series formed by six or eight opposite leaflets; but when about half closed, they are arrested, and then slowly assume their normal position.

When tincture of cantharides is applied to the articulation of the two opposite leaflets situated in the centre of a pinna, it causes the leaflets below this point to contract in series as above described, and with a pause before each series begins to move.

It never causes all the leaflets of a pinna to contract at once; but it always proceeds downwards, that is, towards the articulation with the main petiole.

Those leaflets which have not closed may be made to do so by touching the tincture to their articulations.

About ten minutes after they have again expanded, they begin to contract in series as before, until all the previously affected ones are imbricated.

This remarkable phenomenon I found to be produced only by the two above-named substances.

Oil of anise placed in several spots on the pinnæ does not prevent the transmission of extraneous irritation beyond that point to which it is applied.

I have performed experiments similar to those of Mr. C. Mackenzie, and with the same results as he procured, as the following will show.

By removing the lower half of the node situated at the articulation of the petiole with the stem by means of a longitudinal section, the petiole will remain depressed, it having lost the power of elevating itself. If the superior half be removed, the petiole will remain constantly elevated, it having lost the power of depressing itself.

These facts show that the motions of the petiole depend on the alternate turgescence of the upper and lower half of the pulvinus situated at the point of articulation, and that, consequently, contraction is not the principle of these movements.

The following experiments are in accordance with those of M. Ducrochet; they prove that the interior movement is propagated by the ligneous fibres and vessels.

The irritation is transmitted equally well, even if a ring of bark be removed and nothing remains to communicate between the divided portions of bark except the ligneous fibres; it is also transmitted when the parts are connected by a fibre of bark, and also when the pith is the only connecting link.

But when the communication exists only by the cortical parenchyma, the irritation is not transmitted.

Transit is more rapid in the petioles than in the stem.

The experiments with electricity are those suggested by the results of M. Blondean.

A plant was acted on by a galvanic current for about five minutes, when it became contracted, but soon again expanded its leaflets. Another operated on for ten, and still another for fifteen minutes, became contracted, but again expanded.

When it was operated on for thirty minutes, it did not re-expand its leaflets.

An etherized plant was not affected by the current.

If a plant which has been kept in an obscure place be suddenly exposed to the sun, the leaflets will contract; in this case, the sun-light seems to act as if it were a touch. This is called the "Diurnal Sleep of Plants," or "Paraheliotropism," which, according to Professor Wiesner,* seems to have for its object the protection of the chlorophyll, which is destroyed by action of concentrated sun-light in contact with oxygen.

It will be seen from what has been stated so far that I have experimented with a larger number of drugs than previous observers, and that I have classified them as substances which have the same effect as chloroform, and as such which have an effect merely produced by the alcoholic solvents, as is shown by the fact that the active principles of the same drugs produce no effect whatever upon the plant.

My experiments differ from those of Dr. Porcher by the irritation being transmitted down the main stem of the plant, until four or five leaves have contracted, and by the oil of anise failing to arrest the transit of influence beyond the spot to which it is applied.

Like Mr. Mackenzie, I find by dissection of the node situated at the base of the petiole that the motions depend on the alternate turgescence of the upper and lower half of this organ.

The results, similar to those of M. Ducrochet, prove that the interior movement is transmitted by the ligneous fibres and vessels.

The experiments with galvanism show that etherized plants are not affected by a current which would destroy them under other circumstances.

But the principal fact first shown by my experiments is, that, after the plant has recovered from the primary effect of hydrocyanic acid or tincture of cantharides, there is a secondary effect produced, similar in character to the first, after which the leaves re-expand, assuming their natural position.

* 'Die natürlichen Einrichtungen zum Schutze des Chlorophylls,' 1876.

GERMS AND EPIDEMICS.*

BY JOHN S. BILLINGS.

In these days of the diffusion of knowledge, which is sometimes spread not only wide but thin, everyone is more or less familiar with the phrases "disease germs," "the germs of small-pox," "the malarial germ," etc., although some who speak of these in quite a familiar and patronizing way might, perhaps, find it rather difficult to state clearly the conception which they have as to the nature of these so-called germs, or as to the manner in which they produce disease. Very possibly, indeed, some may be inclined to consider these germs as being rather imaginary entities than actually observed things, an ingenious hypothesis rather than a demonstrated fact. It is the object of this lecture to state what we really do know at the present time about this subject, and to indicate the bearings of this knowledge in relation to epidemics.

That certain prevalent diseases are due to the entrance of minute living organisms from the air or water into the lungs or stomach, whence they work their way into the blood, is a very old idea. For example, Terentius Varro, a Latin author of the first century before Christ, says in his work 'De re rusticâ,' that marshy places are to be avoided because in them there grow certain minute animals which cannot be perceived by the eye, and which being carried in the air enter the body through the mouth and nostrils and produce very serious diseases. Varro states this as if it were an old and familiar idea, and it is quoted approvingly by subsequent writers, but no attempt seems to have been made to give the theory with precision until after the introduction of the microscope and the publication of the discoveries of Leuwenhoek. You can, perhaps, imagine the astonishment and delight with which those who used the first microscopes peeped into the new and unexplored world which lay before them; and as what is seen through this instrument depends quite as much on the training of the eye at the upper end as on what is placed beneath it, it is not surprising that some remarkable discoveries were announced.

Father Athanasius Kircher, in his treatise on the Pest, published in 1659, says, that with his new "Smicroscope" could be seen the extremely minute worms which cause the pest, and the writers in the next century made some similar announcements, but the theory was not fully formulated until after the cholera epidemics of 1832 and 1848, when it was urged by Dr. Cowdell

* A Saturday afternoon lecture delivered at the National Museum, Washington, D. C., Feb. 17, 1883, by John S. Billings, Surgeon U.S. Army. Reprinted from *The Sanitary Engineer*.

that this disease was due to a minute fungus which inhabits the rice plant in India. Dr. Mitchell, of Philadelphia, taught in 1844-46 that malarious and epidemic fevers were due to minute fungi, and his essay is even to-day highly suggestive and interesting. The demonstration by Pasteur that various forms of fermentation and putrefaction of organic matter are due to vegetable organisms first put the matter on a scientific basis, and within the last ten years the germ theory of disease has found many advocates.

To understand the present prevailing views it is necessary that we should know the meaning of certain terms much used in discussions on this subject, and often used in a very confused way, since the words bacteria, germs, microzymes, etc., are not only used by different authors, but by the same author at different times, in different senses. In the first place we want some word to designate the great variety of particles which we find throughout all air and water under ordinary circumstances, and which are almost invariably present in decomposing organic matter—minute bodies, most of which are perceptible only with the best microscopes, and which present the most characteristic phenomena of life. These we will call microdemes, or little living things, and under this term are included the microphytes, or little vegetable organisms, the microzoa or minute animals, the microzymes or little ferments, the microbes or microbia of Pasteur, meaning literally, little lives, the bacteria, etc. Mingled with these microdemes there are usually other minute particles which are not living, and which may be either organic or inorganic. It is often extremely difficult, and sometimes impossible, to distinguish these from the microdemes, but usually the latter may be known by the uniform size and minuteness of the granules, their independent motion, and by signs of growth and reproductive division as shown by their being found in pairs or chains. The minutest spherical forms of these microdemes are called micrococcus or little grains, and when these are joined to form a chain they are called streptococcus or arthroccus. The short cylinders or rods are called bacteria, a term which is often improperly used to include the whole class. The microphytes, properly so called, are classed between the algæ and the fungi, forming what Professor De Bary calls the Schizomycetes and Naegeli the "Spaltpilze."

At present it is not believed that these microdemes are ever spontaneously generated, or arise from any source other than living organisms. There is no proof that the microphytes which cause the various forms of fermentation, or putrefaction, develop into the higher forms of fungi, such as the common moulds; but this is not yet a settled question, and some careful observers believe that at all events certain common moulds may act as ferments. Since decomposing organic matters vary greatly in composition, and give very different products, while the microdemes which they contain also vary slightly in size and mode of grouping, it is a question whether the different results depend on a difference in the microdemes or a difference in the matter on which they are nourished.

The prevailing opinion at present is that there are many kinds of microphytes, each having special powers, and that each can only propagate its own kind within a certain limited time. But it also seems possible, that by changing the food of these organisms, and varying the temperature, the process of evolution and natural selection to fit them to their new surroundings goes on very rapidly, and that the result is the production of what might be called new species having very different habits and powers. But we must remember that all microdemes are not minute fungi, nor are they all germs. Using the words germ and organism in the ordinary sense, the germ theory is that certain diseases are due to the presence, and propagation in the system, of minute organisms which have no part or share in its normal economy. The word germ, however, is applied not only to independent organisms which originate outside the body, but also to living particles of protoplasm or cells forming, or what have formed, a part of the body itself, which are not microphytes, and can hardly be called independent organisms.

Let us now briefly consider some of the diseases produced by organisms foreign to the normal or healthy body. When these organisms are comparatively large and well known, the diseases which they produce are called parasitic. Of those which are thus produced by fungi, the best known are certain skin diseases, such as some varieties of ringworm and the so-called liver spots. One peculiar variety grows in the ear, another is sometimes found in the windpipe and lungs. These diseases are called mycoses, and are for the most part confined to the skin and mucous membranes, being those surfaces of the body which are either exposed to, or in free communication with the air. In other words, they are superficial affections, and the fungi do not appear to enter the blood, or to be generally distributed throughout the body. Even in that curious disease called mycetoma, or the fungus foot of India, where the comparatively large threads of a fungus pentetrate the foot and ramify throughout its tissues, finally destroying them even to the bones, the disease is entirely local, being confined to the affected foot; and it appears to be necessary that there should be some wound or injury of the skin to permit the parasite to gain an entrance into the interior.

One of the most important of the diseases due to fungi of the nature of the common mould is one which has for some time been known in cattle but was first observed in man about four years ago, the so-called actinomycosis. It occurs locally in the form of a tumour near the lower jaw, and also in a general or internal form, in which last case it is always fatal, The fungus seems to gain admission to the tissues usually through carious teeth, and gives rise to tumours and abscesses containing small yellow bodies, which are bundles of the threads of the fungus. Let us contrast with this a disease due to the presence of minute vegetable organisms in the blood, such as splenic fever, in which the fact that these organisms were the cause of the disease was first clearly made out. Splenic fever, also known as anthrax, contagious carbuncle, the black quarter, the Siberian plague, and malignant pustule, affects sheep, cows, and horses, and also man. In the blood of animals suffering from this affection, there are found large numbers of short, straight, motionless rods or bacteria, about as long as the diameter of a blood corpuscle. These were discovered over twenty years ago, and it was known that blood containing them transmitted the disease with great certainty, provided it was fresh. These rods, however, did not explain many of the peculiarities of splenic fever, the cause of which sometimes seems to adhere very tenaciously to certain limited localities, as, for instance, to a stable, or to one small field, where it would reappear after intervals of several years. It was found that the rods rapidly lost their vitality, and that the contagious properties of the blood containing them soon disappeared; and from this it was evident that if the contagion or cause of the disease depended on the bacteria these must exist in some other form which was more permanent. Time passed on, and a German botanist, Professor Cohn, discovered that many of the bacteria have a stage of development in which they extend into long, slender rods, or threads, which he called bacilli, and that at regular intervals in these threads there developed extremely minute, highly refractive, spherical bodies, which were finally set free by the dissolution of the threads, and to which he gave the name of spores. Upon these characters he defined a genus of plants, which he called *Bacillus*, and in view of the shape of the little rods in splenic fever blood, he ventured to predict that these would be found, under some circumstances, then unknown, to develop into bacilli and produce spores, which spores would prove to be far more permanent in their vital properties than the bacteria. This prediction was verified by a series of careful culture experiments carried out by Professor Koch. It was found that the little rods, when placed in various animal fluids suited to give them nutriment, and kept at a temperature near that of the human body, began to lengthen in a few hours, and very soon grew into slender threads, which were from twenty to a hundred times the length of the original rods. In a few hours more, minute dots began to appear in these threads and went on to form spores, which being set free, sank to the bottom of the vessel. Now these spores are found to retain their life very persistently in spite of all manner of ill-treatment. They may be wetted and dried, buried in earth for an indefinite period, but even after many years, when they are placed in contact with a proper nutritive fluid and at the right temperature, they will germinate and elongate into rods precisely like the originals from whence they sprung, and after repeated cultures in this way, the results will still produce splenic fever, when inoculated in animals, so long as and no longer than they will produce fresh rods and spores in culture fluids. Baron Seebach, of Saxony, had suffered great losses from the repeated occurrence of splenic fever on his estate, and finally began to suspect that the disease was propagated from the graves of dead animals. He observed one day that the clover was growing with great luxuriance over a place in the corner of his fields where a sheep dying of the disease had been buried two years before. A few days later he noticed that some one had stolen the clover which grew at that corner, and the next day a woman, one of his tenants, came to him with great lamentation to tell him that her goat had just died and her cow was very ill. It was found that both the animals were affected with splenic fever, and the woman confessed that they had been fed with the stolen clover. In 1865 Baron Seebach was minister to Paris, and he then drew up a memorandum giving his views, which memorandum was placed by the French minister of agriculture in the hands of M. Pasteur. He reported, after investigation, that if the carcass of an animal dying of anthrax be allowed to decompose at once with free access of air and moisture, its virulence is soon destroyed. The ordinary bacteria of putrefaction take possession and do their work, which in this case is a highly beneficent one and gives us a hint of how one species of micro-organisms may be used to drive out, destroy, or counteract the effects of others.

But if the carcass be so buried that but a limited supply of air comes to it, as in damp clay soil, the *Bacillus anthracis* goes on to form its spores, and there the locality becomes a dangerous one. These spores, buried for years, may be brought to the surface by earth worms, and thence find access through food or water to other animals.

Pasteur proved to the satisfaction of a commission appointed by the Academy of Medicine of Paris, that the germs of this bacillus were present in earth over the grave of an infected animal buried twelve years before, and also in the casts deposited by earth worms in similar localities.

Closely analogous to anthrax is the disease of hogs, known as the hog plague, which is also due to a bacillus which can be cultivated outside the living animal. The *Bacillus anthracis* is to all appearance identical with a very common bacillus, the *Bacillus subtilis*, which is found in all infusions of dried grass or hay, the only apparent difference being that the bacteroid form of *Bacillus anthracis* is motionless while that of *Bacillus subtilis* is very active. This *Bacillus subtilis* is, so far as known, a perfectly harmless form, but a possible connection between the two forms was at once suspected, and after many experiments Dr. Buchner has announced that he can, by varying the methods of culture, transform the one into the other with great certainty. After carrying on the culture of the *Bacillus anthracis* with free access of air for several hundred generations he found that it would no longer produce anthrax when inoculated, that it began to grow on the surface of the fluid, which is a characteristic of the hay bacillus, and finally that it would grow in an acid hay infusion which at the beginning of the cultures was fatal to it, in short, that it had become *Bacillus subtilis*. The reverse process was more difficult; but by limiting the supply of air and gradually substituting animal for vegetable culture fluids he finally produced malignant anthrax germs from common sweet hay. His reported results are not yet accepted as conclusive, however, and further and more careful experiments are needed to settle this question.

There occurs among fowls a disease which is commonly known as chicken cholera, not because its phenomena resemble those of cholera in man, but because it once prevailed in France at the same time as Asiatic cholera. The blood of fowls thus affected contains a microphyte which will grow and multiply in great abundance in chicken broth kept at a proper temperature. If a needle be dipped in broth containing this germ, and then dipped in other broth which has been sterilized by boiling, this last broth soon becomes turbid, and in a few days is swarming with the organisms. This process may be repeated a hundred times and a drop of the hundredth culture will produce the disease if inoculated as surely as would one from the first, nor will the disease thus produced be any the less virulent or fatal.

But if, instead of making these successive inoculations while the fluids are still turbid, and the microphyte is flourishing, we wait from one to six months, the malignancy of the microphyte becomes greatly diminished, and when inoculated upon an animal it no longer produces fatal results, and its effects seem at first to be confined to the production of some trifling local irritation. The virus has been, as Pasteur phrases it, attenuated. "The extraordinary and very important fact, if it is a fact, discovered by Pasteur, is that this tamed and attenuated microphyte does, nevertheless, produce a change in the whole system of the living animal, which is no longer susceptible to injection by subsequent exposure to the influence of the unattenuated germs." In other words, this attenuated virus acts as a sort of vaccine against the more malignant forms.

Having discovered this, Pasteur next tried to attenuate the virus of splenic fever in like manner, but at first was not successful because the bacillus when cultivated would form spores, and the virulence of these spores did not diminish. At last he found that by keeping his culture broth at a comparatively high temperature, about 100° F., spores did not form, the attenuation could be obtained, and that this attenuated virus could be used as a vaccine against splenic fever. This sort of vaccination is now undergoing a very extensive test in Europe—a large number of cattle in France, Germany and Hungary having been inoculated for this purpose.

What may be the real value of this protective inoculation is as yet uncertain; in part, because sufficient time has not yet elapsed to enable us to say whether the protection is permanent, in part, because this attenuated virus may reassume its virulent properties if cultivated in young pigs—and very possibly under other circumstances.

(*To be continued.*)

OILY SUBSTANCES IN RICE.

According to G. Campari ('Annals of the Milan Society of Applied Chemistry'), oily substances are contained in large quantities in the embryo of the rice, which he finds to be composed of 95·54 per cent. of fatty acids, and 4·46 per cent. of glycerine. Treatment with bisulphide of carbon produces a yellow wax-like substance which readily saponifies with bases, melts at 32° C., becoming quite solid at 28° C., with a specific gravity of 0·93005. It is completely soluble in ether, chloroform, and benzine; its composition appears to be C 79·2, H 10·9, O 9·9 per cent. The fatty acids melt at 36° C., emit a perceptible pear-like odour, and yield, when saponified and heated with magnesium acetate, a body which melts at 62° C., and exhibits the composition of palmitic acid $C_{16}H_{32}O_2$.

The Pharmaceutical Journal.

SATURDAY, JULY 14, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PROPOSED PHARMACEUTICAL LEGISLATION IN FRANCE.

We mentioned recently that the Commission entrusted with the consideration of two *projets de loi* dealing with the regulation of the practice of pharmacy in France that have been introduced into the Legislative Assembly had completed its report. Now that this report has been published *in extenso*, it proves to be a most exhaustive review of the whole subject and includes a number of propositions as the basis of a Bill which shall take the place of the two remitted to the Commission. The elaborate *résumé* of the inconveniences and defects of the "loi du 21 germinal an XI.," and of the many abortive attempts to amend it, with which the report opens, although full of interest, can only be mentioned here, since it will be difficult to condense within moderate bounds the many points discussed in the report which have at present a wider interest.

The first question presented for the decision of the Commission was, whether in future the practice of pharmacy in France should be controlled at all by regulations; whether, in fact, in future the diploma of a pharmacien should be simply a stamp of the State, sought for by men of science, but conferring no privilege, or whether its obtainment should continue to be required from all who wished to engage in the supply of pharmaceutical products by retail for use in medicine. It is not surprising to learn that absolute liberty had its partisans in a republican commission, and that some of the members thought both pharmaciens and the public should be free to buy or sell medicines as they please, and to attach any or no importance to diplomas as an evidence of qualification. But the majority was doubtful as to the attainment of this ideal at one bound, and looked upon abstract principles as being at present not necessarily favourable to successful legislation. The present law, however, under which it is illegal for a grocer to sell a small quantity of lime flowers, was felt to be too restrictive, and as a compromise it was agreed to recommend that there should be inserted in the Codex a list of substances used in medicine, but recognized as not being dangerous, which might be sold by any person. If this were done, the alleged necessity for the class of herbalists would cease and their certificates need no longer be issued. But with the exception of the supply of such articles, it was decided to recommend that no person should be allowed to carry on the business of a pharmacien in France, either in the supply of medicine for human beings or for veterinary purposes, without being provided with a diploma obtained in France or in a French colony and being subject to certain regulations.

Having decided that the practice of pharmacy ought to be restricted and regulated, the Commission had next to consider as to the nature of the regulations it should recommend. The first agreed to was that veterinary pharmacy should be subject to the same restrictions as the dealing in medicines intended for human beings, on the ground that otherwise the law would be liable to evasion by means of misrepresentation as to the object for which medicines were supplied. Next it was decided to recommend the cessation of the issue of diplomas of the second class, which authorize the holders to practise pharmacy only in the departments in which they are granted, it being considered illogical that a person should be held qualified to practise in one district and not in another. The third question discussed, and the decision upon it, are worthy the attention of the few persons who have objected to the introduction into the English Bill of a clause providing that branch pharmacies shall be conducted only by qualified managers. The question was whether one and the same pharmacist should own several pharmacies, and whether he ought to reside habitually in the place where his pharmacy is situated. No serious discussion, we are told, arose on this point. It was assumed, as a matter of course, that the responsibility falling on the pharmacist and the watchful superintendence he is required to exercise are alike opposed to the same person keeping open more than one pharmacy, and for the same reason it was held that he should ordinarily reside in the locality where that pharmacy is situated. A decided opinion is expressed in this part of the report that the greater the liberty of action accorded to the pharmacist, the more necessary it becomes to take every precaution that his responsibility shall be effective. It was further decided that the name of the actual proprietor of a pharmacy ought to appear on the front of the establishment and on the labels; and that where it is desired to retain the use of a familiar name, the name of the actual proprietor should be placed underneath. Another point discussed resembled one that frequently exercises pharmacists in this country, namely, whether a medical man should be allowed to practise pharmacy even if he possess a pharmacien's diploma, or to translate it into the conditions which obtain in Great Britain, whether a medical man who is a licentiate of the Society of Apothecaries should be at liberty to keep an open shop for the supply of medicines. At present this practice is allowed in France, but the Commission considered the custom to be liable to abuse and to involve the medical profession in discredit and therefore recommends it should be prohibited. It is, however, proposed in cases of urgency and when there is not an open pharmacy within six kilometres (rather more than three and a half miles) to allow a medical man or a veterinarian to supply medicine, but not to allow him to keep an open shop for the purpose. The Commission proposes also to prohibit persons not possessing a diploma from carrying on business with the aid of a qualified manager, but it would allow an association of pharmaciens, all of whom possessed diplomas, to employ a qualified manager to carry on business on their behalf, provided that the manager is also one of the proprietors. With respect to public companies it is recommended that these shall be allowed to carry on the business of a pharmacy only when the manager of the pharmacy also occupies the post of acting manager of the company. Hospitals and religious and secular communities would be allowed to have a pharmacy in connection with their operations, but only on condition that it be managed by a qualified pharmacien and that medicinal substances be not sold to persons outside the particular association. This would appear, however, to be sufficiently wide to include co-operative associations. It is also recommended that after the death of a pharmacien, his widow or heirs be allowed to keep the pharmacy open for a period not exceeding one year from the date of his death, provided that it is carried on under the management of a pharmacien, or of a pupil who is approved by the school of the district in which the pharmacy is situated.

Another class of subjects was approached in the raising of the questions, whether the supply by retail of pharmaceutical substances should henceforth be unrestricted, under the guarantee of a diploma; whether the supply of secret remedies should be published; and what should be understood by the term "secret remedies." Under the present French law, construed strictly, it is illegal for pharmaciens to supply by retail any medicinal preparations or compounded drugs whatever, except upon the prescription of a qualified medical man. But such illegalities are, nevertheless, continually practised, and it was felt unanimously by the Commission that the stringency of the law needed relaxation, the doubt being as to what extent. The opinion predominant from the first was that the pharmacien should be at liberty to sell any medicinal substance, whether poisonous or not, upon the express demand of the buyer, supplemented in the case of a poison by his signature. It was argued that since the passing of the existing law the pharmaceutical body has become more enlightened, whilst the mass of the people has become better informed; and that a pharmacien, knowing thoroughly the properties of the articles in which he deals, and remaining responsible for accidents arising through his negligence, would always be very circumspect in his transactions. Under existing restrictions a person wishing to try a remedy upon himself, which he had successfully used in another country, could not legally be supplied with it except upon the authority of a medical man, which he might not be able to obtain. The objection was raised that such freedom would promote irregular practice, and this led to the definition that if, after the removal of restriction, a pharmacien served a customer who asked definitely for twenty drops of Sydenham's laudanum, there would be no offence committed; but if, on the contrary, the customer described his case and asked for an opinion, and the pharmacien recommended him to take syrup of sarsaparilla, or any other medicine however simple, that would be an irregular transaction, which would render him liable to a penalty under the law relating to the practice of medicine. For these and other reasons the Commission had decided to recommend the granting of absolute liberty of sale under the guarantee of a diploma, but upon the intervention of the Minister of Commerce an exception was made in respect to the sale of poisons. As to secret remedies, under the present law the sale of these is prohibited, and the law courts have decided that the designation covers any medicine that is not either included in the Codex, authorized by the Government after a favourable report from the Academy of Medicine, or made up on the order of a medical man. It is evident that such a prohibition reaches a large number of specialties of known composition, and the Commission considered that it must operate as a bar to pharmaceutical progress. But it is worthy of note that the main idea of the reporter as to pharmaceutical progress is apparently the supersession of preparations made in the pharmacy by ready made goods produced on a manufacturing scale, and he mentions, with evident meaning, that already specialties are exported from France to the value of thirty or forty millions of francs annually. The Commission recommends that such preparations, when they do not contain the excepted poisons or preparations of them, shall be allowed to be prepared and sold by pharmaciens with no other restriction than that the labels shall bear the names and doses of the active ingredients, the Codex name being used when an official drug is present. On the other hand, it is considered that all "secret" preparations of undisclosed composition should be rigorously interdicted.

One other subject must be referred to briefly before closing this rather lengthy summary. The report provides for the publication of a Codex, written in Latin and in French, which it is recommended should be drawn up by a committee consisting of an equal number of professors of medical faculties, professors of superior schools of pharmacy and pharmaciens holding a pharmacy, with the addition of two veterinarians.

In the course of a statement made in the House of Commons on Monday evening with respect to public business the Prime Minister stated that the Medical Acts Amendment Bill would be proceeded with and it being one that had met with general acceptance he hoped it would become law this session. According to the *Standard*, however, the prospects of the Bill passing this session are very doubtful. The Scotch members are said to have by no means withdrawn their opposition to the clauses fixing the representation of the Universities and of the medical bodies, and it is understood that the Government is not prepared to make the desired concessions. The second reading was set down for Thursday, but at the time of going to press had not yet been reached.

* * *

At a recent extraordinary meeting of the College of Physicians a communication from the Pharmacopœia Committee of the General Medical Council was considered, and a Committee, consisting of Drs. Munk, Garrod, Ringer, Brunton, Baxter and Thudichum, was appointed to consider and report what alterations, additions or omissions, if any, it is desirable should be made in the proposed new edition of the British Pharmacopœia.

A return recently presented to the Academy of Medicine by the French Minister of Public Works is quoted by the *Lancet*, from which it appears that there are no less than 1027 mineral springs in France at the present time, of which 357 are "alkaline," 318 "sulphurous," 215 "saline," and 136 "ferruginous." In the case of 641, the temperature exceeds 59° C., and these are classed as "thermal springs," the others being called "cold springs." Of these 94 are situated in the department of the Puy-de-Dôme, 77 in the Ardèche, 76 in the Vosges, 69 in the Ariège and the same number in the Pyrénées Orientales and 64 in the Hautes Pyrénées. The department in which the largest number of persons took the waters last year was the Puy-de-Dôme. The total outflow of all the mineral springs in France is estimated at 10,334 gallons per minute.

* * *

In 1881, with an estimated population in England and Wales of 12,676,276 males and 13,379,130 females, or rather over 700,000 more women than men, there were registered 253,605 deaths of males to 238,330 of females, or an excess of 15,725 deaths of the least numerous sex. Put into another form, the male death-rate in 1881 was 20 per 1000 and the female death-rate only 17·8 per 1000, the relative proportions of the deaths being 1124 males to 1000 females. Even this shows some improvement in favour of the "stronger" sex, the average relative proportions of the deaths during the previous decennium having been 1134 males to 1000 females.

* * *

A correspondent of the *British Medical Journal* reports a case in which a woman, aged 31, recently took probably at least 7½ grains of tartar emetic and possibly double that quantity, mixed with treacle, instead of cream of tartar. The powder was taken from a previously unopened packet that was purchased about two years ago in Barbadoes, and still bore a "cream of tartar" label. The woman eventually recovered, but had the "remedy" been administered to the child for whom it was originally intended the final result would probably have been a different one.

* * *

In the island of Ceylon, at the instance of the Planters' Association, the Government has decided to allow prescriptions in cases of urgency to be made up at the dispensaries connected with the Medical Aid Ordnance, on the payment of a fee to cover the cost. The conditions are that the prescriptions shall be written in English (except the names of drugs), without symbols or abbreviations; that no medicine shall be ordered which is not in the British Pharmacopœia; that the prescriptions shall bear on the back a certificate that the medicine is required in a case of urgency; and that the medicines be paid for at once.

According to Mr. Consul Jordan the betel-nut forms a very large item of export from the Chinese island of Hainan. The two districts of the island most noted for their betel-nut groves are Ai-chou and Ling-shui, the fruit from the latter of which is considered the best. The trees are planted some 15 feet apart, and bear fruit from the age of ten to ninety years. Their most prolific period is between their fifteenth and thirtieth year, when one tree will produce seven hundred or eight hundred nuts, valued at about forty cents. Large herds of cattle are allowed to roam at will through the plantations, and their manure serves to fertilize the soil from which the trees derive their sustenance. The groves are said to be the seat of pestilential malaria, especially at the season when the trees are in flower. In preparation for the market the nut is made to assume a variety of forms to suit the fastidious tastes of the Chinese consumers, which are different in almost every province.

* * *

A new "glass," produced by fusing pure acid phosphate of lime, is reported to present several advantages as compared with ordinary glass in chemical manipulations. According to M. Sidot, the inventor, it can be made into retorts, flasks and tubing, resembling those made from ordinary glass in appearance, but which are not attacked by hydrochloric acid or even by hydrofluoric acid.

* * *

According to a writer in the *Pharmaceutische Centralhalle* a good method for making labels adhere to zinc or iron, is to carefully roughen the surface of the metal with sandpaper, then to coat it with a solution of an alkaline silicate, and lastly apply the label. It is important that the silicate solution should be painted on the roughened metal and not on the label.

* * *

It may be of interest to some readers who have experienced loss consequent upon the deterioration of indiarubber through exposure, to learn that some experiments made by Professor McLeod seem to show that caoutchouc undergoes alteration under the combined influence of light and oxygen, but that neither alone produces any effect.

The meeting of the American Pharmaceutical Association at Washington is to be held in the Smithsonian Institution, the use of a lecture room in the new museum building having been granted for the purpose by the Directory, together with ample space for an exhibition.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, July 4, in the College of Physicians, Dublin, at three o'clock.

The President, Professor Tichborne, in the chair.

The other members of the Council present were:—Messrs. Allen, Brunker, Dr. Collins, Messrs. Draper, Grindley, Hayes, Minchin, Dr. Montgomery, Sir George Owens, Messrs. Simpson and Wells.

The minutes of the last meeting having been read and confirmed,

Mr. Fennell, the Registrar, read a letter from Dr. Kaye, Q.C., Clerk to the Privy Council, enclosing a copy of a petition which had been sent to the Lord Lieutenant and Privy Council, praying for a revision of certain regulations which had been made by the Council under the Pharmacy Act (Ireland), 1875. The petitioners set forth that that Act recognized the then existing chemists and druggists as competent to carry on the business of chemists and druggists for the sale of poisons, and authorized the Council of the Pharmaceutical Society of Ireland to hold examinations for the licence of succeeding chemists and druggists; but that they had declined to do so, preserving that business for the members of the pharmaceutical body. That course, it was alleged, was an inconvenience to the public. The chemists and druggists had a body of capable assistants and apprentices who had reasonable hope of becoming in time masters of their own business, and many of them of becoming pharmacists, and in the practice of their own business they had been performing all the duties which belonged to the pharmacist, the compounding of prescriptions alone excepted. The Pharmacy Act had appointed one test of qualification only for future chemists, druggists, or pharmacists, namely, an "examination" which the Council of the Pharmaceutical Society should "cause to be held at such times and in such manner as might be prescribed by regulations made in pursuance of that Act." The regulations adopted by the Council of the Society and approved of by the Privy Council superimposed a Preliminary examination and apprenticeship, or its equivalent, neither of which was required by the Act. The effect of this was to deprive those at present trading as chemists and druggists of their right to present themselves at the appointed examination for licence. Further, the object of the apprenticeship appeared to be the gaining of experience in the compounding of prescriptions, thereby removing the safeguard the public were supposed to have under the Act, and exposing them to the dangers which must arise from allowing unregistered and legally unqualified persons to compound, more particularly youths who were only learning the business. There was nothing in the Act disqualifying a registered pharmaceutical chemist from keeping open shop *for* or *in partnership with* an unqualified person; nor would his doing so be a disadvantage to the public who would have the benefit of his ascertained skill and the capital of his principal, while in the event of accident there would be the civil and criminal responsibility of each respectively. It was, therefore, prayed that the existing regulations might be amended:—1st. By having the present dealers in poisons and drugs registered under a new Act; 2nd. By providing a test examination for the continuance of their business as such under the title of chemists and druggists; 3rd. By abolishing the Preliminary examination and apprenticeship. 4th. By recognizing the right of the registered pharmacist to keep open shop for or in partnership with an unqualified person.

Mr. Fennell read a letter addressed to the Lord Lieutenant by Mr. Robert James Downes, L.P.S.I., who had been entrusted with the presentation. A copy of this letter had also been enclosed to the Council by Dr. Kaye. The writer said the recent action of the Council in ignoring certain just claims, and then seeking to increase the impediments in the way of aspirants for their licence, had stimulated the petitioners to action in this matter. They requested His Excellency not to sanction any new encroachments, and also to withdraw the sanction already given to regulations framed for the purpose of promoting and conserving a monopoly. They maintained that the Act gave no power to impose apprenticeship or curriculum. The principle contended for in the fourth request had been admitted and acted on by the first members of the Council, and it was only of late that that body had been putting a contrary interpretation on the Act. Amongst the hardships which it entailed were, that while the 32nd section provided for the carrying on of the business of a deceased pharmacist, the widow or minors of the deceased chemist and druggist could only sell their interest, which was *nil*, to a pharmaceutical chemist, or close their business. A case had arisen where the senior partner, having been forty years in the business, put forward the son who had obtained the licence of the Pharmaceutical Society, but they could not trade as pharmacists unless the senior withdrew both himself and his capital from the business. A young pharmacist might desire to obtain or open a business, and a friend might be willing to help him, but he could not do so as a partner, though he might by a bill of sale or mortgage upon the business. It was more than doubtful that the Council of the Society had the approval of the body of their licentiates, who on January 1, 1883, numbered 219, of whom only 100 were keeping open shops on their own account, the remainder being variously employed, while 61 only were subscribing members; and last year they had only 12 candidates for the licence. Of the 21 members of the Council, 8, the writer added, were original members, one was a registered apothecary, and the remaining 12 were all admitted by examination only, without apprenticeship.

The President said that as regarded the first of the four amendments which were requested, the Council had been for the last two years petitioning to get power to register the gentlemen to whom it related. As regarded the other amendments which were sought, some of them were very peculiar and others important, and he was inclined to recommend that the petition and letter be referred to a committee, who should be requested to draw up a reply to them.

Sir George Owens said it would be a very dangerous thing to make it possible for a monster house with six partners to carry on pharmaceutical business with the aid of one pharmaceutical chemist.

The President: As regards the objections to our bye-laws bearing on the examinations, we have full power to alter the regulations from time to time; but still there are points in the letter worthy of consideration.

Sir George Owens said he did not want to dictate to whatever committee the documents should be referred to, but he hoped they would not throw overboard the practice of apprenticeship. The amount of ignorance of necessary manipulations that was displayed by physicians, surgeons, and other men having university degrees, was surprising.

Mr. Simpson: The apprenticeship is a thing that we should stick to through thick and thin.

Mr. Hayes: The root of the complaint is that the chemists and druggists cannot take apprentices who want to go on to the higher grades of pharmaceutical chemists, and that that throws the necessary apprenticeships into the hands of the pharmaceutical chemists.

On the motion of the President, seconded by Mr. Allen, the petition and letter were referred to the Law Committee.

The Registrar read a letter from Mr. James N. Hardy, L.P.S.I., of the City of Dublin Drug Hall and Plate and Sheet Glass Warehouse, No. 17, Lower Sackville Street. The writer stated that he had found by the report of the last meeting of the Council that they had declined for the present to give a definite answer to a question put by Mr. Curham as to whether they would accept from him (Mr. Hardy) a certificate of practical pharmacy for Mr. Curham's son. Clause 2 of the syllabus for the final pharmaceutical examination declared that candidates must produce a certificate of having been engaged in compounding and dispensing in the establishment of a pharmaceutical chemist "keeping open shop;" and he (Mr. Hardy) maintained that he did that strictly in accordance with the Act, which evidently meant a shop to which the public could have access, and where an apprentice or assistant would obtain the experience of an ordinary pharmacy. As he understood, the difficulty was occasioned by his being in partnership with Mr. Beater in the general family drug business. But certificates from the qualified members of the firms of Messrs. Boileau and Boyd, Boyd and Goodwin, W. Hayes and Co. (from 1875 to 1878), and, he doubted not, others who had non-qualified men for their partners, had not been refused by the Society; and the Act of 1875 actually named four gentlemen, Messrs. Goulding, Goodwin, Hayes and Hodgson, who were thus circumstanced, and bestowed upon them all the privileges of pharmaceutical chemists. Again, when the Council recently called on two houses to cease compounding, the reason alleged was that the qualified member had in one case died, and in the other withdrawn. His (Mr. Hardy's) case, however, was different from that of a "composite firm," for by an agreement of April 17, 1883, he rented from his firm a portion of the premises where their general business was carried on, to be used by him as a compounding department. He was the sole legal proprietor of that compounding business; all dispensing was done in his name; and apprentices would be engaged to himself personally. He therefore submitted that the fact of his having a partner not a pharmaceutical chemist in another business did not disqualify him from giving such a certificate as the Society could accept; and he thought that on further consideration the Council would see that his case was wholly different from that of Mr. Grindley.

Mr. Brunker said Mr. Hardy appeared to have made very elaborate preparations to evade the law, and the only question was whether he was evading it successfully or not. A somewhat analogous case was mentioned in the *Pharmaceutical Journal* of last week. An analytical chemist was prosecuted by the Pharmaceutical Society of Great Britain for selling poisons. His defence was that he had a qualified assistant whom he allowed to sell the poisons in his shop. It did not appear that he had a separate counter for the purpose, but the qualified assistant was in the habit of selling the poisons on his own account. The employer, however, was fined, as he was the person supposed by law to be "keeping the open shop." Now, in the case of Messrs. Beater and Hardy, if there was but the one entrance to the shop, but a portion of it inside was set apart for Mr. Hardy, an acute lawyer might raise a question as to who it was that kept the "open shop;" but he (Mr. Brunker) maintained that it was the firm of Beater and Hardy, and not Mr. Hardy.

Mr. Grindley: It is not the business of the Council to settle a question of that kind.

Mr. Simpson: According to Mr. Hardy's argument he would be entitled to issue certificates from a compounding department in the establishment of Messrs. Arnott and Co.

Mr. Wells said he had seen an account of another case in England, in which a man who sold poisons in a part of his shop was convicted, and had to pay the full penalty.

Dr. Montgomery said this was a very complicated question, and they should leave Mr. Hardy to get a legal opinion for his own guidance.

The President remarked that Mr. Hardy represented himself to be the sole proprietor of the department. That made his case somewhat different from the others.

Mr. Simpson: He rents a counter in the shop, but his name is not outside the door anywhere.

The President: But his name is on the labels, "J. Hardy, Pharmaceutical Chemist."

Mr. Brunker moved the following resolution:—

"That in reply to Mr. Hardy's letter of the 22nd ult., he be informed that the query addressed by him to the Council is a purely legal one, to which they are not in a position to give any other answer than that addressed to Mr. Curham."

Mr. Hayes seconded the motion.

Mr. Simpson moved by way of amendment—

"That the letter of Mr. Hardy be referred to counsel for an opinion and advice."

Mr. Draper seconded the amendment.

The amendment was negatived by six votes to four and the original resolution was carried.

A letter was read from Mr. John I. Pierce, of Trim, stating that he had served four years with Mr. H. Byrne, chemist and druggist, of Marylebone, London, and that he had been assistant to a pharmaceutical chemist for twelve months; and he desired to know would a certificate from the first-named gentleman admit him to the Society's examination qualifying for a pharmaceutical chemist.

The President remarked that the regulation restricting the persons with whom the two years' compounding and dispensing should be spent to pharmaceutical chemists and apothecaries should not be on their books at all. It was said through the city that their object was to prevent men from coming up for the examination; that the student in England got as much experience in compounding with the chemist and druggist as with the pharmaceutical chemist.

Dr. Montgomery: But we should keep up the *prestige* of the Society. I would not go in for admitting chemists and druggists to complete equality.

Mr. Brunker: The bulk of the dispensing body in England are only chemists and druggists.

The Registrar was ordered to inform Mr. Pierce that the certificate he offered could not be accepted under the present bye-laws.

The result of inquiries made in the case of Mr. Hance having been reported to the Council, it was ordered that the Registrar should inform him that his certificates of practical pharmacy could not be accepted.

The President reported the result of inquiries which had been made by a Committee appointed to look out for new premises for the Society.

A resolution was passed authorizing the Committee to complete the negotiations for renting of premises in Harcourt Street.

A petition, which the President and members of a Committee had by authority of a resolution passed at the last meeting of the Council drafted and forwarded to Parliament, praying that members of the pharmaceutical bodies of the United Kingdom should be represented on the Committee for the revision of the Pharmacopœia, and also that the new Medical Bill should be amended so as to restrict general practitioners under it from compounding and dispensing medicine to any but their own patients, was submitted and approved of.

The President moved, pursuant to notice—

"That on and after October 1, 1883, the office of President of the Society shall not be held for more than three consecutive years by the same person."

Two or three other members of the Council concurred with him in thinking that the presidentship should not be permanently held by one member of the Council, but should be movable to a certain extent. When a gentleman had occupied the office for a succession of years a delicacy was felt about removing him, and that feeling was likely to increase the longer he was left in office; and on the other hand it might happen that the opinions of the President might cease to be in harmony with those of the rest of the Council on important points, and at the same time they might not like to oppose him in reference to those matters, or he them.

Mr. Simpson said he quite concurred in the observations made by the President, and had great pleasure in seconding the motion.

The resolution was unanimously passed.

Some other business having been disposed of; the Council adjourned.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

Annual Meeting.

The Second Annual Meeting of the Society of Chemical Industry was held on Wednesday morning last, in the Lecture Theatre of the Institute of Civil Engineers, Great George Street, Westminster. The chair was taken at 11 o'clock by the President of the Society, Sir Frederick Abel, C.B., F.R.S. After the minutes of the last annual meeting, held in Birmingham, had been read and confirmed, the Chairman called upon the General Secretary to read the following:—

Report of the Council.

"In the first report of the Council the number of members on the Society's Register was stated to be 297. At the last annual meeting, the President announced that there were on the list 1140 members, and at the present time there are 1390 names on the Register, 8 having been lost by resignation and 7 by death.

"The local sections of London and Liverpool have been doing active work during the past year, and in October last an addition was made to these by the establishment of a Manchester section.

"The Council has also to congratulate the members upon the amalgamation of the Newcastle Chemical Society as a section of this Society.

"The Journal has been carried on much upon the same lines as last year, but numerous additions have been made to the Publication Committee in order to ensure more complete and systematic revision of the matter contained in it. It has sometimes been difficult to keep the Journal within the limits which the income of the Society imposes on it, but the Council has arranged that individual numbers shall not be strictly limited to a particular size when matter of interest is in the hands of the editor, which it is desirable to disseminate amongst the members without delay.

"It is satisfactory to note that several of the suggestions made to Mr. Chamberlain in a letter published in the July number of the Journal last year have been adopted in the Government Patent Bill.

"The Patent Laws Committee has had several meetings and its report to the Council will be submitted to the members.

"The Council has to submit to the members the proposal that a Parliamentary Committee be appointed to watch over all legislation affecting the future welfare of chemical industry.

"Early in the year the Council appointed a Committee to revise the bye-laws. The recommendations of that Committee have been carefully considered, and the bye-laws, amended in accordance with them, are submitted to the members for their approval.

"It has been found that the present mode of electing members entails considerable delay, and steps are now recommended to remove this. Some gentlemen may have been deterred from joining by the existence of an entrance fee, which it is, therefore, proposed to abolish.

"It is proposed to abolish the offices of honorary metropolitan and northern secretaries, as the secretaries of local sections (which, with the chairmen, it is proposed to place upon the Council) perform the duties which it was thought, in the first instance, would devolve upon those officers.

"The Council has also recommended an alteration of the office of General Secretary, it being desirable that this office should be thoroughly at the disposal of the Council and of Committees, and that he should not occupy the anomalous position of servant of the Council and member of that body.

"The Treasurer's report will show that the Society is in a good and sound financial position, at the same time it is the duty of the Council to call the members' attention to the circumstance that the arrears of unpaid subscriptions are somewhat heavy. In view of this the Council has been compelled to carefully revise the rule which makes a continuance of the privileges of membership contingent upon the fulfilment of the obligations which it entails."

The report of the Treasurer (Mr. E. Rider Cook) was then read, which showed that at the end of the year 1882, the date up to which the accounts had been audited, there was a balance in favour of the Society of upwards of £600. An informal supplemental account read by the Treasurer showed that this balance had since been augmented to upwards of £900.

The Chairman then proceeded to deliver his Presidential Address. After a few preliminary words of welcome, Sir Frederick Abel congratulated the members upon the rapid development of the Society, which he attributed chiefly to two causes: the provision as to the meetings of sections or local branches, and the existence of the Journal. Last year the Chairman was able to announce that sections had been established in London and Liverpool; this year he was able to say that there was a third at Manchester, and through the amalgamation of the long-established Newcastle-on-Tyne Chemical Society, a fourth at Newcastle; whilst it was probable that there would soon be a section established in Birmingham, as well as one in Ireland. It had been thought desirable to depart from the custom of having a series of papers read at the general meetings, in order that as many communications as possible might be available for the meetings of the local sections, and it had been proposed that the annual meeting should be the occasion of the delivery of an address upon some topic of interest to the members by a person specially qualified to speak upon the subject. The proposal had commended itself to his judgment, and he had hoped himself to have inaugurated the practice by an address upon the subject of explosives, to which his attention had been principally directed. The numerous calls upon his time by official and other duties had prevented this, but he would nevertheless lay before the meeting, in an informal way, some information that might prove interesting. Sir Frederick Abel then entered upon what turned out to be a very lengthy *résumé* of the history of explosives, of which the following is only a brief outline. He commenced by remarking, that up to within the last quarter of a century very few important modifications had been introduced into the processes for making gunpowder, and even in the present day some of the old methods are followed in a few powder mills on the Continent. As a rule, however, improved methods had been adopted for granulation, charcoal burning in retorts had displaced the older process, and more attention was paid to the purification of the saltpetre. For a long time there had been little advance in blasting agents, the low-priced blasting powder holding its own, but now the miner had become critical in his choice of blasting materials. Many such compounds that had been introduced had enjoyed but a brief existence. The speaker referred in detail to some of these, pointed out the advantages presented by compressed cylindrical charges, referred to the plan of submitting the materials to a heat above the melting point of sulphur, and to attempts to substitute hydrocarbons for charcoal, and many others, the rationale of which was unfathomable by the chemist.

In the case of firearms it was necessary to use a material more under control and less uncertain in the violence of its action than was required for blasting operations, and this had proved an obstacle in the way of the utilization of gun-cotton. Various plans for overcoming this difficulty were described, and this was followed by an interesting account of recent progress in the development of the manufacture of powder, which was illustrated by specimens of pebble, prismatic, and the enormous cylindrical powder. Sir Frederick Abel admitted, however, that results nearly equal to those yielded by the best of these had been obtained by the Italians, at Spezzia, in using an irregular powder made by breaking up cakes possessing different degrees of inflammability. Nitroglycerine, dynamite, blasting gelatine and similar explosives were then passed in review, and this portion of the address concluded with a reference to Dr. Sprengel's proposal to treat hydrocarbons or their nitro-derivatives with nitric acid, and some of its possible applications. Finally, the Chairman referred to some of the topics in the report, and mentioned that the General Secretary, Mr. George Davies, having resigned, the Council had decided to engage a paid secretary, and had appointed Mr. G. C. Cresswell.

At the close of the address a vote of thanks to the President was proposed by Dr. Longstaff. The motion was seconded by Mr. John Williams, and carried unanimously.

The report of the Patent Law Committee was then read by Mr. Ludwig Mond, who stated that alterations in accordance with two out of the three recommendations contained in it had been made in the Government Patents Bill during its passage through the Grand Committee.

The adoption of the report was moved by Mr. Weldon, seconded by Dr. Longstaff, and carried unanimously.

Mr. Muspratt then moved the adoption of certain alterations in the bye-laws in the direction indicated in the report of the Council, to facilitate the election of new members more promptly, and to fix a limit with respect to the arrears of subscriptions.

The motion was seconded and carried unanimously.

Mr. Chance moved the appointment of a Parliamentary Committee, to consider and report upon any proposed legislation that might affect chemical manufactures. Mr. Chance pointed out that it would be advisable that such a Committee should be as widely representative as possible, since the interests of the members would not always be identical, as, for instance, in the case of any Bill dealing with the pollution of streams.

The motion was seconded by Mr. Mond, and carried unanimously.

Mr. Muspratt then proposed that Mr. Walter Weldon should be chosen to fill the office of President of the Society during the ensuing year, and in doing so enlarged upon the important services rendered by that gentleman in connection with applied chemistry, and especially in the alkali manufacture.

The nomination was seconded by Mr. David Howard, and carried with acclamation.

Sir Frederick Abel having vacated the chair, it was taken by Mr. Weldon, who briefly returned thanks for the honour conferred upon him.

The next business was the election of the new Council, and Scrutineers were appointed to examine the balloting papers. During their absence,

It was resolved, on the invitation of Mr. Lowthian-Bell, supported by Mr. Pattinson, jun., that the next annual meeting of the Society be held in Newcastle-on-Tyne, the exact date to be settled by the Council after consultation with the Local Section.

The Scrutineers then presented their report, and the Chairman declared that the Council for the ensuing year would be constituted as follows:—

President:—Walter Weldon, F.R.S. *Vice-Presidents*:—Sir Frederick Abel, C.B., F.R.S., I. Lowthian-Bell, F.R.S., George E. Davis, Dr. J. H. Gilbert, F.R.S., F. H. Gossage, David Howard, D. B. Hewitt, M.D., E. K. Muspratt, H. Lee Pattinson, W. H. Perkin, F.R.S., Professor H. E. Roscoe, F.R.S., Sir William Siemens, F.R.S. *Ordinary Members of Council*:—Eustace Carey, Alexander Chance, Professor Charles Graham, Peter Greiss, F.R.S., James Mactear, Rudolph Messel, John Pattison, B. S. Proctor, Dr. Angus Smith, F.R.S., John Spiller, John Williams, P. J. Worsley. *Treasurer*:—E. Rider Cook. *Foreign Secretary*:—Ludwig Mond.

This concluded the business of the meeting.

The Annual Dinner.

On Wednesday evening, a number of the members sat down to dinner together at the Freemasons' Tavern. The chair was taken by the retiring President, Sir Frederick Abel, C.B., F.R.S.

At the commencement of the after-dinner proceedings the Chairman read a telegram from Professor Roscoe, expressing his regret at not being able to be present and his wishes for a successful meeting.

After the usual loyal toasts had been duly honoured,—

Mr. Lowthian-Bell proposed the toast of the Houses of Parliament, remarking that he must advocate its acceptance upon the basis rather of the traditions as to what the Legislature had done in the past than what it was doing now. Most of those present were suffering from the evils of over-production, a condition from which the House of Commons was at present singularly free. However, as a rule, manufacturing chemists only wished to be let alone. He associated with the toast the name of Mr. Samuelson, M.P., President of the Iron and Steel Institute.

Mr. Samuelson, in acknowledging the toast, said he thought Parliament would probably leave chemists alone just as long as they left the public alone, but when they commenced to pollute the water or foul the air they must expect to be interfered with. As President of the Iron and Steel Institute he represented a body of men who were much indebted to the studies of chemists, since preliminary investigations could be carried out in the laboratory that could not be satisfactorily made with the blast furnace. So much was the iron industry dependent upon the application of chemical principles that he was of opinion that if the Society of Chemical Industry had been then in existence the Iron and Steel Institute, instead of being established as a separate society, would probably have formed one of its sections. As to the House of Commons, the present one had made considerable progress with a Bill that would give great protection to inventors and would affect many present for evil or for good; he hoped, for good. Any shortcomings of this branch of the Legislature were referable to the electors who chose it and had power to make it reflect public opinion, and he called upon the Society of Chemical Industry to make its voice heard upon subjects in which it was specially interested, just as chambers of commerce and similar bodies made their influence felt.

Dr. Perkin, President of the Chemical Society, proposed the toast of the evening, "The Society of Chemical Industry," coupling with it the name of the new President, Mr. Walter Weldon. He said the work now undertaken by the Society of Chemical Industry was formerly done to some extent by the Chemical Society. Specially trained chemists were capable of rendering great services to manufacturers, but he was of opinion that at present a sufficient provision did not exist for training in good chemical schools; what was lacking was thoroughness.

Mr. Weldon, in replying, said that considering the vastness of the scale on which chemical industries were carried on and the extent to which they contribute to the wealth of the country it was a wonder that the Society of Chemical Industry had not been established earlier than it was. A debt of gratitude was owing to Professor Roscoe for the important place given to technical chemistry in the great educational institution in Manchester with which he was connected, but a far greater one for the part he had taken in the foundation of that Society. Mr. Weldon thanked the members for the honour they had conferred upon him that day by electing him to the office of President, and expressed a hope that when the Society met next year at Newcastle-upon-Tyne it would be found that he had not been an unprofitable servant.

Professor Odling proposed the toast of "The Scientific Societies." After referring to the loss the scientific world had recently suffered in the death of Mr. Spottiswoode, he associated with the toast the name of the Treasurer of the Royal Society, Mr. Evans, who, he said, carried on a large manufacturing industry, involving chemical operations, and was himself a student in many sciences.

Mr. Evans briefly acknowledged the compliment.

The Chairman, in proposing the toast of "Our Visitors," referred to the pleasure many of the company had experienced that day in visiting the Lambeth Art Pottery, and mentioned the name of Mr. Doulton as one who had applied the highest development of the national art schools in conjunction with a chemical industry.

Mr. Doulton said that the origin of the art potteries in Lambeth might be attributed to his life-long affection for the potter's wheel, and amongst the work done by himself in his younger days on the wheel was the making of some special apparatus required by the Chairman in his earlier experiments.

The next toast was that of "The President." It was proposed by the Treasurer of the Society, Mr. Cook, who said that in his relations to the business of the Society during his year of office Sir F. Abel had shown himself to be not only a man of science but a man competent to manage affairs.

Sir F. Abel briefly replied, saying that some difficulties inseparable from the early life of such a Society had been met with and overcome, and he felt confident that the future of the Society was comparatively clear.

The last toast was "The Officers of the Society," proposed by the Chairman, who coupled with it the name of Mr. Tyrer, the indefatigable Secretary of the London Section, to whom so much of the success of the meeting was due.

This well-deserved compliment was received with acclamation, and appropriately acknowledged by Mr. Tyrer.

During the evening an admirable selection of vocal music was sung by a company of gentlemen, most of them members of the Society, which had been organized by the London Secretary.

Visits to Manufactories.

On Wednesday afternoon, a considerable number of members were, by the kind arrangement of Mr. Doulton, conducted over the Lambeth Art Pottery.

On Thursday morning a numerous company were conducted over the South Metropolitan Gas Works; after which they visited the Hammond Electric Light and Power Company's works in Bermondsey Street, where the ingenious invention of Mr. Mackie for blowing the glass capsules for incandescence lamps, the exhaustion of the capsules and other details were shown. In the afternoon a party went, at the invitation of Sir F. Abel, on a visit to Woolwich Arsenal. Other parties visited the premises of the Electrolytic Company and the Vacuum Pump and Ice Company, and the Edison Central Station.

On Friday the arrangements were to visit Messrs. Duncan and Co.'s Sugar Refinery, Messrs Ohlendorf's Guano and Chemical Works, and Messrs. John Knight and Son's Soap Works, Victoria Docks; proceeding from thence to the Lager Beer Brewery and Crystal Ice Factory at Tottenham, and returning to town in time for the Conversazione and Reception by the President of the Society of Chemical Industry, the Chemical Society, and the Institute of Chemistry, held in the Galleries of the Institute of Painters in Water Colours, and the Prince's Hall, Piccadilly.

Correspondence.

A Query requiring an Answer.

Sir,—Recently the profession has deemed itself startled by Dr. Paul's revelation that the fluid extract of cinchona is deficient in the alkaloids of the bark, but I cannot understand why it should be so.

If water alone could extract the alkaloids, why, may I ask, is it necessary to employ acids to do so? If, again, acids are indispensable for the purpose, it stands to reason that water alone cannot extract the constituents of the bark; therefore, to call the B.P. preparation Extractum Cinchonæ Liquid. is a misnomer, and for anyone to advertize a preparation containing all the alkaloids and call it "Extract. Cinchonæ Liquid." is equally so.

I can understand making a fluid extract as by the B.P. process, and adding to it definite quantities of the alkaloids of the bark and then calling it Extractum Cinchonæ Liquid., but until some better process is devised than the one in the B.P., we are really without an extract representing the constituents of this valuable agent.

50, *Elgin Crescent, W.* Percy Wells.

The New Patents Bill.

Sir,—The discussion at the Council table on the subject of the 94th section of this Bill, now before the Grand Committee of the House of Commons, is really a most important one, inasmuch as there are, I imagine, amongst printers none who do not regularly keep in stock a set of labels with the royal arms thereupon, and these are from time to time supplied to chemists throughout the world; so that whilst recognizing the right of the Legislature to put any reserve desired upon the arms of the nation, would it not be fair if representation could be made in the proper quarter drawing attention to that fact? For it is no doubt largely the pride and loyal habits of the commercial element of the English people which has induced their adoption, and any sudden law of the nature proposed would be productive of considerable loss and inconvenience to a wide section of the community (besides chemists). On the other hand, it occurs to me to ask, whether, as an alternative, there would be any objection to the use of the royal arms of Germany, Belgium, or indeed the Republics of France and America, in the event of further restriction being placed upon those of the United Kingdom of Great Britain and Ireland?

35, *Baker Street, W.* A. W. Postans.

Easton's Syrup.

Sir,—In reply to "John," in last week's Journal, I beg to state that I have been in the habit of making my Easton's syrup with the sulphate of quinine for some time now, and get a most satisfactory preparation; it is perfectly transparent and keeps well. My receipt is—

Quiniæ sulph.	96 grs.
Acid. phosph. dil.	℥iij.
Liq. strychniæ	ʒvj.
Liq. ferri phosph. (1–5)	℥ij.
Syrup. simp.	ad fl. ℥xij.

Modus operandi: rub up the quinine in a mortar with a little (℥ij.) syrup, add the acid. phosph. and liq. strych., then the liq. ferri phosph., and make up to ℥xij. with the syrup.

Scotus.

M. H. Dumes.—Such a practice would be quite optional, and we do not think it is at all usual.

J. Constable.—You appear to lose sight of the fact that the examination is not a technical one, but is intended as a test of the general education of the examinee.

Broad.—Extractum Ergotæ Liquidum, B.P.

Communications, Letters, etc., have been received from Messrs. D. Stewart, Constable, Kay Brothers, Roberts, Broad.

THE ACTION OF SOME POLYHYDRIC ALCOHOLS UPON BORAX,

INCLUDING THE CHEMISTRY OF GLYCERINUM BORACIS AND MEL BORACIS.*

BY WYNDHAM R. DUNSTAN,

Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society.

The experiments described in this paper had for their object the elucidation of the general character of the reaction between polyhydric alcohols and sodium pyroborate (borax). In the instance of one of these alcohols, namely, glycerol (glycerin), the reaction has been studied by my friends, Dr. Alfred Senier and Mr. A. J. G. Lowe, who have already published some results to which I shall subsequently allude. They have since been independently engaged in a much more detailed inquiry into this same reaction. This inquiry is still in progress, but I learn that some of the results are similar to those described in this paper. It will be convenient here to recapitulate the principal work which has been done upon this subject.

In 1877, Iles (*Chem. News*, xxxv., 204) recorded the fact that a mixture of borax with glycerin imparts a green colour to the flame, and proposed to utililize this fact as a test for borates.

In 1878, D. Klein (*Bull. Soc. Chim.*, xxix, 195) showed that when certain polyhydric alcohols are added to a solution of borax an acid reaction is the result; this was observed with glycerol (glycerin), mannitol (mannite), erythrol (erythrite), levulose, dextrose, α-galactose and β-galactose. A special study was made of the reaction in which mannitol is involved, and published in the same year (*Bull. Soc. Chim.*, xxix, 357). Klein found that when half a molecular weight of borax is dissolved in water and added to one molecular weight of mannitol, also in aqueous solution, the resulting liquid is neutral; but when the quantity of borax added was less than this quantity, the liquid is acid. From the neutral liquid a compound was obtained of one molecule of borax with one molecule of mannitol. From the acid liquid, after fractional precipitation with alcohol of different degrees of strength, a residue was obtained which was very acid, and was supposed to be a compound of mannitol with boric acid, but was not further examined. By heating together mannitol and boric acid to 150° C. for seven or eight hours, treating the resulting substance with water and barium carbonate, and subsequently purifying by precipitation with alcohol, a substance was obtained which Klein calls barium biboromannitate $\left.\begin{matrix} C_{12}H_{12}O_{10} \\ 2\,BO_3 \end{matrix}\right\} BaO$. This was decomposed by sulphuric acid, yielding a compound which crystallized into needles, but did not receive further investigation. The results of Klein's work which bears upon the present question amounted to showing that when mannitol is added to an aqueous solution of borax two compounds are formed depending upon the amount of mannitol present. If the borax be in excess, a compound of borax and mannitol, molecule for molecule, results; if the mannitol is in excess, a compound with boric acid is formed, the exact composition and properties of which were not determined, analogy leading to the supposition that it was a conjugate acid.

In the same year, Senier and Lowe (*Pharm. Journ.*, [3], viii., 819) published the results of experiments on the action of glycerol upon borax, from which it appeared that free boric acid was liberated and a more basic borate formed. Experiments made with a view of isolating the free boric acid, either directly or indirectly, gave negative results. These same observers (*Journ. Chem. Soc.*, xxxiii., 438) proposed to utilize the fact that a mixture of glycerol and borax yields a green colour to the flame as a test for glycerol, for they found that the reaction was not shared by the majority of polyhydric alcohols, erythrol and glycol alone resembling glycerol in this respect. In 1881, Donath and Mayrhofer (*Zeits. für anal. Chem.*, xx., 379) found that the acid solution resulting from the action of glycerol upon borax became alkaline when heated, and proposed this reaction as a test for glycerol. In 1882 (*Pharm. Journ.*, [3], 257), I showed the limits of this test and proposed a new method of applying it, at the same time pointing out that it could not be relied upon as a distinctive test for glycerol unless special precautions were taken to exclude other polyhydric alcohols, for I had found that the same reaction was given by mannitol, erythrol, guaiacol, pyrogallol, saligenol, dextrose, levulose, lactose and mycose, and in fact might be considered to be characteristic of all polyhydric alcohols. Since that time my work has been extended with the view of discovering the *rationale* of the general reaction.

Action of Glycerol upon Borax.—When anhydrous borax and anhydrous glycerol, the latter in excess, are heated together the mixture becomes acid and imparts a vivid green tinge to the flame. Anhydrous borax and anhydrous glycerol, the latter slightly in excess, were heated to a temperature of 120° C. As the temperature neared 100° C. water began to be abundantly given off, but it was necessary to raise the temperature to 120° C. in order to effect entire expulsion of the water. Very many experiments were made with varying quantities of the two substances to estimate the amount of water given off and so to determine the formula of the compound produced, but no reliable results were obtained, owing to the inevitable loss of glycerol at this temperature. The mass obtained in the above manner, and which gave the boron flame reaction, was reduced to powder and extracted with ether, which removed a glassy, uncrystallizable, extremely deliquescent body. It was freely soluble in alcohol and was left as a gummy film after the spontaneous evaporation of the alcohol. Upon treatment with a small quantity of water it yielded a mass of crystals which were recognized by the usual tests as boric acid. The original substance imparted a vivid green tinge to the flame, was not appreciably acid to test paper, but on moistening the paper with water became powerfully so. The acidity of the aqueous solution was not affected by ebullition. In another experiment a mixture of anhydrous borax and anhydrous glycerol was heated to 120° C., the borax being in excess; the mass upon extraction with ether yielded the body just described. It was in like manner decomposed by water, and glycerol was found in the aqueous solution by mixing with lime, drying and exhausting with ether. Absolute alcohol also extracted this substance without decomposition from the original mass, but in this case

* The part of this investigation which concerns the chemistry of Mel Boracis formed the subject of a Report upon Organic Chemistry to the School of Pharmacy Students' Association, on May 24, 1883.

it was associated with sodium borate. The residue, after extraction with ether, was found to contain a basic borate, probably sodium metaborate. The above experiments are conclusive in showing that the primary action of glycerol upon sodium pyroborate under the above conditions results in the formation of a compound which is evidently a boric ether of glycerol, that is, glycerol in which some of the hydroxyl has been displaced with the formation of water by the boric radical. This ether may be termed *glycerol borin.* It is decomposed by water, forming boric acid and regenerating glycerol; hence the acidity of aqueous mixtures of glycerol and borax. The glycerol borin produced in the manner above described agrees in its main properties with the boric ether of glycerol isolated by Schiff and Becchi (*Compt. Rend.*, lxii., 397) from the action of heat upon a mixture of glycerol and boric acid, which was represented by the formula, $C_3H_5BO_3$. Glycerol, then, acts upon sodium pyroborate, combining with half the boric anhydride which the salt contains to form glycerol borin, sodium metaborate remaining.

Action of Mannitol upon Borax.—The experiments of Klein upon this subject, which have been previously described, are open to the objection that water was employed in order to obtain the final products. My previous experiments with glycerol had shown that water annihilates the glycerol borin which results from the action of glycerol upon borax, and therefore had a similar ether been produced in the present instance it would have been *ex hypothesi* decomposed by the water employed in Klein's experiments. For this reason, my experiments in the first place were made in such a manner as to exclude the use of water. Anhydrous mannitol and anhydrous borax, the former being slightly in excess, were heated together to a temperature of 140° C. The deliquescent mass thus obtained, which gave no green flame reaction, was extracted with anhydrous ether. The ethereal solution upon spontaneous evaporation yielded a body which apparently crystallized in feathery tufts and gave an intensely green flame reaction. Absolute alcohol extracted from the original mass the same substance, together with unaltered mannitol and sodium borate. The body thus obtained was easily soluble in absolute alcohol and this solution was faintly acid in reaction. Water likewise dissolved this substance, and the aqueous solution, which was strongly acid, yielded the reactions for boric acid and also for mannitol. The residue which had been extracted with ether was found to contain sodium metaborate. An aqueous solution of borax was treated with an aqueous solution of mannitol, until strongly acid, and evaporated to dryness; then exposed for some time to a temperature a little exceeding 100° C. Ether extracted from this mass the substance above described. These experiments indicate that the action of mannitol upon borax gives rise to the formation of a boric ether in which some of the hydroxyl of the mannitol is replaced by an equivalent amount of the boric radical. This substance, which may be termed *mannitol borin*, is decomposed by water, yielding mannitol and boric acid; the acidity of aqueous mixtures of mannitol and borax is, therefore, due to this acid. There are probably many secondary reactions involved when aqueous mixtures of mannitol and borax react and some of these doubtless give rise to the formation of the bodies described by Klein. It has already been observed that a mixture of mannitol and borax, unlike a mixture of glycerol and borax, does not impart a green colour to the flame, although, as the above experiments show, a substance possessing this property, namely, mannitol borin, is present in the mixture. Klein (*Bull. Soc. Chem.*, xxix., 368) supposes that this is due to the interference of mannitol, which, acting like tartaric acid, masks the green flame reaction of boric acid when heated with it. This is a possible explanation, but the fact may also be due to dissociation, as I have shown that it is in the instance of a similar phenomenon which will be considered later on.

Action of Dextrose upon Borax.—The first experiments upon this subject were made with commercial glucose. An aqueous solution of this substance was mixed in excess with an aqueous solution of borax until the mixture was strongly acid; the solution was evaporated to dryness and the residue heated for some time at 110° C. The mass thus obtained did not give any green flame reaction and was not acid. It was extracted with absolute ether and the ethereal solution upon evaporation left a white residue which imparted a vivid green tinge to the flame. This substance was easily soluble in alcohol and this solution was only faintly acid; it also dissolved readily in water, and this solution, which was strongly acid in reaction, deposited crystals of boric acid and gave plentiful evidence of glucose with Fehling's solution. From the original mass absolute alcohol extracted the same substance in an impure condition. These experiments were now repeated with pure dextrose, the dextrose and anhydrous borax, the former slightly in excess, being heated together to about 140° C. Absolute ether extracted from this mixture a substance which behaved in precisely the same manner as that obtained from commercial glucose. The residue contained sodium metaborate.

The above experiments show that dextrose decomposes borax, forming a compound which is probably a boric ether similar in character to those ethers which have been obtained from glycerol and mannitol; sodium metaborate is at the same time produced. This ether may be termed *dextrose borin.* It also follows from the above experiments that the acidity produced when aqueous solutions of dextrose and borax are brought together is due to boric acid. A mixture of dextrose and borax resembles a mixture of mannitol and borax in giving no flame reaction for boric acid and probably for the same reason.

Action of Levulose upon Borax.—Pure levulose was prepared from invert sugar by Dubrunfaut's method. It was heated with a small quantity of anhydrous borax to a temperature of 120° C. and extracted with absolute ether. In this way a substance was obtained which behaved in the same manner as the similar body obtained by the action of dextrose upon borax. An aqueous solution of levulose was added to an aqueous solution of borax until a strongly acid reaction prevailed. The liquid was evaporated to dryness and heated to 120° C. until all the water was expelled. Ether extracted from this mixture the same compound that was obtained by heating the anhydrous substances together. Sodium metaborate was found in the residue which had been extracted by ether. Thus levulose decomposes borax, forming a compound, probably a boric ether, which is decomposed by water, yielding boric acid and regenerating levulose; it may be termed *levulose borin.* An aqueous solution of borax to which excess of levulose has been added consequently contains boric acid, but yet this solution gives no flame reaction for boric acid.

The Chemistry of Mel Boracis.—In connection with the above results it was interesting to examine the mel boracis of the British Pharmacopœia which is practically a solution of borax in honey. Mel boracis in its normal condition is acid in reaction, but gives no flame reaction for boric acid. If some of it be mixed with a small quantity of water it is found to be strongly acid, but if large excess of water be added it becomes alkaline. Some mel boracis was exposed at a temperature a little exceeding 100° C. until all the water was expelled. The resulting mass was powdered and exhausted with absolute ether, which removed a substance which imparted a vivid green tinge to the flame. This substance was soluble in absolute alcohol and also in water; this latter solution was strongly acid and contained a sugar which reduced Fehling's solution. Strained honey was found to be slightly acid; this acidity was neutralized by the addition of sodium carbonate. The faintly alkaline honey thus obtained was added to a solution of borax, which is also alkaline; an acid reaction ensued, which was destroyed by heat, the solution becoming alkaline but regaining the acidity on cooling. The liquid gave no green flame reaction. A saturated solution of borax was mixed with faintly alkaline honey until acidity was strongly developed and slight excess of honey had been added. No green flame reaction could be obtained with the solution, although a great number of trials were made. The solution was evaporated to dryness until all the water had been expelled. The mass so obtained was not acid in reaction, neither did it become so upon the addition of absolute alcohol; contrariwise the addition of a small quantity of water caused the development of a marked acid reaction. The mass gave no flame reaction for boric acid. After powdering, it was extracted with absolute alcohol, which upon evaporation left a residue consisting of some unaltered honey together with a body which apparently gave a green flame reaction, although the colour was much masked by the honey present. Another portion of the mass was exhausted with ether, which extracted a substance giving a vivid green tinge to the flame of a Bunsen lamp. It dissolved readily in absolute alcohol and this solution was only faintly acid. The substance readily dissolved in water yielding a strongly acid solution, the acidity of which was unaltered by boiling. The aqueous solution readily reduced Fehling's solution. The mass after extraction was found to contain sodium metaborate. These results agree precisely with those predicted from previous observation of the action of dextrose and levulose upon borax. Thus the acidity of mel boracis is due to boric acid which has been produced by the action of the dextrose and levulose contained in the honey upon borax in presence of water. Mel boracis also contains sodium metaborate.

Elucidation of a Secondary Reaction.—I have previously shown (*Pharm. Journ.*, [3], xiii., 257) that it is a property characteristic of polyhydric alcohols to render a solution of sodium pyroborate, which is normally alkaline, acid in reaction, the original alkalinity being restored upon heating. Since that time I have had the opportunity of trying this reaction with some pure glycocine (prepared by Mr. T. S. Dymond), a substance which resembles dextrose and allied carbohydrates in its principal properties. This substance, unlike dextrose, did not yield the reaction with sodium pyroborate, in accordance with the prevision from the fact that it is not a polyhydric alcohol but amidoacetic acid (CH_2NH_2COOH).

This altogether interesting and anomalous behaviour of the polyhydric alcohols towards a solution of sodium pyroborate, I am now, after having made clear the general nature of their action upon this substance, able to explain. The experiments now described show that these alcohols in presence of water liberate boric acid from sodium pyroborate, sodium metaborate being at the same time produced. It seemed probable that this characteristic behaviour was in reality due to a secondary reaction occurring between the free boric acid and the sodium metaborate and was in no way directly affected by the presence of polyhydric alcohol. Subsequent experiment has completely confirmed this conjecture. The pure sodium metaborate ($NaBO_2$), the aqueous solution of which is alkaline, was very faintly acidified by the addition of boric acid; this solution as it was slowly raised to the boiling point gradually regained its alkalinity, which again disappeared as the liquid became cool, the indications being observed with the aid of phenol phthalein.

The addition of large excess of water produced an effect similar to that of heat. These same phenomena are observed when sodium pyroborate, the aqueous solution of which is likewise alkaline, is substituted for sodium metaborate and when other acids are employed in the place of boric acid. Let a solution of sodium pyroborate be made neutral or faintly acid with boric or with hydrochloric acid and the alkalinity is reproduced by heating but is again destroyed as the temperature of the solution is lowered. Water also is able to annihilate the acidity and reproduce the alkalinity of the liquid. Now when sodium metaborate or pyroborate is dissolved in water dissociation occurs, resulting in the formation of an acid borate or boric acid and the liberation of free alkali;* hence the alkalinity of such solutions. Upon adding acid in sufficient quantity to neutralize this alkalinity, a stable neutral system is the result. The addition of more water disturbs this system of neutrality, by producing further dissociation of the salt indicated by renewed alkalinity. A rise of temperature produces in this neutral solution the same effect as excess of water, namely, alkalinity, which, however, disappears as the solution cools, the heated water effecting dissociation, and recombination occurring as the liquid cools.

If excess of acid be added no change is observed upon heating, doubtless because acid, and therefore more stable, salts are produced. It follows from these experiments that when a polyhydric alcohol is added to an aqueous solution of sodium pyroborate in quantity just sufficient to produce an acid reaction due, as we have previously seen, to the liberation of

* Berthelot has shown (*Essai de Mécanique Chimique*, vol. ii., 225) that increased addition of water produces increased dissociation; thus when boron trioxide combines with sodium oxide to form sodium metaborate ($B_2O_3+Na_2O$) in presence of 220 molecules of water, 11·75 heat units are liberated.

$B_2O_3+Na_2O$ in presence of 330 H_2O liberates 11·56 h.u.
$B_2O_3+Na_2O$ in presence of 440 H_2O liberates 11·13 h.u.
$B_2O_3+Na_2O$ in presence of 1320 H_2O liberates 10·91 h.u.

boric acid from some of the sodium pyroborate with formation of sodium metaborate, upon the addition of more water or application of heat dissociation of the undecomposed sodium pyroborate and metaborate takes place, liberating alkali in quantity more than sufficient to neutralize the free acid, hence the liquid is alkaline. As the temperature is lowered recombination takes place with the consequent regeneration of the original neutrality or faint acidity. If excess of the polyhydric alcohol be added, that is, more than enough to render the liquid neutral or faintly acid no reaction is produced upon heating, evidently because excess of boric acid has been set free.

General Considerations.—The chief result of this inquiry is to show that polyhydric alcohols decompose sodium pyroborate with the formation of sodium metaborate and a boric ether or, if water be present, free boric acid. There are no doubt many secondary reactions involved; in fact, one such reaction has just been under discussion. The principal properties of these bodies have been described, but whether they are mono-, di-, or tri-borins, has not directly been determined. In the case of glycerol, however, there can be little doubt that the substance produced is glycerol in which all the three hydroxyl groups are substituted by the boric radical ($C_3H_5BO_3$). The following equations symbolize the action of glycerol upon sodium pyroborate and similarly other polyhydric alcohols:—

$$2C_3H_5(OH)_3 + (2NaBO_2.B_2O_3) = 2C_3H_5BO_3 + 3H_2O + 2NaBO_2.$$

But inasmuch as water itself is a product of the decomposition, the above reaction is never complete save at high temperatures, owing to the conversion or partial conversion of the borin into boric acid under the influence of the water, thus*—

$$C_3H_5BO_3 + 3H_2O = C_3H_5(OH)_3 + H_3BO_3.$$

In aqueous solutions the reaction may be thus represented in one equation—

$$2C_3H_5(OH)_3 + (2NaBO_2,B_2O_3) + 3H_2O = 2NaBO_2 + 2H_3BO_3 + 2C_3H_5(OH)_3.$$

This is a reaction, which, taken by itself, might be attributed to what has been called "catalysis," for the glycerin remains unchanged at the close of the reaction. It is, however, now manifest that the production of a boric ether is the determining cause of this reaction, which is thus brought under the category of chemical action and the use of a fictitious explanation, if at any time legitimate, is here rendered superfluous.

Not only are the results of this investigation interesting on the side of the polyhydric alcohols but also as additional evidence in favour of regarding anhydrous borax as a sodium pyroborate; that is, a compound of boric anhydride with sodium metaborate.

PERFUMES AND ESSENTIAL OILS.

A NEW MODE OF EXTRACTION BY MEANS OF VACUUM AND COLD.†

BY LAURENT NAUDIN.

This communication has for its principal object the description of a new mode of extraction of essences and perfumes by volatile solvents with the aid of vacuum and cold.

The collection and preparation of odorous substances date back to the most remote periods of historical tradition. Perfumes have, in short, from the earliest ages occupied a prominent place in the religious services of the most diverse nations, and even in the present day incense is burnt in the ceremonies of many creeds. The etymology of the word perfume alone—*per fumum*, by smoke—shows the manner in which the substance it designates was used, and that the art of combining delicate and refreshing odours, or more properly the art of the modern perfumer, originated in the ancient custom of burning incense on the altar.

This art has been handed down during several centuries without any great modifications. Thus the processes for the extraction of essential oils and the preparation of waters and scented oils that were used in India and by the Arabs are the same as those carried on in the laboratory of the modern perfumer. Mechanical improvements have aided in perfecting the apparatus, which, however, is not very complicated. Progress has been made, not in the extraction of the rich and varied perfumes of nature, but solely in the compounding of mixtures of perfumes. Indeed, it is curious to read in ancient writings textual descriptions of the principles upon which the processes still employed in the current manufacture of perfumes are based.

Lenormand, in his 'Traité de la Distillation,' states expressly that the Arabs have from time immemorial effected the extraction of the aromatic parts of plants by distillation. These people in their incursions into Europe introduced their processes successively into Italy, Spain and France. But in France this industry was localized first in the department of Hérault, from which it has almost completely departed to settle in Provence, under the beautiful climate of the Alpes-Maritimes. Algeria commenced to send her products into the market, but owing to the absence of any systematic cultivation of flowers, the perfume industry in this French colony has nearly died out. Thirty years ago, Millon called the attention of perfumers to the immense resources of Algeria, but his urgent appeal, though justified by the richness of the Algerian vegetation, was not listened to.

At present essential oils and perfumes are obtained industrially by distillation, hot and cold enfleurage, and expression.

The mode of extraction by distillation with steam consists in placing the odoriferous vegetable substances (flowers, seeds, wood, roots, etc.), together with a certain quantity of water in an ordinary still, and heating to the boiling point. Under the influence of this temperature (100°), the plant cells are ruptured, and the essential oil carried over mechanically by the steam is condensed with it in a cooled receiver and separated in an oily form. Formerly the heat was applied by a naked fire, but the essential oil then acquired a very marked empyreumatic flavour; recently the use of steam has replaced this barbarous way of applying heat.

There are two great objections to this mode of proceeding: the destruction of a part of the perfume, owing to the high temperature that is necessary, and the great modification sustained by the undestroyed portion of the perfume from contact with the steam. Consequently the essential oils obtained by this mode never contain the perfume of the flower in all its perfection, but inevitably possess an odour, known to perfumers and distillers as the "flavour of the still." The quantity of perfume destroyed by the steam may amount in certain cases to as much as 50 per cent.

In the hot enfleurage the flowers are digested for a sufficient time in oil heated in a water-bath. When exhausted, they are withdrawn from the oil and submitted to a strong pressure in order to recover the fatty matter with which they are saturated. To the inconveniences enumerated when speaking of distillation, the following may be added: (1) the loss of the fat remaining in the cake of flowers submitted to pressure; and (2) the rancidification of the fatty matter when heated to a high tempera-

† Abstract of a paper in the *Moniteur Scientifique.*

ture. It is known in practice that the glycerides heated to 100° C. acquire a rancid flavour.

Cold enfleurage is adopted in the case of the more instable perfumes, which are destroyed by heat, rendering it necessary to impregnate the oily body at a low temperature. For this purpose the flowers are laid in contact with a linen cloth saturated with oil or on a glass tray having a layer of oil spread over the bottom. The flowers are renewed at intervals of twenty-four hours. One inconvenience of this primitive method is the rapid rancidifying of the oily matter under the influence of a partial fermentation of the flowers and of the humid temperature of the climate in which it is necessary to carry on these operations, and the consequent alteration of the perfume. It may be mentioned that in the flower season, the same oily matter stands, for a month at least, in contact with air at a temperature of 35° to 45° C. Besides this there is the loss of a great part of the perfume, the flowers never being quite exhausted when renewed, as well as the loss of the oily matter left in the flowers. To obviate these inconveniences, it has been proposed to employ glycerine and syrup of sugar in the place of oil and fat in the processes of hot and cold enfleurage. Neither of these bodies are susceptible of rancidity, but the solubility of glycerine in alcohol, and the instability of syrups when exposed to contact with air, have prevented their practical employment.

Several years ago paraffin and vaseline were tried as substitutes for olive oil in hot enfleurage; but paraffin has been abandoned, whilst vaseline yields alcoholic extracts of which the perfume is contaminated with a petroleum odour.

Expression is undoubtedly the best of all the processes at present in use. It is applied, however, only to a limited class of oils: those of the lemon, bergamot, orange, cedrat (*Citrus medica*) and lime (*C. Limetta*). The products derived in this way from the rind of these members of the genus Citrus, are incomparably superior to those obtained by distillation or enfleurage.

In 1835, Robiquet described the preparation of the delicate perfume of jonquil by means of ether, but the process was not then carried out industrially. Two years after, Buchner, in a note on "L'Arome de quelques Fleurs," expressed the idea that practical application might be made of Robiquet's method. Afterwards, Millon, the principal of the central chemical laboratory in Algiers, in an able memorandum on the nature of the perfume of flowers and on some flowers that might be cultivated in Algeria, mentioned a series of experiments as to the employment of volatile solvents in the extraction of perfumes of flowers. The solvents were chloroform, carbon bisulphide, ether, methylic alcohol, vinic alcohol, etc.; but he distinctly gave the preference to ether. His co-worker, Ferrand, took out a patent with this object in which he described the mode of working. It consisted in introducing the flowers into a displacement apparatus, covering them with ether, and allowing the liquid to run after being in contact for about ten minutes. The ether was evaporated in an ordinary distilling apparatus, the perfume being left as residue.

Apparently Millon and Ferrand had no knowledge of Robiquet's experiments twenty years before, but however this may be the results announced by Millon were important. Trials were made on a large scale, but it was nevertheless found necessary to abandon this process on account of the danger of using large quantities of ether in open vessels and the loss of a considerable quantity of the solvent in each operation, through it being impossible to drive off the last traces of it from the perfume. Dr. Quesneville, as early as 1857, had perceived and pointed out the moderate practical value of the process. Since that time, however, new attempts have been made in the same direction, some of which are worthy of notice.

An industrial experiment of Lemettars and Bonnière, of Rouen, had for its object the extraction of the perfume from dry species and fresh plants by carbon bisulphide rectified by treatment with alkalies and lead salts.

Deiss, of Marseilles, introduced a system of purification of perfumes extracted by carbon bisulphide. In his patent, Deiss stated that the employment of carbon bisulphide, easily decomposed by the water contained in fresh flowers, communicated a sulphurous odour to the perfumes. He therefore proposed to wash the perfumes with an alkaline solution or a solution of monosulphide of sodium for the purpose of removing chemically the solvent retained mechanically by the perfume mixed with the wax of the flowers. Considering the extreme alterability of certain perfumes by alkalies, this idea was hardly a happy one.

Then came the experiments of G. Ville with chloroform and De Hirtzel with the light petroleums. Neither of these modifications of Millon's method was, however, able to stand a practical test.

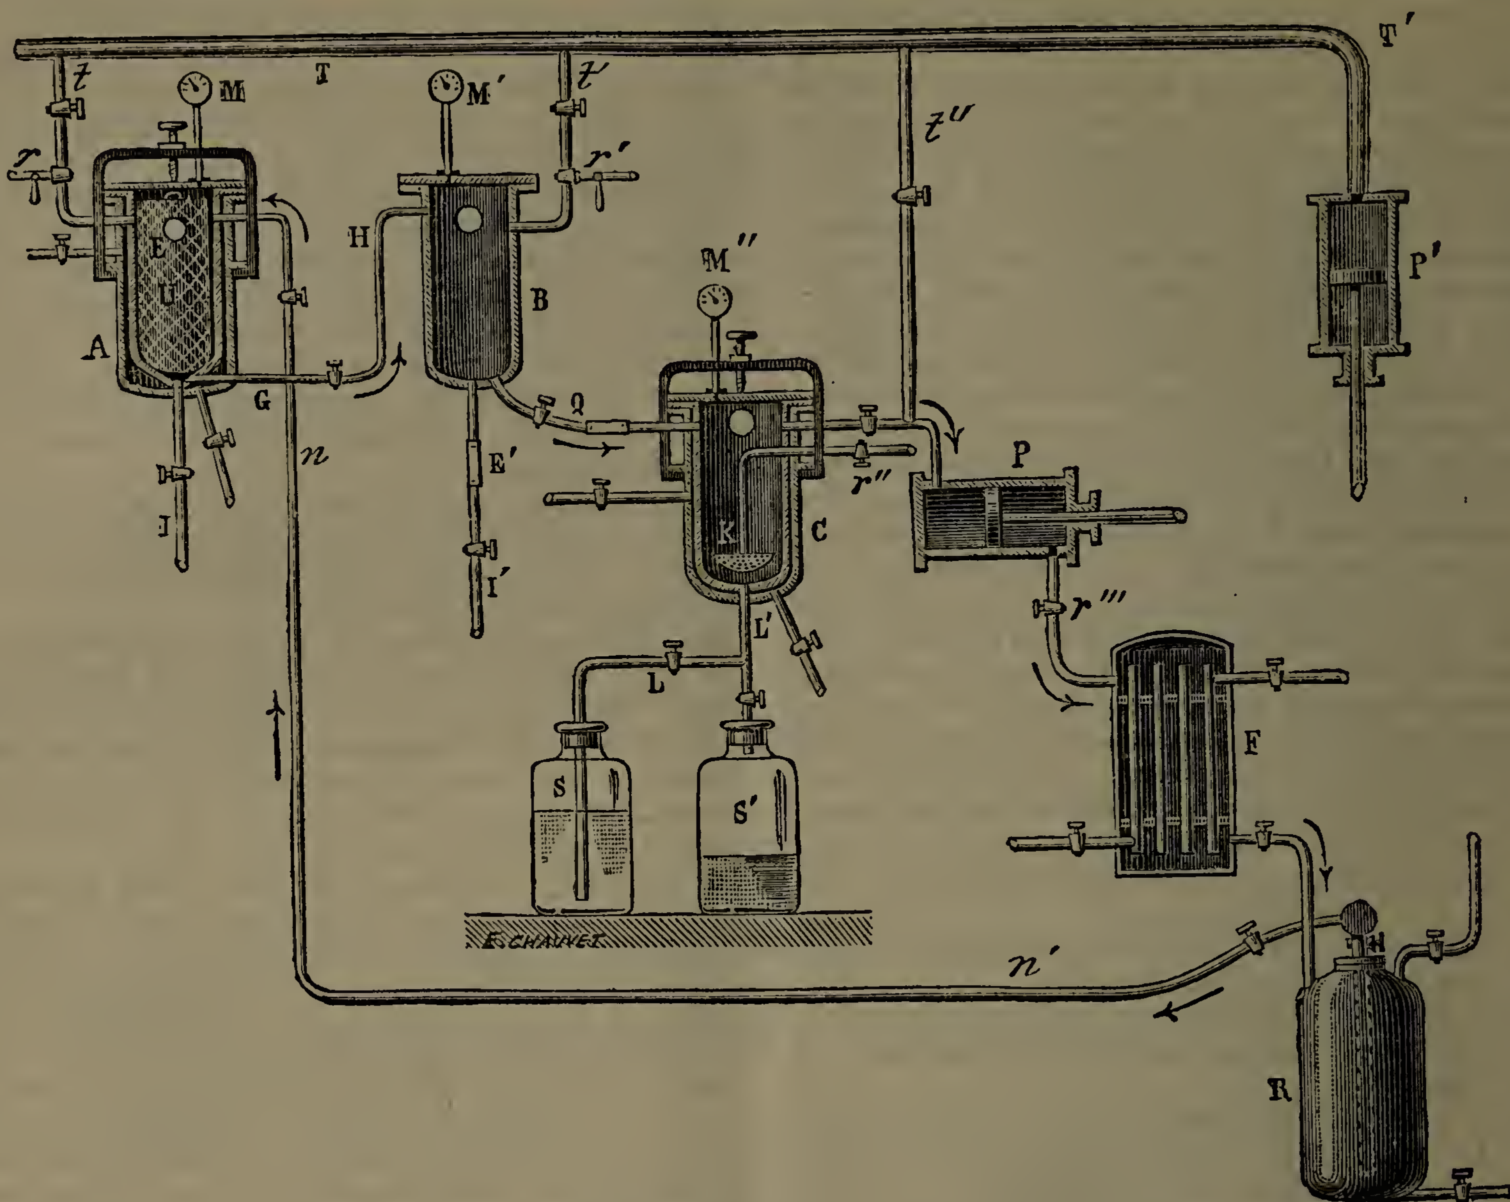
The official reports of the Exhibitions of 1862 and 1867 show that the question of solvents had not yet been solved. The reporter at the Exhibition of 1878 mentioned as the only improvement worthy of notice the substitution of steam for the naked flame in the heating of vessels; no mention was made of the industrial employment of volatile solvents.

It is only just, however, to notice the persevering efforts of Piver to replace the ordinary process of enfleurage by what he called the pneumatic method. Piver also proposed in 1862 the washing of the perfumes extracted with carbon bisulphide with an alkaline solution, an idea that had already been patented by Deiss.

This rapid *résumé* will show that the use of volatile solvents had not been rendered practical, because: (1) owing to the work being done in open vessels there was a great danger of fire and serious accidents; (2) the loss of the solvent was not less than 10 per cent. each treatment; (3) for the purpose of entirely getting rid of the solvent it was necessary to raise the temperature considerably and in doing this the perfume was sensibly altered. Therefore, notwithstanding the incontestible truth of the principle discovered by Robiquet, this method has been practically abandoned.

The author of the present paper, M. Naudin, has been occupied with the study of this question for four years, and has contrived an apparatus by which he seeks to avoid the causes of failure before mentioned. This apparatus, based on the distillation of volatile solvents in closed vessels in a vacuum and at a very low temperature, is composed of the following six elementary parts:—(1) A digester (A) in which the perfume is extracted by contact of the volatile liquid with the odorous substance. Instead of a single digester, a series of vessels can be used, communicating with each other in such a manner as to allow of a systematic exhaustion being carried on. (2) A decanting vessel (B) in which the perfumed solution is purified by decantation from the aqueous portion of fresh flowers, removed mechanically during the digestion. (3) An evaporating vessel (C) in which the volatile solvent is distilled off, leaving the perfume as a residue. (4) A suction and forcing-pump (P) for the purpose of hastening both the distillation of the volatile solvent by the aspiration of its vapours, and the condensation and liquefaction of the vapour, by compression in the refrigerator (F), and to collect, at the end of the operation, the traces of the solvent remaining in the different parts of the apparatus and drive them into the refrigerator (F). (5) A cylindrical refrigerator (F) in which the volatile liquid is condensed. This condenser is kept cool by one of the known methods, such as ammonia, sulphuric acid, etc. (6) A receiver (R) in which to store up the solvent employed.

The three vessels A, B, C, and the refrigerator can be hermetically closed by means of joints. The tube T, T′, which is in connection with the whole apparatus, distributes the vacuum caused by the pneumatic pump (P). This tube communicates with the vessels A, B, C, by the



tubes t, t', t'', supplied with taps. Air is readmitted at pleasure by r, r', $r''r'''$, or by means of compressed air, consisting of air removed from the apparatus and forced into a special receiver. The manometers M, M′ M″ indicate at any moment the state of the vacuum in each vessel. The level of the liquid solvent is shown by means of a glass window in each vessel (see E in A). The vessels A and C have each a double lining so as to allow the introduction of air or hot or cold water.

The flowers, leaves, etc., are introduced into the digester (A), and confined in a basket (U). The vessel is closed and a vacuum, obtained by opening the tap (t), causes a suitable quantity of the solvent to ascend from the receiver (R), by the tube n, n'. The materials having been left to digest for about fifteen minutes, the solvent liquid charged with the perfume is passed from A into B, in which a vacuum has been previously made, by connecting A and B by means of the tube G, H, which proceeds from the base of A. The water contained in the flowers is carried over mechanically by the solvent, and accumulates at the bottom of the vessel B, whence it is got rid of by the tube I. A glass window (E) allows the distinct separation of the two liquid layers. Communication being established between the evaporator (C) and the refrigerator (F), a vacuum is established by means of the tube t''; the solvent, charged with perfume and free from water, is then allowed to run from the vessel (B) into the evaporator (C). Communication between B and C is then closed, and the refrigerator (F) cooled energetically, after which the pump (P) is set to work. The vapours of the solvent are drawn from C, and then forced into and rapidly condensed in F. During the distillation, the evaporator (C) is kept at the temperature of the surrounding atmosphere; this is effected by passing a current of water between the double lining, which restores the latent heat borrowed by the volatile solvent upon its conversion into vapour.

When a very energetic source of cold is at disposal, the employment of the pump as a means of liquefaction may be dispensed with. In this case the vapour passes directly from C to F. After complete evaporation a white or coloured residue is found on the sides of the evaporator C, which may be a solid, liquid, oily, or semifluid substance, eventually becoming solid.

When the distillation is finished, the distilled liquid condensed in F is allowed to run into the receiver R. If a sufficiently low temperature has been maintained during the distillation this liquid will not be sensibly tainted with any odour, and may be used in the manufacture of different perfumes. The perfume mixed with the wax of the flowers and leaves, dissolved also by the ether, requires to be separated. For this purpose, a given quantity of alcohol contained in the vessel S is drawn up through the tube L by means of a vacuum into C, and is left there to digest some time. Solution is favoured by the readmittance of air through K, which agitates the mass violently; the liquid is then drawn off into the vessel S, which is kept at a temperature of $-10°$ in order to precipitate the wax, whilst the perfume remains dissolved in the alcohol, and the whole is filtered at the same low temperature. The perfume thus prepared consists of an alcoholic solution.

In the manufacture of perfumed oils or fats, this manipulation with alcohol is not necessary; the perfume, mixed with its natural wax, is dissolved in the oil or lard, which are the vehicles generally employed.

The exhausted flowers in the digester A mechanically retain some of the solvent. To recover this the mass is heated by the introduction of steam into the outer jacket, and the solvent is condensed in a special refrigerator. The employment of a vacuum allows the whole of the solvent to be recovered.

It will be seen from the foregoing description that the movement of the solvent liquids from one vessel to another is effected simply by differences of pressure, and that the volatile liquid circulates in closed vessels in a vacuum, without ever coming into contact with the outer atmosphere while passing from liquid into the gaseous state, or *vice versâ*. The other advantages presented by this apparatus are that there is no danger of fire; the perfume is completely and quickly extracted, however instable it may be; solution is effected in a few hours in an appropriate menstruum (alcohol, oil, grease or glycerine); pure perfumes, containing all the aroma, are obtained, owing to the low temperature maintained during the extraction; the perfumes are condensed in an exceedingly small volume, and in a form which allows them to be kept for an indefinite period; the greater value of the yield from all the perfumes than in the old method; and the use of extremely volatile liquids, amongst which the following have been tried:—

	Boiling point.
Hydride of butyl	0°
Hydride of amyl	30°
Chloride of ethyl	9°
Chloride of methyl	–23°
Light petroleum spirit.	

The choice of a solvent for a particular perfume is not without importance, the delicacy and sweetness of a perfume depending upon the nature and purity of the solvent. This method yields extremely delicate results, and in operating with care the slightest variation in nature may be reproduced with extraordinary fidelity.

Commaille reports that the separation of the odour of the milk of the cow has enabled Millon as well as himself, to recognize certain plants eaten by these animals, the *Smyrnium Olusatrum* amongst others. M. Naudin has made a series of experiments which show what accuracy can be obtained in this direction. By using a mixture of hydride of butyl and amyl as a solvent he has been able to distinguish clearly and isolate the perfume of roasted coffee from different sources. He obtained a similar result with the fine shades of quality in tea. He also gives instances of isolating and fixing different special odours, as toasted bread, the human skin, raw or cooked food, earths, etc.

The time of collection of the flower is very important. Each flower must be gathered at an appropriate time of the day, and in a certain degree of bloom which experience alone can recognize. Thus the pink only yields its perfume when collected two or three hours after being exposed to sunlight. On the contrary, roses must be gathered in the morning as soon as they are well open. The flower of the jasmine ought to be picked a few minutes after the first exposure to sunlight. The false acacia always gives a fragrant perfume, but differing according as the flower is gathered in the morning, in the evening, or even in the middle of the day.

In distillation, as Millon has already remarked, all the modifications of the flower are mixed in one and the same essence, which does not resemble any of them exactly; but probably the mixture corrects, up to a certain point, the defective parts of the collection. In the new mode of extraction, the slightest alteration, the least variation in the state or quality of the flowers, is revealed in a perfume; to obtain, therefore, a perfume possessing all the freshness and fragrancy of the flowers it is necessary that the flowers used be fresh and fragrant.

The perfumes obtained by the solvent method, instead of dissipating like ordinary essences, are marked by a great permanence. In fact, perfumes become altered by contact with other principles of the plant, which involve them in their own decomposition; but when once isolated from the destructible organs of the plant, the perfumes escape their influence, and obey their own laws of transformation or decomposition.

Millon states that he has kept isolated perfumes for several years in open capsules or tubes, without finding any sensible loss. M. Naudin also has experimented on perfumes that have been in his possession four years. The experiments were at first limited to flowers gathered under the climate of Paris, such as the pink, narcissus, violet, rose, lilac, hyacinth, the lily of the valley, etc.; but have since been extended to the flowers of Cannes, such as the orange, rose, jasmin, false acacia and tuberose. All the perfumes obtained from these flowers have remained unaltered even in contact with air.

As already stated, the perfume, although it remains unaltered in the presence of the oxygen of the air, becomes involved in the general decomposition if left in the presence of the decaying organism of the flower from which it was derived. Now the decomposition of certain flowers when plucked from the plant is extremely rapid; it is therefore obvious that when the apparatus for extraction is at a distance from the place of collection, the perfume obtained does not exactly resemble that of the flower, even when extracted by the solvent method. Thus, it is known that the essence of neroli manufactured at Cannes, the centre of floral cultivation in the Alpes-Maritimes, is superior to that made at Grasse, about ten miles distant. The reason is that some time is necessarily lost between the moment of gathering and the time of manipulation; besides this, there is the transport of flowers in the hottest days of summer, the effect of which is manifest in the diminution of the yield.

The above inconvenience can be met by keeping the fresh flowers in a special vessel, void of air and full of vapour of the solvent, as of ether. The presence of the latter body and the absence of oxygen prevent fermentation, especially if the temperature be kept sufficiently low. The perfume of the orange has thus been kept in its intensity with the flower itself for a month. A manufacturer could thus preserve his materials from fermentation upon the days when the great abundance of flowers—sometimes 20,000 to 30,000 kilograms—would render his digesters of insufficient size to treat the whole at the same time.

The chemical nature of perfumes has been studied by Millon. He recognizes two classes, the essential oils and the perfumes, properly so called. His experiments led him to the conclusion that the extremely small quantity of these bodies contained in the flowers renders their chemical study difficult, if not impossible. In a great number of cases only a milligram of pure product can be obtained from a kilogram. He is of opinion that the perfume of flowers is a fixed or rarely volatile principle, remaining unchanged in air and contained in the flower in only imponderable traces. It is decomposable by heat when the temperature is raised above the ordinary limits of the atmosphere, but is nearly always volatile without apparent decomposition in alcohol, ether, oily bodies and a great number of liquids such as carbon bisulphide, chloroform, benzine, etc. The perfume is nearly indefinitely diffusible in air, that is to say, it vaporizes and denotes its presence there by a fragrant odour, but does not suffer a sensible loss of weight. It is equally diffusible in water, to which a beautiful aroma can be imparted by the addition of a few drops of an alcoholic solution of perfume.

As already mentioned, Millon makes a distinction between essential oils and perfumes. M. Naudin thinks this may be correct as long as the term essential oil is confined to those of which the odour forms an integral part of the properties of the body, such as the oil of wintergreen or salicylate of methyl. Most of the oils with well-defined chemical functions (alcohol, phenol, ether, etc.), may be entered in this class, but the oils of the genus Citrus and of the labiates cannot be included in the broad definition which Millon gives. He also believes that in many cases the isomeric hydrocarbons of the group C_nH_{2n-4} are probably only the substratum of the perfume. A very simple experiment tends to prove this. If the oils of lemon, bergamot, orange, lime (*C. Limetta*) and cedrat (*C. medica*) be boiled for a short time with a slight trace of caustic soda, the odour peculiar to each oil will be replaced by a common odour similar to that of terpene $C_{10}H_{16}$. Indeed the energetic action of caustic alkalies is not necessary to destroy these odours, since light alone, aided by time, has enough influence over these oils to change their special odour into that of oil of turpentine. Oil of angelica, obtained from an umbelliferous plant, gives a $C_{10}H_{16}$ carbide, terebangeline, with an odour of hops, and possessing the same organoleptic character.

Further than this, these general considerations on perfume can be applied to the special odour of fatty oils. No attempt has yet been made to isolate the perfume dissolved in the glycerides, but no doubt it would reveal the same fact, the solution of a very minute quantity of a very odorous and strongly-flavoured body in an inodorous or nearly inodorous vehicle.

Perfumes have not yet been chemically classified; their organoleptic character alone has served to distinguish them, through want of a more intimate knowledge of them. The question therefore remains very obscure; but M. Naudin is sanguine that this new mode of extraction, by putting uncontaminated substances within the reach of chemists will allow of deeper research into their nature. In any case he believes that therapeutics will find, in pure perfumes, a new field of research and will perhaps discover the means of applying them as medicaments.

NOTE ON THE MANUFACTURE OF PHOSPHORIC ACID AS RECOMMENDED BY PROFESSOR W. T. WENZELL.*

BY PROFESSOR E. W. RUNYON.

At the last meeting of the American Pharmaceutical Association, Professor Wenzell presented a paper† containing the observations and experiments he had made in the preparing of phosphoric acid by aerial oxidation. From the published reports of that meeting, it seems that but little discussion took place on the subject. It was spoken of as a very old process, and one not likely to be of practical importance. The writer having made several thousand pounds of phosphoric acid, direct from phosphorus, and having for six or seven years followed the valuable suggestions of Professor Markoe in his paper to the American Pharmaceutical Association, in 1875, was very much interested in the paper of Professor Wenzell on this subject. At his request, some weeks ago, I entered upon a series of experiments, to determine the practicability of the process for the manufacture of phosphoric acid in large quantities.

For this purpose I made use of a square, stoneware crystallizing pan, such as are made by R. C. Remmey and Co., Philadelphia, which holds five gallons. For the bottom of this I had made a vulcanite diaphragm resting on supports of the same material; the slats of this tray were 1 inch wide and placed about an eighth of an inch apart. The sticks of phosphorus rest in the divisions so as to prevent their rolling against each other, should the apparatus be jarred. A porous cover was made of plaster of paris, and ½ or 2 inches thick, and sufficiently large to extend about 1 inch over the four sides of the crystallizing pan. This plaster cast was quite thick and heavy, necessarily so, on account of the large size of the pan —17 × 21 inches. It required several days for the plaster cover to dry with the temperature of the drying closet at 130° F. The cover was then levelled off by passing it over medium coarse sandpaper, tacked on a table. The top edges of the stoneware pan were perfectly levelled, by means of a sheet iron plate, and fine emery, with a little water. It is necessary for the cover to fit perfectly and evenly on all sides of the pan, and for this reason, both cover and pan should be ground.

By means of an auger or bit, an inch hole is bored in the plaster cover, and a cork inserted, through which a thermometer is passed, to record the temperature during the process of oxidation. The apparatus is now complete.

The vulcanite shelf was placed in the bottom of the pan, and distilled water was poured into the pan, until the shelf or diaphragm was barely immersed. The one-eighth inch spaces between the slats of the shelf were then covered with sticks of phosphorus, and the surface of the water brought up to about half the diameter of the sticks of phosphorus. If it be found that there is too much water after the shelf has been covered, it can easily be siphoned off with rubber tubing. The cover of plaster of paris is now placed on, and the apparatus is to be undisturbed for two or three days. At the expiration of that time the cover can be removed for a few moments, without danger of the phosphorus taking fire, and it will be noticed, as Professor Wenzell states, that the acid water has increased in bulk. By means of glass and rubber tubes, sufficient of the acid is drawn off to again partially expose the oxidized sticks.

The cover was replaced and the operation was allowed to continue for three or four more days, when a second portion was drawn off for the last time.

The time for the complete oxidation was about thirteen days, and the time and attention it required during that period did not exceed as many minutes.

The most important and practical feature in the making of phosphoric acid by this process over all the other processes which I have used, is the ready removal of the arsenic with which commercial phosphorus is universally contaminated. Professor Markoe, and others, who have made large quantities of phosphoric acid, give no other way of removing arsenic from phosphoric acid than by passing sulphuretted hydrogen gas through the diluted acid ; and my experience has been, that it is exceedingly troublesome to thoroughly remove it in this way ; the small percentage present (one-sixth to one-quarter of 1 per cent.) seems hardly worth so much trouble. Even after standing a week or more, traces of arsenic sulphide will be precipitated along with some sulphur. Wittstein, in his valuable little book, says: "If, after saturating with the gas, and allowing the solution to stand some days, a yellow deposit is formed, it must be filtered. The acid cannot yet be considered pure, but must again be treated with sulphuretted hydrogen, and is only to be looked on as pure when this treatment no longer causes a precipitate of sulphuret of arsenic. To arrive at this point I found it necessary to treat the phosphoric acid four times with sulphuretted hydrogen."

Our Pharmacopœia calls for a preparation free from any trace of arsenic. Now, by Professor Wenzell's process, all the arsenic is separated (owing to the presence of phosphorous acid) by simply heating the acid solution as it comes from the aerial oxidation pan to a given temperature for a short time. Professor Wenzell states that at a temperature of 160° C., the separation of the arsenic as a brownish-black substance is complete. In the manufacture of several hundred pounds by this process, I have not found this to be the case; true, at 160° C. the liquid was of a dirty black colour, of garlicky odour, owing to the reduction of the arsenic to the metallic state; but when diluted and filtered, it still showed traces of arsenic with hydrogen sulphide.

I find it necessary to heat the acid to 190° C. and 200° C., or to the temperature at which hydrogen phosphide commences to be given off with slight explosions, and keep it a little below this (190° C.) for thirty minutes or more. When at this degree of concentration and temperature, an exceedingly penetrating, disagreeable garlic odour is given off, and the operation should be conducted in a fume chamber.

The acid solution now has a specific gravity of 1·75, equal to about 89 per cent. H_3PO_4. It is diluted with an equal bulk of distilled water, filtered through double, white filtering paper, and then oxidized with nitric acid. The acid solution has a strong, disagreeable odour of hydrogen phosphide, which is entirely removed during the oxidation of the phosphorous acid.

---

* From the 'Proceedings of the California Pharmaceutical Society and College of Pharmacy,' 1883, p. 30.

† See before, p. 24.

Finally, the only deviation the writer has made in the manipulation given by Professor Wenzell is that of carrying the temperature to 190° to 200° C., or until hydrogen phosphide begins to be given off. One of the concomitants of that temperature is the decomposition of a portion of the phosphorous acid into phosphoric acid and hydrogen phosphide. There are other interesting features relating to this process, both in respect to time, economy, and material, in which it has given better satisfaction than some other processes employed by the writer, and to which he may refer at some future time. In oxidizing with nitric acid, care should be taken to have a sufficiently large dish, and not to have the temperature of the phosphoric acid solution above 125° C. on the addition of the first portions of the nitric acid, else a portion of the acid will be lost by the sudden disengagement of the nitric oxide. The reaction commences at 118° to 120° C. and the temperature gradually rises to 140° C. The operation of oxidizing with nitric acid was reversed by pouring the phosphoric acid solution into the heated nitric acid, but without success.

CHEMISTRY THE NYMPHÆÆ.*

BY W. GRÜNING.

Amongst popular remedies in Germany, *Nymphæa alba* and *Nuphar luteum* have long occupied a prominent place, but were omitted from the officinal list of medicinal plants in the beginning of the present century; they have since attracted the attention of chemists on account of their tannin, as a probable substitute for other tanning materials.

Morin, in 1821, published an examination of the rhizome of *N. alba*, and Dragendorff, in 1879, described an alkaloid obtained from it. He promised further researches; but did not carry them out. The author undertook their examination at his request, and made both qualitative and quantitative estimations of the constituents of different portions of the two species, *N. alba* and *Nuphar luteum.*

Moisture and Ash.—Seeds and stalks dried at 110°, and the residue ignited; *N. luteum* showed a richness in alkali which, calculated from sulphates, equals Na_2O, 4·63 per cent., and K_2O, 32·15 per cent.

Fat and Resin.—The former, obtained by treating the pulverized substance with light petroleum, was greenish in colour and thick, easily saponified with soda. The seeds of *N. luteum* yielded a fat, congealing at the ordinary temperature, melting on the hand, and transparent when cold; the resin is the residue of the fat operation treated with ether; in the case of nuphar an intermediate washing with water is given to remove the tannin.

Matter soluble in ether should theoretically equal the sum of those soluble in light petroleum and in ether, but in fact there is a difference.

Soluble in Alcohol.—After extraction with absolute alcohol, evaporation, drying, and weighing, the residue was treated with water, a part of the solution again evaporated, the remainder of the aqueous solution was employed for estimation of tannin by Sackur's process—precipitation by copper acetate.

Soluble in Water.—20 grams macerated for one or two days at ordinary temperatures in 400 c.c. water, a part evaporated, dried and weighed, and a part precipitated with alcohol, the precipitate dried and ignited—the nitrogen in both estimated by soda-lime; part treated with lead acetate for tannin, and freed from lead with sulphuretted hydrogen; the remainder was employed to estimate glucose and saccharose. An examination for vegetable acids other than tannin showed the presence of citric, oxalic, and malic acids. Tests for salicylic, tartaric, benzoic, succinic, and fumaric acids yielded negative results.

Soluble in Soda Solution.—Part of the residue from the previous operations was treated with an aqueous solution of 1 per 1000 of soda, filtered, the filtrate neutralized with acetic acid and decomposed with alcohol; the precipitate after deduction of ash was called metarabic acid.

Starch.—The residue from the soda treatment, boiled with water, a small quantity of diastase added, left to digest four hours at a temperature of 40°, filtered, 4 per cent. hydrochloric acid added and boiled in connection with an upright condenser for three hours: the resulting sugar, estimated by Fehling's solution, was calculated to starch.

Pararabin.—The residue, after removal of starch, was digested for a day with 1 per cent. solution of hydrochloric acid, quickly boiled and filtered, the filtrate treated with alcohol, and the precipitate (ash deducted) reckoned as pararabin.

Wood gum of Thomon was sought, but not found.

Cellulose.—After the various processes described, the portions of the plants were treated with freshly prepared chlorine water, and successively with clean water, dilute soda solution, and again fresh water; the loss of dry matter between two weighings, less albuminous matter, was reckoned as lignin and similar substance.

The following table shows the results of the analysis:—

	Nuphar.		Nymphæa.		
	Rhizoma.	Seeds.	Rhizoma.	Roots.	Seeds.
Moisture	10·30	11·31	10·56	6·71	9·06
Ash	5·19	0·89	5·47	10·07	2·12
Fat	0·77	0·51	0 49	0·59	1·06
Resin soluble in ether	0·60	2·11	1·55	1·38	0·21
Resin insoluble and phlobaphene	1·54	1·97	2·52	0·30	0·42
Mucous matter with traces of albumin	1·31	0·26	3·62	6·94	1·47
Tannin	2·27	0·72	10·04	8 73	1·10
Matter not precipitated by copper acetate	0·54	—	0·03	1·00	0·86
Glucose	5·93	—	6·25	5·62	0·94
Saccharose	1·21	—	—	—	—
Substances soluble in water indirectly estimated	4·40	1·38	1·92	3·60	1·18
Metarabin, etc.	2·50	0 86	3·26	6·11	0·46
Soluble in dilute soda solution not precipitated by alcohol	8·36	0·59	5·80	3·60	1·51
Starch	18·70	44·00	20·18	4·09	47·09
Pararabin	3·81	—	1·80	1·20	—
Albumin	3·99	7·08	4·06	7·21	9·79
Lignin, etc.	14·82	6·45	14·26	8·99	4·78
Intercellular substance	—	3·22	—	2·47	0·98
Cellulose	14·11	13·21	9·36	17·42	11·66

Alkaloids,—The author succeeded in separating an alkaloid from *N. luteum*, and also from *N. alba.* Dragendorff had already isolated it in the case of the latter. The chemical and physical properties appear to be identical as well as their behaviour towards group reagents, but in their colour reactions there is a decided difference; *Nupharine*, as the alkaloid of *N. luteum* is named by the author, is a whitish, brittle mass, which on being rubbed sticks to the fingers. It solidifies at 40° to 45°; at 65° it is of a syrupy consistence; it is easily soluble in alcohol, chloroform, ether, amyl alcohol, acetone, and in dilute acids, but almost insoluble in light petroleum; the acid solution has a peculiar and characteristic smell, and is acted on by most of the group reagents for alkaloids, potassium chromate, picric acid, iodide of potassium. etc. With trouble the author discovered colour reactions which distinguish it from all other alkaloids. A small quantity when dissolved in dilute sulphuric acid and warmed on a steam-bath, assumes a brown colour, which gradually passes into a dark black-green; the addition of a very few drops of water causes the colour to disappear, with precipitation of a voluminous yellow-brown substance. The acid solution when placed over sulphuric acid and lime, after ten or twelve days, becomes a magnificent green, increasing in intensity for

* From *Arch. Pharm.*, [3], xx., 582–605, and 736–761. Reprinted from the *Journal of the Chemical Society.*

about another ten days, until it becomes a dark blue-green; a few drops of water causes the colour to disappear immediately with separation of a yellow crystalline precipitate, which when removed from the filtrate, liquefies in air, or over sulphuric acid, with return of the green colour. This experiment can be repeated frequently with the same sample.

The alkaloid is tasteless, but its acid solution is intensely bitter; it has not yet been obtained crystalline.

The formula given to the alkaloid is $N_2C_{18}H_{24}O_2$. The formula requires an equivalent of 300; by experiment it was found 285·5; the differences are attributed to impurities in the sample.

The same formula has been given by Pelletier and Couerbe to menispermine and paramenispermine; the three alkaloids are probably isomeric. With Wild's polariscope nupharine is optically inactive. Its physiological effects were tried on cats, with no toxic effect.

The alkaloid of *Nymphæa alba* does not give the green reaction with dilute sulphuric acid, but on the contrary, it gives the following, which are not given by nupharine. Concentrated sulphuric acid and potassium chromate colour its solution first red-brown, after some hours clear green. Concentrated sulphuric acid alone produces a red-brown, which passes into grey. Frohde's reagent colours first red, then dirty green. The alkaloids are not present in the seeds of *N. luteum* nor in the blossoms or seeds of *N. alba.*

In the second paper the author continues the examination of the two plants of the family, *N. alba* and *Nuphar lutea.* As far as examination of two members of it allows him to come to a conclusion, he thinks that the tannin contained in them is their most important constituent from a chemical point of view; after that the alkaloids and then the starch. The tannins of the two species differ slightly in their properties, but are closely related in their reactions. They both differ from tannin derived from other sources in yielding characteristic secondary products. The insoluble tannin found in them is very characteristic, but a somewhat similar substance was found by Löwe in oak-bark, and as methods of examination are now in use which were not then employed, it is probable that the substance has often escaped detection, and will be more frequently found in future.

The insoluble tannin of oak-bark is the anhydride of the soluble acid; the insoluble acid of Nymphæa appears to be a hydrate of its phlobaphene, and the author thinks it more than probable that the phlobaphene is an intermediate product between the soluble and insoluble tannin.

The tannins of Nymphæa are also notable for yielding many secondary products, which have individually been found in other tannins, but their presence together has not been hitherto noted. Ellagic and gallic acids are easily obtained; another substance, which rapidly absorbs oxygen from the air and passes into a body of the nature of phlobaphene, and a second substance, which by similar absorption of oxygen passes into two bodies, or assumes two phases with properties similar to chlorophyll. Sugar was looked for in consequence of Strecker and others having asserted it to be one of the derived products of tannin from gall-nuts and oak-bark, but it was not found.

The author's experiments lead him to believe that the molecule of the tannin obtained from Nymphæa is of a very complex nature.

GERMS AND EPIDEMICS.

BY JOHN S. BILLINGS.

(*Continued from page* 32.)

You will notice that Pasteur's method of diminishing the virulence of various germs depends largely upon exposing them to the influence of oxygen.

Recently MM. Nocard and Mollereau have reported that this same attenuation can be produced by mixing the virus with oxygenated water, but much more rapidly than by the method of successive cultures (*Bull. Acad. de Med.*, 1883, 2 sec. v., xii., p. 3).

It cannot be said that Pasteur's claim to have established the general rule that inoculation with artificially modified virus will afford protection against the disease is yet to be considered valid. His methods and conclusions have been sharply criticized by Koch, who is certainly a competent judge, and for the present we must suspend judgment. It will probably at once occur to you that vaccine may be in like manner an attenuated virus of small-pox, in fact, Pasteur calls his method vaccination, and it is claimed by some experimenters that true vaccine vesicles have been produced on cows by successive inoculations of virus derived from small-pox. The question is one of much practical importance, but other skilled experimenters have not obtained the same results, and at present the connection is a doubtful one. It has recently been authoritatively announced that Professors Schutz and Loefler, of the Imperial German Board of Health, have discovered the pathogenic organism of glanders, have succeeded in cultivating it to the production of spores, and with the results of these cultures have produced the disease in sound horses, which is the scientific demonstration that the cause is really the organism in question.

Of the specific contagious diseases of man in which micro-organisms have been found, one of the best marked is the so-called relapsing fever, a disease which has been known in Ireland for over a hundred years, being known there by the terribly significant name of the famine fever; and which within the last century has several times spread widely in epidemic form over Europe and this country. In the blood of persons affected by this disease there are found micro-organisms consisting of extremely delicate threads, varying in length from two to six times the breadth of a blood corpuscle, twisted into a spiral or cork-screw shape, and moving about actively. They are found only during the paroxysms of the fever, and disappear during the intervals. When a little blood containing these spirilla is kept at the ordinary temperature of a room, the organisms will live for several days, but if this blood be kept at the temperature of the human body, say 98° F., they will die in about eighteen hours, while if the temperature be raised to fever heat, 104° F., they will survive only about eight hours. Inoculation with blood containing these spirilla causes relapsing fever in a healthy person, but as yet attempts to cultivate the microphyte outside the living body have not been successful, and spore development has not been observed. In form, size and appearance this spirillum is almost identical with a common microphyte found in foul water, and which also has been found in the mouth of a healthy person, but as yet no connection has been traced.

Among the most interesting and practically valuable advances in our knowledge of the relations of micro-organisms to disease in man, are those which relate to the causation of the various disturbances which occur after wounds and injuries, and which are known as septicæmia, pyæmia, erysipelas, wound fever and puerperal fever; all of which, it now seems probable, are due to the action of the microphytes which are concerned in ordinary putrefaction, and which are to be found almost everywhere. They do not exist in the blood and tissues of healthy men, but are present in enormous quantities on the skin and in the mouth and alimentary canal. The precise method in which they cause disease probably varies somewhat in different cases. Sometimes they act mechanically by collecting in heaps and plugging the smaller vessels, but in most cases they do not multiply in the blood so much as in certain limited localities among the tissues to which they gain entrance through wounds, and it is supposed that the inflammation, suppuration and fever which they produce is due not so much to their mere mechanical presence as to a poison which they produce from the fluids which nourish them, somewhat as the yeast plant produces alcohol.

Dr. Ogston, Surgeon to the Aberdeen Royal Infirmary, who has for some time been specially studying this subject, thinks that this poison is one of the ptomaines, a peculiar group of alkaloids which are gradually produced in dead bodies by the process of putrefaction. Attention was first called to these compounds in the examination of dead bodies in cases of suspected poisoning when it was found that the application of chemical tests produced results similar to those which might have been expected if the person had been killed by a vegetable poison; in fact, in one case in Italy, the chemists concluded that a man had been poisoned with delphinium, which they supposed they had found in the body, when in fact it was a ptomaine formed in the body after death. Several years ago it was discovered that a decomposing organic fluid, which produced rapidly fatal septicæmia, when injected into the blood vessels of an animal, might be so filtered by passing it through unglazed porcelain, that all the micro-organisms were removed, and that from the structureless liquid thus prepared there could be obtained by evaporation and extraction with alcohol, a substance capable of producing septicæmia and death. This substance was named sepsin, and the ptomaines appear to be much the same thing. In fact, the accounts of the latter in the reports of the French Academy remind one a little of that worthy and learned professor who discovered that the poems of Homer were not written by Homer but by another man of the same name. These poisons are not themselves capable of growth or reproduction, and it is not certain that they are produced only by microphytes; on the contrary, M. Gautier maintains that he has found them to be common products of the decomposition of our tissues which is a necessary part of life, and that they are found in normal human saliva. If this were true the saliva of a healthy child might be simply one end of scales of virulence of which the others are formed by the slaver of the mad dog or the venom of the cobra. This is, however, not probable, for although human saliva, as contained in many mouths, is very deadly to certain animals, it has been shown that this is due to certain micro-organisms which multiply rapidly in the blood of rabbits and produce death like the germ of chicken cholera, and the virulence of which can be attenuated in the same manner.

The knowledge that the gravest dangers after wounds and surgical operations are due to micro-organisms, which are probably identical with the ordinary bacteria of putrefaction, has led to the careful use of means to destroy the vitality and power for harm of all such organisms which may gain access to wounds. This constitutes what is called antiseptic surgery, and the surgeon now undertakes without hesitation operations which twenty years ago would have been deemed quite unjustifiable, for he knows that by ensuring that neither through the air nor the water, or by the sponges or instruments or fingers, or crevices under the finger nails, there shall be conveyed to the wound one single germ which has not had its powers of growth and reproduction totally destroyed, he need have no fear of blood poisoning. In some of the great hospitals of St. Petersburg, overcrowded and unventilated, where you catch the peculiar hospital odour while you are yet in the street, and in which I was told that twenty years ago an amputation of a finger was considered to be a very serious operation, so certain was it to be followed by erysipelas and suppuration, they now perform the most extensive operations antiseptically with excellent results. Not that the bad condition of the hospital does not produce ill effects, but that these effects are of a very different kind from those which used to appear.

About the end of March, 1882, a new form of fever appeared in Aberdeen, Scotland. A characteristic symptom was a swelling of the glands about the angle of the jaw. In a day or two the fever subsided leaving the patient very weak. Usually there was a relapse two days after, and sometimes there were as many as six of these. There were about three hundred cases and three proved fatal. It was found that all of them had been using milk from a certain dairy, and that the milk from this dairy contained spores, which, when cultivated, produced bacilli. Rats inoculated with these soon died and their tissues were found to be filled with bacilli. Matter taken from one of the sick was found to contain these bacilli, and rats inoculated with this matter died in the same way as the rats infected by the milk. Further investigation showed that the organisms had been added to the milk with water. The observations were made by competent physicians and microscopists and the chain of evidence seems fairly complete. In a communication presented to the Academy of Medicine, December 12, 1882, M. Pasteur states that he has proved that the upper part of the spinal cord of a man or animal dying of hydrophobia is always virulent, and that he has preserved specimens for three weeks which retained their virulence. He also claims to have three or four dogs which having once been inoculated with hydrophobia, and recovered, are no longer susceptible. Unfortunately the great majority of dogs die in the process of rendering them insusceptible. He does not, however, state that he has discovered any micro-organisms peculiar to this disease. With regard to malaria, the latest published researches of importance are those of Professor Ceri. His conclusions are, that it is produced by micro-organisms, the vital properties of which are destroyed by high temperatures and by quinine in the proportion of 1 to 800 of water. They lose their infectious qualities in the animal organism, but may regain them in the soil under favourable conditions. He considers that it is proved that malaria may be carried by human beings into places hitherto free from malaria, although it is not communicable from one man to another (*Philadelphia Medical Times*, Dec. 16, 1882, p. 194).

According to Lind, the first rains which fall in Guinea are considered the most unhealthy, and they have been known in forty-eight hours to make leather quite mouldy and rotten. Mungo Park observes that three minutes after the rain commenced many of the soldiers were affected with vomiting, and others fell asleep and seemed as if intoxicated.

With regard to diphtheria the evidence is not yet satisfactory, but it seems most probable that it is caused by a micro-organism, which occurs also very commonly in a harmless form and becomes virulent under conditions which are not yet understood. I will refer to but one other form of disease which it is claimed is due to vegetable germs, and that is tuberculosis, better known to you in its most common form—consumption. Dr. Koch has announced that this disease is due to minute motionless bacilli, which can be cultivated outside the human body, but require a high temperature and have a very slow growth. The bacilli are found in the sputa of consumptive patients, and such sputa will produce the disease in animals, nor do they lose their virulence by dying, at least for the period of eight weeks. This tenacity probably depends on the spores, which are formed in the body and not out of it, this being contrary to the habit of *Bacillus anthracis*. Koch produced the disease in animals by inoculation of his culture products; but in the animals chosen for his experiments tubercle is caused sometimes by inoculation of matters which are not tuberculous. This reminds one of an objection made several years ago in the French Academy of Medicine to a report of a somewhat similar series of inoculation experiments. Professor Gubler said they were not conclusive because they had been performed on rabbits, and "the rabbit is a melancholy animal to whom life is a burden and who only asks to leave it." The contagiousness of consumption has long been a disputed point, although the opinion has been growing among medical men that it is sometimes communicated, and statistics contribute a curious bit of evidence in this direction. It is found that of the widows of men dying of consumption the proportion dying of the same disease is larger than it is among widows of men dying of other diseases. Upon the whole, the connection of consumption with a bacillus is still doubtful, though not improbable, and the same may be said with regard to malaria; meaning by this much-abused word the specific cause of intermittent fever.

The bacillus of leprosy was discovered by Dr. Hansen, of Norway, in 1874, and has been confirmed by numerous investigations. Dr. White, of Boston, a most competent authority, remarks of this disease, that "its origin is older than history, and it does not appear to have changed for ages. It prevails over large portions of the earth's surface, and we have at present three centres of it in the United States—one in Louisiana, another in the North West, and a third on the Pacific coast, affecting three entirely distinct nationalities, in different climates and under quite diverse methods of life." He believes there is danger of its spread, and that it should be controlled by isolation and by the prohibition of the immigration of lepers. The danger is no doubt small—that is to say, there is a very small risk of a very great danger—but it exists, and now is the time to guard against it.

The word germ is used not only to designate independent organisms, which can grow outside the human body, but also particles of living matter which have formed a part of the living body itself, such as at present are believed to constitute the contagion of such diseases as small-pox, measles or scarlet fever, according to what is called the bioplast or graft theory. This use of the word germ is improper and confusing. This graft theory of disease is that a particle of animal matter growing, or capable of growth (bioplasm), may be transplanted and continue to grow; it will grow normally if it be normal, abnormally if abnormal, and so carry on in the new body the diseased process of which it has formed a part in the old. The results are supposed to be analogous to those observed in cases where from a stock below a graft, fruits and flowers of the kind borne by the scion have appeared, for instance, in the pear grafted on the mountain ash. This analogy did not escape Mr. Darwin, who says, "It is certain that where trees with variegated leaves are grafted or budded on a common stock, the latter sometimes produces buds having variegated leaves, but this may perhaps be looked at as a case of inoculated disease."

Because minute organisms are found in the blood and tissues in cases of disease, it does not by any means follow that they are the efficient causes of the disease. For example, last July, in Chicago, a boy was seized with tetanus as the result of a wound from the explosion of a toy pistol. Upon examination his blood was found to be swarming with sphæro bacteria. The blood of a horse affected with tetanus was then examined and found to contain similar organisms. Had they stopped there a very pretty theory of the germ origin of tetanus might have been constructed. But they proceeded to examine the blood of the mother and sister of the boy and found that it contained the same forms. Furthermore, after the boy had entirely recovered, his blood still was crowded with these bacteria. Whereupon it is suggested that this particular sphæro bacterium, at least, "should be recognized as an altogether pleasant and lovely schizomycete, dancing away its dizzy life in the vascular channels with a levity born of utter guilelessness. This is called the too-too theory. Nay more, it is claimed that this micrococcus should be regarded in the light of a benefactor. It carried the boy safely through an attack of tetanus and did not desert him when he was convalescent, it sustained his mother nursing with sore anxiety her only son, threw its protecting ægis over another child of the family, and enabled the mother at the same time to attend to the wants of her customers to whom she was in the habit of dispensing a superior quality of lager beer. How can we refuse assent to the proposition that this Chicago bacterium is a good thing to have in the family? In comparison with it, how worthless is the prescription of that obliging clergyman, whose sands of life have been running out—lo! these many years."

Some of the relations of meteorological conditions to disease, and especially to epidemics, depend, no doubt, upon the influence which these conditions exert either directly or indirectly upon the growth and development of the lower organisms. As an example of direct influence may be instanced the striking effects of cold upon yellow fever, a single sharp frosty night putting an abrupt end to an epidemic. As specimens of indirect influence we may consider the increase of typhus in cold weather due to over-crowding on the part of the poor for the sake of warmth, or the frequent outbreaks of typhoid fever after heavy falls of rain, due to the washing of the infectious particles of typhoid excreta into the sources of water supply. Temperature and light have a powerful influence on the growth of bacteria. Each peculiar organism requires a special temperature which often has very narrow limits. Koch states that the bacillus of tubercle will not propagate at temperatures below 86° F., and therefore it must gain access to the interior of a warm-blooded animal if it is to increase, unless, perhaps, in hot climates.

(*To be continued.*)

INULIN IN THE BRACTS OF THE ARTICHOKE.

The presence of a perceptible amount of inulin in the bracts of the artichoke (*Cynara Scolymus*) is recorded by Pistone and de Regibus in the *Journal of the Royal Turin Academy of Medicine*. The bracts were boiled in water until a dark-green sap could be expressed from them, which reduced with difficulty Fehling's solution. This was again boiled, and filtered off while hot. If slowly cooled, there was precipitated, after some time, a white flocculent substance, which, after repeated washing in boiling water and alcohol, proved to be nearly identical with Sachs's spherocrystals of inulin. It is not coloured by iodine, and turns the plane of rotation in the polariscope to the left, even in the presence of a dilute acid.

CHEMICAL COMPOSITION OF WOODY TISSUES.

In an inaugural dissertation before the University of Dorpat, N. Schuppe gives the following result of experiments as to the quantitative composition of different woody tissues.

Treatment with nitric acid and potassium chlorate confirms the accepted composition of cellulose, $C_6H_{10}O_5$, in the pine, poplar, mahogany, American and European nut, oak and alder. As regards the quantity of gum left after treatment with water, alcohol, and dilute soda lye, he finds none at all, or only a trace, in the wood of Coniferæ, 3·25 per cent. in the poplar, and 7·09 per cent. in the alder. For the wood of the European and American nuts he gets very nearly the composition of pure cellulose; for mahogany and oak $C_{14}H_{24}O_{11}$ $(=2C_6H_{10}O_5+C_2H_4O)$; for poplar and alder $C_8H_{14}O_6$ $(=C_6H_{10}O_5+C_2H_4O)$.

The woody fibre, after extraction of the gum, gave an average composition of C 45·4, H 5·9, O 48·7 per cent. The proportion of lignin to cellulose he found to be very nearly the same in different woods, and came to the conclusion that the strength or power of resistance of any particular kind of wood does not depend on the relative proportion of these substances, but on their varying molecular constitution.

For lignin Schuppe proposes the approximate formula $C_{19}H_{18}O_8$, nearly corresponding with that of catechin. Assuming the average proportion of lignin and cellulose in wood to be 17·6 per cent. of the former, and 40·7 per cent. of the latter, this gives an approximate formula for woody fibre of $5C_6H_{10}O_5+C_{19}H_{18}O_8$.

The Pharmaceutical Journal.

SATURDAY, JULY 21, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CHEMICAL INDUSTRIES.

THE recent meeting of the Society of Chemical Industry in London, the principal part of the proceedings at which we chronicled last week, furnished an ample justification for the attempt initiated two years ago to carry out the happy thought that there should be established in Great Britain a Society which should afford facilities for the interchange of information between persons interested in the application of chemical principles to manufacturing operations. As the Society has, in this short time, been joined by nearly fourteen hundred members, it may be said to have established a *raison d'être*, and it may be safely predicted that as long as the original object is kept in view, and the sections are preserved from the devices of interested *exploiteurs*, it will not lack ample support. Such stability is indeed very desirable, for the time appears to be approaching fast when, if England is to hold her own amongst other nations, one or more skilled workers in chemistry, or some allied science, will become an indispensable portion of the staff in every large manufactory. In this respect, in fact, this country has much lee-way to make up. Two years ago, at the first meeting of the Society, Professor ROSCOE forcibly pointed out that although almost all the raw material used in the manufacture of the coal-tar colours was produced in this country, England had a very small share in the profit derived from working it up into the finished article, nearly the whole of the coal-tar colours used by her calico printers, dyers and others being imported. And, unfortunately, the same statement could be made with equal truth at the present time. This unsatisfactory state of things is not, however, due to any inferiority in the workmen of this country, as was remarked by a speaker at the dinner last week; but to the fact that whilst our continental neighbours have been keen to perceive the advantage of applying scientific principles in the carrying on of great industries, and have wisely provided facilities for the training of men capable of such work, we have gone on from year to year content to practise the same "rule of thumb" that guided our forefathers. Another instance may be found in the rude shock to England's supremacy in the alkali manufacture which she has lately received at the hands of the makers by the ammonia process on the Continent.

It is important to observe that one fact which is becoming increasingly manifest in the struggle between the great manufacturers of the world is that the greatest amount of success will lie with those who do most towards making "waste" an obsolete term. Take for instance, the subject already referred to, the products of the destructive distillation of coal. The tarry bye-products which a few years ago were got rid of by the gas manufacturers at a great expense now form a source of income to the extent of several millions sterling annually, whilst the future of the LEBLANC soda industry seems almost dependent upon certain modifications of the coking ovens, which, by intercepting the nitrogenous constituents of coal, shall set up a new object to be attained as the principal end in the distillation, and remit what is now known as coal gas to the position of a bye-product, available in the neighbourhood of the works as a source of heat and light at almost a nominal price. Then the past year has seen the application of SCHAFFNER and HELBIG'S process, with promise of success, in the recovery of sulphur from "alkali waste," and those members of the Society of Chemical Industry who availed themselves of the invitation to visit the South Metropolitan Gas Works were privileged to inspect an experimental apparatus which may eventually afford help in the same direction, in which sulphuretted hydrogen removed from the "gas" as an impurity was being decomposed by passing over oxide of iron in the presence of a limited quantity of air, with the formation of water vapour and the deposit of pure sulphur.

Another beautiful illustration of the power of the chemist to transmute the baser elements into gold no doubt interested most of the members who visited the great sugar refinery of Messrs. DUNCAN and Co., where the process was courteously explained by its inventor, Mr. NEWLANDS. It is well known that the crystallization of cane sugar is greatly impeded by the presence of certain bodies derived like it from the cane or beet, which are sometimes capable of retaining in solution in the molasses as much as 50 per cent. of crystallizable sugar. Various plans have been tried to recover this sugar from the molasses, based upon the formation of an insoluble compound, and caustic strontia has been recently largely used for the purpose, it forming with the dissolved sugar an insoluble saccharate of strontium. Mr. NEWLANDS, however, attacks the difficulty from the other side, by removing the potash salts which are the principal impediments to the crystallization of the sugar. So well was this latter fact known that it has long been the custom to make an allowance to refiners for loss on this account in proportion to the amount of ash yielded by a sugar. About two-fifths of the total ash is potash. Mr. NEWLANDS, therefore, takes the liquor from which the cane sugar has been crystallized as far as possible by simple cencentration, estimates the amount of ash, and assuming that two-fifths of it is potash adds an equivalent of sulphate of alumina made from bauxite and another equivalent of sulphuric acid, and in this way obtains a splendid crystallization of potash alum, sometimes amounting to ten per cent. of the weight of the solution treated. The disturbing cause having thus been removed, the crystallization of the cane sugar can then be effected with tolerable completeness.

Adjoining Messrs. Duncan's sugar refinery, in the enormous guano and manure works of Messrs. Ohlendorff and Co., the chief portions of the operations are also based upon the application of the results of chemical investigations. The necessity that mineral and other phosphates before being used as manure should be converted into the soluble form is now well understood, although it proved for a time a stumbling-block in the way even of the great founder of agricultural chemistry. This conversion is effected on a large scale in these works by the ordinary treatment with sulphuric acid, Peruvian guano being the material most used. Some idea of the development that has taken place in this industry may be formed from the fact that in 1840 the total imports of guano into this country amounted to only twenty tons in the twelve months, whilst Messrs. Ohlendorff alone now claim to turn out upwards of a thousand tons of prepared guano and manufactured manures every week. At first the guano was sold as received, but the necessity for a preliminary treatment with sulphuric acid of guano damaged by wet before drying it in kilns suggested an extension of the process, and now the whole of the guano sent out by this firm is thus treated, the advantage claimed being that the ammonia is fixed as sulphate whilst the insoluble phosphates are at the same time rendered soluble. The sulphuric acid used for this purpose is manufactured on the premises, Spanish pyrites from the Tharsis Company's mines being burnt in the kilns and the desulphurized ore being returned to the Company in a better condition for the extraction of the copper than before it was burnt. In Messrs. Knight's works, too, which were also visited, the old chemical operation of soap-making is carried on side by side with the modern one of producing oleomargarine for the "butterine" manufacturers, whilst few of those who visited the new lager beer brewery of the Austro-Bavarian Company were unaware of the extent to which this industry has benefited by the investigations of the chemist. Moreover, in some of the manufactories visited, where other sciences than chemistry play the principal part, the visitors could not but be struck with the fact that—as in the preparation of vacuum capsules for incandescence illumination—manipulations which a few years ago would have been ranked among the impossibilities of physics were being carried on as an ordinary avocation, even by boys.

If a special moral needs to be pointed for the readers of this Journal, surely it is that at a time when the followers of every craft are striving to keep themselves abreast of scientific discovery, so as to be able to profit by it as promptly and as extensively as possible, the pharmacist must not be a laggard in the race. The man who allows himself to fall behind his customer in his acquaintance with the sciences which are supposed to be particularly associated with the practice of his calling can hardly expect to enjoy a large measure of public confidence.

At a recent meeting of the Council of the Liverpool Chemists' Association, the invitation of the Pharmacopœia Committee of the General Medical Council asking the co-operation of the Association in the revision of the British Pharmacopœia was considered, and a resolution was adopted to the effect that the Council could not see its way to act in the matter of the revision of the British Pharmacopœia, pending present legislation.

* * *

On Monday last, Mr. Mundella received two deputations on the subject of the Medical Acts Amendment Bill. The first was from the Medical Alliance Association, and urged that medical practitioners throughout the country should be directly represented upon the various divisional boards, that unregistered persons should not be allowed to practise, that there should be a common title for medical practitioners, and that power should be given to any person to prosecute offenders against the law. Mr. Mundella replied that the object of the Bill was not to impose pains and penalties, but to raise the status of the profession and improve medical education. He denied that it would operate to the detriment of the public by admitting incompetent practitioners, since the existing restrictions as to unregistered persons practising would be continued. The other deputation was from the Brussels Medical Graduates' Association in respect to the position of such persons under the Bill. It is now stated that the Government is prepared to meet the wishes of of the Scotch members who are opposed to the Bill, by giving an additional seat on the Medical Board to the College of Physicians at Edinburgh. The second reading was the sixteenth order of the day on Thursday.

* * *

The *Canadian Pharmaceutical Journal*, the official organ of the Ontario College of Pharmacy, in a sympathetic editorial, speaks in approving terms of the position taken by the Council of the Pharmaceutical Society of Great Britain in respect to the legal representation of pharmacists upon any Committee charged with the revision of the British Pharmacopœia. After describing the views set forth in the memorial to the Privy Council, it adds: "We do not exactly see how Canada and the Colonies come in under this arrangement; perhaps the parent Society thinks we are old enough to look after ourselves. But in any case we hope that the rights of pharmacists will be recognized, and the acknowledgment made that English druggists are at least as good as their neighbours."

* * *

A case involving an interesting point as to the responsibility of pharmacists has recently been before the Appeal Court of the State of New York. A man who had been recommended to take a wine-glassful of "black draught" appears to have taken an equal quantity of "black drops" instead, his death being the natural result. His relatives elected to bring an action for damages against the druggist at whose shop the black drops were purchased, but at the trial the assistant who served swore that he was asked for black drops by deceased and that he specially cautioned him that to take more than ten or twelve drops would be dangerous, though he admitted that he had failed to label the bottle "poison," in compliance with the law. The judge decided in favour of the druggist, on the ground that upon this testimony he was not liable. The Court of Appeal also held that, if the assistant's statement were true, the druggist would not be responsible after the caution had been given; neither would the assistant be civilly liable, though he might be liable to a criminal prosecution for not using a poison label. The Court, however, objected to the dismissal of the plaintiff's case by the judge before the probability as to the truth of the assistant's statement had been determined by a jury, and for this purpose ordered a new trial.

* * *

On Monday, the 2nd inst., a law respecting the tax upon proprietary medicines sold in the United States came into operation. According to the *Weekly Drug News*, the "proprietors" appear to be under the impression that the abolition of the tax had been effected in their interest rather than in that of the public, since there had been few indications of any intention to make a corresponding reduction in the prices. On the contrary, it is roundly asserted that since no alteration in prices was made when the tax was imposed, the public has no claim to profit by its abolition. As the tax amounted to about two million dollars annually, the manufacturers will have good reason to be satisfied if they succeed in maintaining their position.

* * *

According to the Scotch correspondent of the *Medical Press and Circular*, the case of poisoning at Partick, to which reference has already been made in these columns, is now alleged to have been due to a mistake made by a wholesale druggist. The explanation put forward is that tinct. actææ racemosæ was ordered by the prescriber, and that the dispenser used a tincture which had been supplied under this name by a wholesale house, but which was really tinct. aconiti.

* * *

The German Pharmaceutical Association will hold its Twelfth Annual General Meeting in Wiesbaden, commencing on Tuesday, the 4th of September and concluding on Friday, the 7th. In connection with the meeting there will be, as usual, an exhibition of objects of pharmaceutical interest, which will take place in the "Turnhalle" of the Gymnasium. On Wednesday evening there will be a banquet in the "Kurhaus," followed by an adjournment to the Gardens, which will be illuminated and where there will be a display of fireworks. On Friday the Association will make an excursion to the Niederwald.

* * *

The Annual Meeting of the School of Pharmacy Students' Association will be held on Thursday, July 26, when the chair will be taken at 8 p.m. by the President, Professor Attfield, F.R.S., and the annual report of the Executive Committee will be read.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

July, 1883.

Present on each day—Messrs. Ainslie, Baildon, Clark, Gibson, Gilmour, Kinninmont, Nesbit and Stephenson.

Professor Maclagan attended on the 12th on behalf of the Privy Council.

MAJOR EXAMINATION.

11*th.*—*Two* candidates were examined. *One* failed. The undermentioned passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Dott, David Brown .... Edinburgh.

MINOR EXAMINATION.

11*th.*—*Nine* candidates were examined. *Four* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Arthur, John ....Chesterfield.
Bowman, Edmund ....Leith.
Clegg, George ....Accrington.
Cochrane, James ....Glenclelland.
Collins, Henry ....Ashton-under-Lyne.

12*th.*—*Eleven* candidates were examined. *Five* failed. The undermentioned *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Coull, George ....Edinburgh.
Duncan, William ....Montrose.
Findlater, William Gammie ...Aberdeen.
Harrison, John.....................Lincoln.
Hartley, Walter Edward ......London.
Horsfield, Frank ....Holbeck.

13*th.*—*Ten* candidates were examined. *Six* failed. The undermentioned *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Lipp, George.......................Elgin.
MacRitchie, David, jun...........Inverness.
Robertson, Charles ....Edinburgh.
Wright, John Leonard ....Liverpool.

MODIFIED EXAMINATION.

13*th.*—*One* candidate was examined, and was declared qualified to be registered as a Chemist and Druggist:—

Bottomley, Lawrence Whinray..Sheffield.

SOCIETY OF CHEMICAL INDUSTRY.

Stassfurt Salts and their Mode of Treatment.*

BY C. NAPIER HAKE.

In bringing before you this evening some details respecting Stassfurt salts and their mode of treatment, I feel that it is a subject which cannot fail to be of interest to the English manufacturer, if only for the reason that one-third of the total produce of the Stassfurt mines finds its way into English markets.

Stassfurt is a small town of some 12,000 inhabitants, about twenty-five miles south-west of the city and fortress of Magdeburg, in Prussia. It lies in a plain, and the river Bode, which takes its rise in the Harz mountains, flows through it. The history of the salt industry in Stassfurt is a very old one, and dates back as far as the year 806. Previous to the year 1839 the salt was produced from brine pumped from wells sunk about 200ft. into the rock. The brine, in the course of time, became so weak, as regards the common salt it contained, that it

* Read at a meeting of the London Section of the Society, April 2.

was impossible to carry on the manufacture from this source without loss. In 1839 the Prussian Government, who were the owners of these saline springs, commenced boring with the object of discovering the whereabouts of the bed of rocksalt from which the brine had been obtained, and in the year 1843 the top of the rocksalt was reached at a depth of 256 metres. The boring was continued through another 325 metres into the rocksalt without reaching the bottom of the layer. At this total depth of 581 metres the boring was suspended. On analysing the brine obtained from the bore-hole, it was found to consist, in 100 parts by weight, of—

Sulphate of calcium	4·01
Chloride of potassium	2·24
Chloride of magnesium	19·43
Chloride of sodium	5·61

A result not only unexpected but disappointing, since the presence of chloride of magnesium in such quantities dispelled for the time all hopes of striking on the pure rocksalt. The Government, however, guided by the opinions expressed by Dr. Karsten and Professor Marchand, namely, that the presence of chloride of magnesium in such quantities was probably due to a deposit lying above the rocksalt, determined to further investigate the matter, and in the year 1852 the first shaft was commenced, which after five years had penetrated, at a depth of 330 metres, into a bed of rocksalt, passing on its way, at a depth of 256 metres, a bed of potash and magnesia salts of a thickness of 25 metres.

The lowest deposit of all consists of rocksalt. The bore-hole was driven 381 metres into it without reaching the bottom of the layer. Its depth is therefore unknown. Occurring in the rocksalt deposit are thin layers of sulphate of calcium 7 millimetres thick, and almost equidistant. At the top of the rocksalt are thin layers of the trisulphate of potash, magnesia, and lime as the mineral polyhallite. The deposit lying immediately on the bed of rocksalt consists chiefly of sulphate of magnesia as the mineral kieserite. Still further towards the surface the deposit consists of the double chloride of potassium and magnesium, known as the mineral carnallite, mixed with sulphate of magnesia and rocksalt. The deposit on the rise of the strata, consists of the double sulphate of potash and magnesia combined with one equivalent of chloride of magnesium, and intermingled with common salt to the extent of 40 per cent. This double sulphate is known as the mineral kainite, and is a secondary formation, resulting from the action of a limited quantity of water on a mixture of sulphate of magnesia and the double chloride of potassium and magnesium, as contained in the uppermost deposit previously spoken of.

The upper bed of the rocksalt, resting on a thick bank of anhydrite, is also a later formation. Almost imperceptible layers of polyhallite are present in this deposit and at greater intervals than in the lower and older deposit. It has, therefore, probably originated from the action of water on the older deposit. This upper bed of rocksalt varies in thickness from 40 to 90 metres, and its extent is comparatively limited. It is worked in preference to the older deposit, where both exist in the same mine, it being of much purer quality, averaging about 98 per cent. in the mines of the New Stassfurt Mining Company and in the Royal Prussian mines.

Sixteen different minerals have as yet been discovered in the Stassfurt deposits. They may be divided into primary and secondary formations. Those of primary formation are rocksalt, anhydrite, polyhallite (K_2SO_4, $MgSO_4$, $2CaSO_4$, $2H_2O$), kieserite ($MgSO_4$, H_2O), carnallite (KCl, $MgCl_2 6H_2O$), boracite ($2(Mg_3B_8O_{15})$,$MgCl_2$), and douglasite (2KCl, $FeCl_2$,$2H_2O$). Those of secondary formation, resulting from the decomposition of the primary minerals, are nine in number, namely:—kainite (K_2SO_4, $MgSO_4$, $MgCl_2 6H_2O$), sylvin (KCl), tachydrite ($CaCl_2$, $2MgCl_2+12H_2O$), bischofite ($MgCl_2$, $6H_2O$), krugite (K_2SO_4, $MgSO_4$, $4CaSO_4$, $2H_2O$), reichardtite ($MgSO_4$, $7H_2O$), glauberite ($CaSO_4$, Na_2SO_4), schönite (K_2SO_4, $MgSO_4$, $6H_2O$), and astrakainite ($MgSO_4$, $4H_2O$). Only four of these minerals have any commercial value, namely:—carnallite, kainite, kieserite and rocksalt. The yield of boracite, which is found in nests in the carnallite region of the mine, is too insignificant to be classed among those just mentioned.

The mine may be divided chemically into four regions, (1) the rocksalt, (2) the kieserite, (3) carnallite, (4) the kainite region.

The rocksalt region has almost the same composition throughout. Its character is crystalline, though in this region well-defined crystals are never met with. In other parts of the mine, especially in the carnallite region, it is found crystallized in three distinct forms—the cube, the four-faced cube, and the octahedron, coloured different shades of red and blue. Specimens have also been found of varied structure, laminated, granular and fibrous.

The rocksalt is ground more or less fine according to requirement. Before passing through the mill it is sorted by hand labour, the purest being utilized as table salt, large quantities of which are exported even to India. The finest quality is sold at about 10*s*. per ton, the second quality, containing about 98 per cent. of chloride of sodium realizing about 5*s*. per ton. The accompanying table shows the output of rocksalt and other minerals, in tons, between the years 1861 and 1881:—

	Rocksalt.	Carnallite and Kieserite.	Kainite.	Various minerals.
1861–1865	44,494	29,603	—	—
1866–1870	58,937	118,099	11,689	—
1871–1875	64,233	433,859	18,039	—
1876–1880	96,856	643,363	55,773	—
*1880	118,105	528,211	137,795	4,100
*1881	149,222	744,722	155,301	5,300

The deposit lying on the top of the rock constitutes the so-called kieserite region. The thickness of this deposit is about 56 metres, and its average composition as follows:—

	Per cent.
Kieserite	17
Rocksalt	66
Carnallite	13
Tachydrite	3
Anhydrite	2
	100

In the pure state kieserite is amorphous and translucent, possessing a specific gravity of 2·517. It contains 87·1 per cent. sulphate of magnesia and 12·9 per cent. water, corresponding to the formula $MgSO_4$,H_2O. Exposed to the air it becomes opaque from the absorption of moisture, and is converted into Epsom salts; 100 parts of water dissolve 40·9 parts of this mineral at 18° C. The solution, however, takes place very slowly at this temperature.

This deposit has not been worked to any great extent. Its composition is interesting as showing the gradual decrease of the proportion of common salt and the commencement of the separation of the more soluble salts.

Each of the two divisions of the mine just described contains only one mineral of importance. The third division, called the carnallite region, contains a variety of minerals, and to this deposit Stassfurt owes its world-wide fame. The average thickness of this

* These quantities were supplied by four mines, namely, Royal Mine, Stassfurt, the Leopoldshall Mine, the New Stassfurt Mine, and the Douglashall Mine, belonging to the Consolidated Alkali Company.

deposit is about 25 metres, and its composition is as follows:—

	Per cent.
Carnallite	60
Kieserite	16
Rocksalt	20
Tachydrite	4

besides small quantities of magnesium bromide. These minerals are deposited in the order given above, in successive layers, varying in thickness from $\frac{1}{100}$ to 1 metre, the different colours of these minerals giving the deposit a remarkable appearance.

The predominating mineral in this region is carnallite, a double chloride of potassium and magnesium, containing 26·76 per cent. chloride of potassium, 34·50 per cent. chloride of magnesium, and 38·74 per cent. water, corresponding to the formula $KCl,MgCl_2,6H_2O$. In the pure state it is colourless and transparent, and possesses a specific gravity of 1·618. It is very hygroscopic, and is easily soluble in water, 100 parts of which dissolve 64·5 parts of the mineral. It may be artificially formed from a solution of chloride of potassium, containing not less that 26 per cent. of chloride of magnesium. The secondary formation, as before mentioned, consists principally of the mineral kainite. This deposit, though limited as compared to the other salt deposits, is yet of vast extent. The average composition of this deposit is:—

	Per cent.
Sulphate of potash	23
Sulphate of magnesia	15·6
Chloride of magnesium	13·0
Chloride of sodium	34·8
Water	13·6
	100·0

In the pure state it is colourless and almost transparent, and possesses a specific gravity of 2·13; 100 parts of water dissolve 79·5 parts of it. Cold water does not decompose it, but from its saturated hot solution the double sulphate of potash and magnesia separates, and chloride of magnesium remains in solution.

This brief explanation of the various strata will, I think, suffice to give you a clear idea of the character of the mines from which the raw materials are drawn, and before describing the chemical treatment of the deposit, I should like to give you, in as few words as possible, the generally-accepted theory of their formation.

The entire deposit is supposed to have resulted from the evaporation of an inland sea in communication with the ocean. The water of this inland sea must have become more and more concentrated as time went on, owing to evaporation, until the point of saturation was reached, when the common salt would begin to separate. This would naturally take place during the hot summer months, while during the winter months, when the temperature was considerably lower, the calcium sulphate deposited from the fresh inflowing water, each gypsum zone marking a new period of precipitation. These zones, like the circular rings in trees, afford us a basis for speculation regarding the period of time during which the deposit was in course of formation. Thus, supposing the rocksalt deposit to be 600 metres thick, 6600 years would have elapsed during the process. Reverting once more to the question of the precipitation of these salts, let us assume that the connection between this inland sea and the ocean had been cut off for some time. The mother liquor, though still containing common salt in large proportions, would also contain all the more soluble potash and magnesia salts which had been accumulating during the previous period. As evaporation went on, the common salt and calcium sulphate would have been still alternately deposited until the point of saturation was reached, when the potash would be thrown down in the form of the trisulphate of potash, magnesia and lime, and in the place of the calcium sulphate. At a higher degree of concentration, and consequently at a later period, sulphate of magnesium was precipitated, accompanied by a small proportion of carnallite, and finally, the most soluble salt of all, the double chloride of potassium and magnesium, separated out with sulphate of magnesium in the proportion of 60 per cent. carnallite to 16 per cent. kieserite. The precipitation of common salt continued to the end, but its proportion to the other salts decreased towards the surface. The deposit, which originally had the shape of a basin, was lifted in the centre by volcanic action, the fault striking S.W. The deposit is protected from the solvent action of water, first, by a layer of clay, and further, by a thick layer of anhydrite, the stratum above consisting to a large extent of the "Bunter" sandstone.

There are eleven mines sunk along the strike of the fault. At Aschersleben the deposit lies almost horizontal. In Stassfurt the dip of the deposit is 40° in the Prussian mine and 60° in the New Stassfurt mine, and at the other end of the fault the deposit is almost vertical. Only one shaft has been sunk on the east border of the fault, the other ten being situated on the west side. The distance from the Aschersleben shaft to the Douglashall shaft is about ten miles.

These potash deposits, instead of being regarded as a source of profit, were looked upon for some time as an incumbrance. When they had to be removed, in order to more economically work the rocksalt, they were carted on to the banks of the river to be washed away during the period of the floods. The first attempt to utilize these deposits as a raw material in Stassfurt was made by Dr. Frank, who established a factory in the year 1860. He was shortly followed by Dr. Gruneberg and Messrs. Leisler and Townsend, and in the year 1863, 13,500 tons of raw material were consumed by eleven factories. At the present time the manufacture of chloride of potassium, etc., is carried on by the following firms:—

Ascania Company Limited, Leopoldshall; Beit and Philippi, in Stassfurt; Concordia Company Limited, Leopoldshall; Harburg-Stassfurt Company Limited, in Stassfurt; N. F. Loefass, in Stassfurt; The Mineral Salts Production and Moorlands Reclamation Company, in Aschersleben;* Consolidated Alkali Company Limited, in Wester Egeln;* Lindeman and Company, in Stassfurt; Maigatter, Green and Company, in Leopoldshall; Müller and Allihn, in Leopoldshall; F. Müller, in Leopoldshall; F. R. Müller and Company, in Schönebeck; C. Nette Faulwasser and Company, in Leopoldshall; Schachnow and Wolff, in Leopoldshall; Stassfurt Chemical Company Limited, in Stassfurt; Stein and Keitz, in Leopoldshall; United Chemical Company Limited, in Leopoldshall; Vorster and Gruneberg, in Leopoldshall; Wüstenhagen and Company, in Hecklingen.

Parliamentary and Law Proceedings.

Death from an Overdose of Laudanum.

An inquest was held at Exeter, on Saturday, July 7, touching the death of Mary Ann Harriett Southcott, a widow, who had died from the effects of poison on Friday.

Deceased was found by her sister on the bed, apparently asleep. Her sister attempted to arouse her, but was unsuccessful. Two small bottles, both empty, and labelled "laudanum," being noticed in the room, a surgeon was sent for, and promptly administered two emetics, which were both effective. The surgeon left,

* These two companies are owners of mines and work their own raw material.

giving instructions that deceased was to be walked about the room, but after this had been continued for some time she became tired and sat on the edge of the bed, and while in that position she suddenly expired. Deceased had purchased the poison at Mr. Tighe's, chemist, High Street, stating that she knew its nature, and was in the habit of taking it. The deceased's husband had also been in the habit of taking laudanum.

The medical evidence went to show that death was caused by cardiac syncope, resulting from the use of laudanum acting on a circulation enfeebled by age, and a verdict of "Death from misadventure" was returned. —*Western Morning News.*

Poisoning by Sulphuric Acid.

A case of poisoning is reported from Doncaster, in which a child, having been left alone for a time, opened a cupboard and drank some sulphuric acid, which had been kept for disinfecting the stable during the time the horses had the "pink eye." The child was removed to the infirmary, but died soon afterwards.

The Case of Poisoning by Essential Oil of Almonds.

At the Maidstone Assizes on Wednesday, before Mr. Justice Day, the Rev. John Henry Timmins, vicar of West Malling, was placed at the bar to take his trial on a charge of manslaughter in feloniously killing and slaying one Sarah Anne Wright.

Mr. Talfourd Salter, Q.C., and Mr. Eyre Lloyd, instructed on behalf of the Treasury, appeared to conduct the prosecution; and Mr. Edward Clarke, Q.C., and Mr. D. Kingsford were for the defence.

The accused, who has been for about forty years vicar of West Malling, is apparently about seventy years of age, and, as stated by the counsel for the prosecution, had been very much respected, especially for his attention and kindness to the poor. It was also stated that he had in early life attended lectures in St. Thomas's Hospital and so acquired some knowledge of medicines and drugs. The deceased was a young girl about sixteen years of age, the daughter of a labourer, one of his parishioners, whose family he was in the habit of visiting. The girl herself seemed from some cause to be ailing, and for several days the accused had been to see her and had given her medicine. On December 14, he went to see her, and asked her how she was, and she said she was much better. He asked for a glass, took a bottle out of his pocket, and taking something out of the bottle, put it into the glass and asked for some water, but there was none. He gave her what was in the glass. She at first refused to take it, but he said it would do her good, and she took it. She at once got up from the sofa on which she was lying and screamed and said, "Oh, Mr. Timmins, Mr. Timmins!" He asked for water, and meanwhile got her to sit down on a chair and put her head on his shoulder, and said she would get better. She drank some of the water, and then she laid on the sofa for some time. He took the glass and offered it to the girl's mother, who refused it, and he then offered to drink from it himself. After he had gone, she rose up, staggered, and foamed at the mouth, and soon afterwards she vomited. After twenty minutes or half an hour the nurse went for the defendant, who brought some brandy and tried to give the girl some mixed with water, but it could not be got into her mouth. The doctor was then sent for at the vicar's desire, but before he came—in less than two hours from the time of the administration of the drug—the girl died. It turned out that what had been administered was, in fact, the bitter oil of almonds, which had been obtained by the vicar from the chemist some time before, and which it was said was the same as "essential oil" of almonds, and contained a large percentage of prussic acid.

Mr. Salter, in opening the case for the prosecution, said the vicar had administered the "bitter" or "essential" oil of almonds, which he surely must have known contained a large percentage of prussic acid. Indeed, it appeared from the previous correspondence with the chemist that he must have known it. How he came to administer the poison was inexplicable. No one suggested any but a good motive for it. But if he had rashly experimented and out of sheer rashness had given the girl the drug, the jury must convict him of manslaughter.

It appeared that a son of the vicar had for some weeks had a nettle-rash, and he had got from the chemist an ounce of "bitter" or "essential" oil of almonds, which he administered externally. It was obtained by a written order in his handwriting, though not signed by him. The chemist sent a note in these terms:—"Rev. Sir,—I have received the enclosed order for an ounce of essential oil of almonds. It being very poisonous, be good enough to inform me if that is the article you require." To which the vicar sent a written reply, "I require the bitter almond oil for external application, and I will see to its proper use." The chemist stated that the phial had on it a label, "Essential oil of almonds," and also a printed label, "Poison." "Bitter" and "essential" oil of almonds were in reality identical, and contained a proportion of prussic acid. Prussic acid, he said, was volatile, and as it had been in his stock eighteen months, the percentage probably was reduced. He did not know of its been used as a medicine taken internally. In cross-examination, he said there was an oil "expressed" from almonds and an oil expressed from sweet almonds which were harmless. Before this case he had never known the essential oil of almonds used even externally, and poison might be absorbed. It appeared from the *post-mortem* examination and analysis that death had been caused by prussic acid contained in the essential oil of almonds.

The medical man who was sent for, and took part in the *post-mortem* examination, stated that the death was caused by essential oil of almonds. Prisoner told him on the occasion that he had "administered a teaspoonful, which was innocuous," adding that he had tried to give her brandy, but she had died a quarter of an hour before. He offered to send him the bottle which had contained the oil, but he had never done so. In cross-examination, he said a death in an hour and three-quarters from prussic acid was unusual, but there was a case of death in three hours. Death, under certain circumstances, might be delayed. The innocuous oil of almonds was yellow, and the "essential" oil became so when kept for some time.

Professor Heaton, lecturer on chemistry at Charing Cross Hospital, stated that the bitter and "essential" oil of almonds were the same, and contained a variable proportion of prussic acid. In what remained in the chemist's bottle there were 3·5 per cent. of prussic acid, which would give 2 grains in a teaspoonful—sufficient to cause death. He explained the difference between the "expressed" oil of almonds, which was innocuous, and the essential oil, which was poisonous.

This was the case for the prosecution, upon which

Mr. T. Salter, addressing the jury, said the question was whether the prisoner could have reasonably mistaken the nature of the almond oil he was giving to the girl. Even if he supposed what he administered was not the poison, he ought to have taken care to be certain of that, besides which there was the previous correspondence with the chemist, and the fact that the bottle was labelled "Poison."

Mr. Clarke addressed the jury on behalf of the prisoner, characterizing the case as one of the most painful he had ever known. After a career of forty years spent in the discharge of his sacred duties, and the exercise of charity, the prisoner found himself, by one unhappy mistake, placed in this painful position. The prisoner had written for "oil of bitter almonds" for external application, though the chemist had sent essential oil of almonds, which, it appeared, was not used for external application, and the prisoner had supposed the innocuous oil of almonds was sent. The chemist said he had put the poison label on the bottle, but that was only his recollection. The mother had not observed the poison label on the bottle. Besides, even if the label had been on the bottle, the prisoner might have supposed it was not poisonous, though so labelled, and his subsequent conduct showed no suspicion in his mind of poison. He asked the jury, therefore, upon this evidence that his client might be liberated.

Witnesses of high position were called, who gave the prisoner the best character for charity, kindness, and benevolence.

Mr Justice Day, in summing up the case to the jury, said this was a charge of homicide by negligence, and it was clear that the prisoner had caused the death of the deceased by the administration of a poison; the question for them was whether he had done so under circumstances which made him criminally liable. Unless gross negligence was established against the accused, it would be their duty to acquit him. None of the facts of the case were in dispute; it was for them to draw the inferences they deemed just, and the first question was—What did the prisoner send for? That was shown by the written correspondence between the prisoner and the chemist, from which it appeared that he knew he was to receive poison, and the chemist put upon the bottle the label "Essential oil of almonds;" it was also marked "Poison." The question was whether the administration of poison under such circumstances was or was not criminal negligence. A person who took upon himself to administer such a drug was bound to be careful; and in this case it was clear that there had been a want of care.

The Jury retired to consider their verdict at a quarter to four, taking the bottles with them, being cautioned as to which of them contained the poisonous preparation. In five minutes they returned into court with a verdict of "Not Guilty," which was received with some applause, and the prisoner was at once discharged.—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 16th of June, Mr. George Delves, Pharmaceutical Chemist, High Street, Exeter. Aged 46 years. Mr. Delves had been a Member of the Pharmaceutical Society since 1872.

On the 7th of July, Mr. George Henry Coates, Chemist and Druggist, Church Street, Barlow, Derbyshire. Aged 57 years. Mr. Coates had been a Member of the Pharmaceutical Society since 1871.

Correspondence.

Test for Arsenic in Domestic Fabrics.

Sir,—I observe in the "Report of a Committee appointed by the National Health Society," for the purpose of recommending a test for the certain detection of arsenic in domestic fabrics, the following remarks on Reinsch's popular test:—"We were at first of opinion that Reinsch's process, carefully conducted so as to insure uniformity of results, might be employed; but several wall papers and many textile fabrics having been found which gave no arsenical reaction with Reinsch's test, however carefully conducted, but which, nevertheless, were subsequently proved to contain notable quantities of arsenic, this method was proved not to be an absolutely reliable test." On referring to the detailed instructions for performing the test in question, it will be seen that the possibility of the arsenic existing in the higher stage of oxidation has not been provided for. Hence, probably, the occasional failure. Reinsch's process is from its great ease and quickness of execution so general a favourite that it is desirable to point out that in certain cases it is, unless proper precautions be taken, liable to deceive. I unfortunately have not access to Reinsch's original paper, so cannot say whether he was or was not aware of the fact that the mirror is not easily, if at all, produced on the copper foil in the case of the arsenic being present as arsenic acid; but I believe the fact is known and taught in the text books, though not in all of them. I would suggest then that after boiling for half an hour (or half that time) the acid liquid containing the copper foil and the colouring matters without the appearance of the mirror, a few crystals of sodic sulphite be thrown in at intervals of a few minutes and the boiling continued. If arsenic acid be present, its reduction to arsenious acid will take place immediately, and its further reduction to the metallic state forming the arsenical mirror will follow promptly. By thus dividing the boiling into stages the degrees of oxidation may be discriminated and ofttimes the offending colour "spotted." The nascent hydrogen evolved in Marsh's process effects the desire reduction, whatever the degree of oxidation of the arsenic present.

I will venture to add a recommendation as to the treatment of the mirrored copper foil, which I have practised for some years. I think I once mentioned it at a meeting of the British Pharmaceutical Conference, but am not sure it ever appeared in print. It is as follows:—The foil having been carefully washed and dried is doubled up and bent by means of pliers so as to fit pretty accurately the bottom of a small test tube. Into this tube is lowered a second and smaller test tube containing a little cold water. This tube should be just able to slide into the larger tube, and should be held by the finger close to the copper foil lying at the bottom of it. Heat from a very minute gas jet is now cautiously applied to the foil, and after a few seconds a white efflorescence will make its appearance on the cold end surface of the inner tube. The covering quality of arsenious acid is so great that an extremely minute quantity is readily observable. The inner tube being withdrawn, it can be subjected to optical and other tests with great facility. It is, I find, comparatively easy to obtain from half a minim of Fowler's solution all the important arsenic reactions, and doubtless if the mirror and white sublimate only be demanded, the process is capable of further refinement, though I doubt much its capability of satisfactorily indicating the ·001 grm. as required by the Reporters.

Thos. B. Groves.

"Easton's Syrup."

In reply to your correspondent "John," the above syrup, made with sulphate instead of phosphate of quinine, turns out quite satisfactory. By age it gradually acquires a little discoloration, just as most of these syrups do. I have not noted any "milky" appearance when made with Howard's quinine, but if some of the continental brands be used, "guaranteed to stand Pharmacopœia tests," then a syrup becoming milky in the course of six or eight hours is usually the result. This I have attributed—without special examination—to the cinchonidine sulphate nearly always present, in considerable proportions, in foreign quinine sulphate.

8, *The Strand, Torquay.* Edward Smith.

Methylated Iodine Preparations.

Sir,—It is a pity that Mr. W. H. Darling does not give any data for his authoritative statement that the pungency of methylated iodine preparations is due to acetone alone. From experiments which I have made I have found that this is not the case. It should not be forgotten that the pungency referred to in my note is accompanied by a distinctly alliaceous odour, such as characterizes bodies of the allyl series.

I need not say that the existence of allyl alcohol in wood spirit is now an accepted fact, and can be very readily demonstrated.

The whole aspect of the subject, however, I hope to discuss when I have completed the investigation on which I am at present engaged.

Edinburgh. PETER MACEWAN.

A QUERY REQUIRING AN ANSWER.

Sir,—When the present British Pharmacopœia was published I was much struck at the weakness displayed, especially in some of the galenical preparations. Extractum cinchonæ liquidum was one of these. One or two medical men, accustomed to use Battley's bark, asked me if it was a reliable substitute for that preparation. I replied most certainly not, and moreover, at once proved the fact to their entire satisfaction.

There is no disguising the fact that many of our Pharmacopœia preparations are "ghostly enemies" of so-called patent or proprietary medicines, with lawful names, under the plea that we like to know what we are giving; it is so unscientific to use a quack remedy.

Considering the profound knowledge possessed by the faculty of the use and action of such et ceteras as the spleen, thyroid and thymus gland and the suprarenal capsules, the force of the remark is of course evident, at least to persons who cannot perceive incongruities.

In the early years of this century in the city of London there lived, one whom I am pleased to call the Bellini of pharmacy, Richard Battley. Some years ago, when our able pharmacologist, Professor Redwood, was discoursing on the patient long suffering labours of the alchemists, men who watched their stills with astounding patience, while the gentle heat produced by fermentation carried over some hoped-for treasure into the receiver, I mentally drew a picture of that last of the race, Richard Battley.

Accident and experience have perhaps taught me more of the great triumphs of that honest worker than has fallen to the lot of some of my pharmaceutical friends. Mr. Battley, I believe, took the bark and literally pegged away at it with water; he steeped it, he boiled it again and again till there was nothing left but woody fibre and cellulose; he then strained and concentrated his liquor so that by the addition of the necessary spirit to preserve it each pound should contain the kinates of one pound of the finest bark; it was then set aside for several weeks to allow the kinate of lime and other earthy salts to crystallize out; the liquor was then poured off the crop of clear crystals, the proportions re-established, and the extractum cinchonæ liquidum, or as he called it, liquor cinchonæ, was ready for use.

My data for the foregoing hypothesis are these. Mr. Battley says on the label the decoction can be made from it, therefore all that boiling can do has been done. During the Crimean war the unusual demand prevented Messrs. Battley and Watts from allowing the kinate of lime to crystallize out before sending it to their customers; I was a young apprentice in those days and collected some very nice crops of crystals.

The preparation is, as far as my experience goes, unique. Like his liquor opii sedativus, there is nothing equal to it in its physiological action. I regret to believe the real barrier to their more extended use has been their price. I doubt if it is possible to lower it to any great extent, and until we can make preparations of bark and opium equal to them we are morally bound to use them, regardless of cost. Assertion is not fitting for men of science: we must prove our results by specific gravity, by estimation of the alkaloids, by chemical tests, and above all by the microscopical slide.

Mr. Wells says we are really without an extract representing the constituents of bark. For the sake of raising the question, I deny it. I say that Mr. Battley's preparation does fully and completely represent the constituents of this valuable remedy.

When the question of cost is relegated to the public and our good Bloomsbury boys have raised the profession of pharmacy to the level of a fine art, Richard Battley will occupy one of the foremost places on the scroll of pharmaceutical fame.

It is beside the question to say it is a proprietary medicine; that it is "liquor cinchonæ cordifolia, Battley," and should be ordered as such if required; that it is not B.P. May I conclude by answering these quirks, they are nothing more, by daring to alter our great poet's lines?—

"These medicines are kinder to the patients far
Than the two daughters culled from lawful sheets."

GEORGE MEE.

POISONING BY TARTAR EMETIC.

Sir,—In your issue of the 14th inst., you notice a paragraph in the *British Medical Journal* stating a woman had taken at least 7½ grs. of tartar emetic and recovered.

I remember, fifty years ago, a nurse giving a consumptive patient in lieu of a morning draught, a liniment containing ℈j tartar emetic and ℥ij liniment of soap.

On drinking copiously of warm water he recovered with no material ill effects.

56, *Dean Street,* WM. PROCTER, M.P.S.
Newcastle-on-Tyne.

N. D.—The white flocculent precipitate generally left when chloride of zinc is dissolved in water is oxychloride. Hydrochloric acid should not be added to dissolve it; neither does the bottle require a "shake" label.

"*Junior Assistant.*"—Dissolve the potassium iodide and potassium bromide in two thirds of the water, and add the spirit of chloroform to the solution. Rub the quinine with a little mucilage, and having added the remainder of the water, mix this with the solution. Decomposition will gradually take place with formation of hydriodate of quinine.

B. H. E.—Use glycerine of tragacanth as an excipient, after the addition of a very few drops of acid. phosph. dil.

J. S. Shortt.—The excipient ordered is unsuitable for potassium permanganate. See the correspondence on the subject in the last volume of the *Pharmaceutical Journal*, pp. 580, 600, 620, 640, 660.

J. Fingland.—(14) *Carex elongata.* (15) *C. lævigata.* (16) *C. pulicaris.* (17) *C. sylvatica.*

H. Bell.—Dr. Coghill's formula for an antiseptic solution for inhalation (*Lancet*, October 20, 1877) is, "Spirit of creasote, two drachms; carbolic acid, glycerine, of each half an ounce; distilled water to two ounces. Mix. Ten or twelve drops for inhalation." The formulæ for the vapores (1) acidi carbolici, (2) creasoti, and (3) iodi, of the Throat Hospital Pharmacopœia, are respectively: (1) Carbolic acid, 21 drachms; water, 3 fluid drachms. Dissolve. (2) Creasote ½ fl. oz.; light carbonate of magnesia, 90 grs.; water to 3 fluid ounces. Mix. (3) Pour ten drops of tincture of iodine into the apparatus for dry inhalation and inhale the vapour.

A. W. Turpin.—"Cinnabar of antimony" is a synonym for vermilion.

G. Thurlby.—*Hottonia palustris.*

W. H. and S.—The process is described in the British Pharmacopœia (Additions) under the heading "Bismuthi Oxidum."

D. Stewart.—We cannot say with certainty, but we think not.

Mr. Lennox Browne.—We are obliged to you for your letter, which, however, we do not think it advisable to publish. We hope, however, that you will do what you can to enlighten medical opinion on the subject.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Bell, Jobst, Carr, Waldheim, Williams, Alpha, Querens.

"THE MONTH."

The time for recreation and relaxation from work is now fast approaching, and those who have any love left for botanical pursuits will be hastening, vasculum in hand, to visit localities for rare plants, or to explore districts hitherto not thoroughly explored. That there are many such still left is evident from the many plants new to Britain which have recently been discovered. During the last month, the rare orchid, *Sturmia Loeselii*, supposed to be nearly extinct, has been rediscovered in two widely distant parts of Norfolk, one of the localities being a hitherto unrecorded one. *Naias major*, a plant entirely new to the flora of this country, has also been detected, and *Chara stelligera* has been found with antheridia in a new locality in the same county.

At the Botanical Gardens at Regent's Park the squill, *Urginea scilla*, is now in full blossom, and both at these gardens and at Kew the number of medicinal plants is larger perhaps than at any other time of the year. It seems unfortunate that botanical studies in the schools should be completed just when so much floral beauty is in its prime.

On the buckthorn plant may now be found, in damp localities, a pretty yellow fungus distorting the petioles or forming conspicuous spots on the leaves. It belongs to the heterœcismal fungi and is a stage of growth of *Puccinia coronata*. A good deal of discussion has lately been carried on in the columns of the *Gardeners' Chronicle*, with regard to this group of plants, and Mr. C. B. Plowright, of Lynn, failing to convince his opponents by argument, advises them to put the matter to the proof and to place a leaf of coltsfoot affected with the *Æcidium Tussilaginis* on well watered plants of *Poa annua*, which he states in ten or fifteen days will be affected with the *Uredo* and soon after with the *Puccinia poarum* (*Gardeners' Chronicle*, June 30, p. 824).

At the meeting of the Royal Horticultural Society, on June 20, Mr. Loder exhibited a specimen of *Digitalis* in which the terminal flower had assumed a campanulate form by two or three blossoms having combined. Mr. Henslow exhibited a specimen of *Ranunculus aquatilis*, grown on damp soil, which differed from the plant grown in water in the filiform segments having abundance of stomata, which are absent when the plant is submerged (*Garden*, June 30, p. 599).

In the Year-book of the Royal Botanical Gardens at Berlin, Professor Eichler has lately described a singular Brazilian tree, *Anona rhizantha*, which derives its specific name from the fact that the trunk sends out root-like, slender branches devoid of leaves, which bear flowers at their ends, the flowers being thrust into the ground as the branches lengthen, just as in the case of the peduncles of *Arachis hypogœa* (*Gard. Chron.*, June 30, p. 816).

Mr. T. Meehan has demonstrated that the supposition that the expansion of the sap by freezing causes trees to burst is incorrect as regards live wood, and in trees varying from 1 to 3 feet in diameter, and that, on the contrary, there is a contraction which is very marked in succulent plants, the contraction and consequent pressure apparently causing the exudation of the uncongealed sap at the cut surface, where it freezes in the form of icicles. In dead wood, soaked in water, there is an evident expansion.

Starch is generally looked upon as a source of sugar in roots, etc., but Herr Boehm states his belief (*Bot. Zeit.*, x., 41) that the starch found in chlorophyll grains is a direct result of the decomposition of carbon dioxide, and can be formed out of sugar and other organic substances. In order to prove his theory, he exposed leaves and pieces of the stem of the scarlet runner containing no starch to the action of a solution of sugar, when they were found after twenty-four hours to contain an abundance of starch, the quantity depending on the concentration of the saccharine solution. In other experiments with the leaves of *Galanthus*, *Hyacinthus*, *Iris*, etc., starch was produced in the same way in from eight to ten days.

In recent works, published by Messrs. Schimper and A. Meyer, on the development of chlorophyll and colour-bearing granules of plants, it is stated (*Nature*, July 19, p. 267) that instead of these bodies being formed free in the protoplasm of the cell, as hitherto supposed, they arise from distinct structures or "plastidia" present in the young cell from its earliest existence, and that any pigment, starch grains, etc., found in connection with the structure named arise by later changes produced by continuous growth and division of the few minute plastidia found in the young cells. Those which are deeply seated and as not yet coloured are called by Schimper "leucoplastidia;" those which are nearer the light and in which a green colouring matter is developed, "chloroplastidia;" and those which in dividing give rise to needle or spindle-shaped bodies or triangular ones with sharply pointed corners, and pass through various shades from green to carmine red, he calls "chromoplastidia" These forms appear to be due to the crystallization of certain of the proteid contents of the plastidia. All the plastidia of the stem and leaves appear to arise by division of the plastidia in the *punctum vegetationis* of the young stem, and those of the root from the division and differentiation of those of the *punctum vegetationis* of the radicle. As they are found at a very early age of the embryo, even when only eight cells old, as in *Linum austriacum*, Schimper thinks it probable that they arise from primitive plastidia in the oosphere. Starch grains may arise from the leucoplastidia, also, at a very early stage, as they may be observed in the oosphere. The Characeæ would seem to be the earliest plants in which all three forms of these bodies occur, the apical cells containing leucoplastidia and the antheridia owing their colour to chromoplastidia.

At a recent meeting of the Linnean Society, specimens of a myrtle wax obtained from the fruits of *Myrica microcarpa*, Benth., from Jamaica, were exhibited by Mr. W. T. Thiselton Dyer, F.R.S. Judging from a specimen presented to the Museum of the Pharmaceutical Society some months ago by Mr. D. Morris, the wax is superior in quality and appearance to any yet introduced into the market, and as the shrub is abundant it could be procured in large quantities. Its introduction is due to the energy and discrimination of Mr. D. Morris, the director of the Botanical Department, who loses no opportunity of drawing the attention of merchants and others to the botanical resources of the island. Mr. Dyer also exhibited Ngai camphor, but appears to have been unaware of Hanbury's paper on the subject in the *Pharm. Journ.*, [3], iv., p. 709.

Lathyrus tuberosus, a rare plant in Britain although not infrequent on the Continent, and supposed to have been the ἀρακώδης of Theophrastus and the Arachos, Aracueda and Arachorides of Pliny, forms the subject of a paper in the *Zeitsch. oest. Apoth-Verein.* (July 20, p. 328). The botany, chemistry, and histology of the root are fully described, and figures are given of its microscopical structure and of the starch contained in it. The author suggests that in view of its possible use as a coffee, these microscopical details might be of use.

According to *Nature* (June 28, p. 212) a description of all the drugs, mostly plants, used in the popular pharmacies of the Government of Karzan and Peru, has recently been published in the 'Memoirs of the Society of Naturalists,' at the Karzan University.

In a recent communication to the Société Nationale d'Acclimatation de France (*Bulletin*, x., 235), M. Paillieux suggests several plants which in his opinion might enter with advantage into the composition of pickles. The first is the Catawissa onion (*Allium fistulosum* var.), which is said to have been introduced into America from China, and appears to be closely allied to what is known in this country as the Welsh onion or stone-leek. It is said to have a flavour *sui generis,* not being precisely that of the onion or of the eschalot. Another plant recommended is the Angourie cucumber (*Cucumis Anguria*, Linn.), a small kind having soft spines which give to it an appearance of a horse-chestnut. Preserved in vinegar it is said to form a beautiful pickle, which is not to be confounded with the insipid vinegar sponges that are usually associated with the name of gherkins. The plant grows wild in the Antilles and different parts of South America, and presents no difficulties in its cultivation. A third plant, which belongs to the Zingiberaceæ, is the Japanese "miôga" (*Amomum Miôga*, Thunb.). In Japan the young stalks and the flowers are eaten, and the author submitted to the Society a sample of pickles prepared from the bulbs of the Catawissa onion and the flowers of the Angourie and Miôga. The tubercles of the tuberous nasturtium (*Tropæolum tuberosum*, R. et P.) were also mentioned as being very good whan used as a pickle, and as having the property of communicating a perfume to the vinegar.

A large amount of attention has been paid during the last twenty years in the Western and North Western States of America to the cultivation of the so-called "Chinese sugar cane" (*Sorghum saccharatum*) as a source of sugar. Up to the present time, however, the results have hardly come up to the expectations formed. The grass, it is true, has yielded a juice which when concentrated formed a rich saccharine syrup; but considerable difficulty has been experienced in obtaining the sugar from the syrup in the crystalline form and free from a disagreeable odour. No doubt this has been mainly due to the unscientific way in which the industry has been carried on. It is therefore satisfactory to learn from a report on the scientific and economic relations of the sorghum sugar industry, recently presented to the United States Commissioner of Agriculture by a committee of eminent chemists and other experts, that the difficulties are now in a fair way of being removed. The report shows clearly that the two essential points on which success depends are the maturity of the "cane" and the prompt and correct working of it. With these requirements satisfied, it is stated that sugar from a field of sorghum may be as surely and safely expected as from a field of sugar cane, and probably with as great a return.

Another portion of the 'Flora of British India,' has just been published, forming the first part of the fourth volume and comprising the plants of the *Asclepiadaceæ*, *Gentianaceæ*, *Boraginaceæ*, *Convolvulaceæ*, *Solanaceæ*, and a portion of the *Scrophulariaceæ*, the last and first named being treated by Sir Joseph Hooker and the remainder by Mr. C. B. Clarke.

In the 'Shakspere Flora,' recently issued, M. Leo Grindon, brings forward arguments to show that the "cursed hebenon" is the yew tree.

In the *British Medical Journal* (June 30, p. 1282) a case of poisoning by hemlock, at Cardiff, is recorded. The plant grows on the ballast tips to the east of Cardiff and was there gathered by a Greek sailor, who boiled it and ate it for supper. Possibly he mistook it for *Anthriscus sylvestris* or *Torilis anthriscus*, both of which are said to be eaten by the Breton onion boys and when stewed with snails are considered quite a delicacy. It would appear that the Umbelliferæ are much more commonly cooked and eaten in continental countries than in England, and that occasionally serious accidents happen in consequence.

Dr. Quinlan's statements concerning the properties of *Galium aparine* have been corroborated by Mr. C. Boyce, of Maidstone (*Brit. Med. Journal*, July 7, p. 14), who states that in a case of cancer in which he recently employed it locally, it diminished the pain so much, that the patient rebuked him for not telling her of it sooner, and that the *Galium* certainly seems to have the power of arresting ulcerative action and promoting a more healthy one. Mr. Quick, of Coventry, also calls attention to the fact that this property of *Galium* was known more than one hundred years ago, for Culpepper, in the 'English Physician,' edit. 1741, p. 93, says of it: "The juice is also very good to close up the lips of green wounds and the powder of the dried herb strewed thereupon doth the same and likewise helpeth old ulcers."

In view of the great anxiety which has been excited in Eastern Europe by the dreadful outbreak of cholera in Egypt, a circular has been issued by Dr. Burkart and Dr. von Jobst calling attention to the specific action of cotoin upon the bowels. For internal administration they recommend the use of an emulsion containing 1 gram of cotoin in 120, a tablespoonful to be taken every quarter or half an hour; or cotoin may be given as a powder in doses of 0·2 gram every half hour or hour. For subcutaneous injection the cotoin should be dissolved in acetic ether (1 of cotoin to 4 of ether), a Pravas' syringeful (equal to 0·2 gram of cotoin) being injected as deeply as possible, not merely under the skin, every quarter hour to every hour. It is important for dispensers to notice that experiments have shown that acetic ether is the only suitable menstruum for cotoin intended for subcutaneous injection.

In an article in the *Lancet* (July 14, p. 56), on the treatment of malignant (hæmorrhagic) scarlatina, Dr. Hayward mentions a remedy under the name of "crotalus," and as pharmacists may consequently be asked to supply the drug, a few details concerning it may prove of interest. Crotalus is a homœopathic remedy prepared from the venom of one or more species of rattlesnake, preferably *Crotalus horridus* and

C. durissus, and is recommended in Hughes's 'Pharmacodynamics' and other homœopathic works in the treatment of hæmorrhagic forms of several zymotic diseases, such as scarlatina, diphtheria, etc., and also as a possible remedy for yellow fever. Considering the improbability that an article on a remedy homœopathically used would be able to find its way into the columns of the *Lancet*, it has been deemed advisable to make an inquiry of the author of the paper as to the identity, nature and doses of "crotalus," and in reply the following details were kindly communicated by Dr. Hayward. The poison is extracted in this country from full-grown rattlesnakes imported alive, the poison-bags being removed while the animals are under the influence of chloroform. As the poison will not keep in its natural state, it is mixed with glycerine as a preservative, since alcohol precipitates the active principle, crotaline. The preparations of the venom are made in the form of decimal dilutions as used by homœopaths, the menstruum in this case being one part of glycerine and three parts of proof spirit. The first decimal dilution is turbid, and requires shaking; it is used chiefly for subcutaneous injection, three or five drops at a time being the usual dose. The third dilution is the one usually prescribed by Dr. Hayward, three drops being given for a dose in a spoonful of water every three hours. The fact that alcohol precipitates the crotaline indicates that it might possibly be kept in the dried state and dissolved in water when required. Few, however, would probably be willing to run the risk of handling or weighing so powerful a preparation. Dr. Hayward is engaged in writing an essay on the properties and uses of crotalus, and fuller information may therefore be shortly expected of a character to interest the medical profession.

The tendency to administer small doses often repeated, in preference to larger doses three times a day, seems to be gaining ground. Dr. Thorowgood, in the *Medical Times and Gazette* (June 30, p. 725), gives the results of his experience with tincture of aconite and solutions of arsenic and strychnia, stating that he finds a dose of one or two minims of tincture of aconite, given every two hours in commencing inflammation, produces better effects than the Pharmacopœial dose of 5 to 15 minims, which is liable to cause faintness. He never exceeds the dose of 3 minims of either Fowler's solution or liquor sodæ arseniatis three times a day, and has had examples of the sudden development of unpleasant symptoms following the use of doses of 5 minims three times daily. He has found that a fiftieth of a grain of strychnia produces excellent results in promoting the restoration of exhausted nerve function, while larger doses add to irritation and eventually increase the exhaustion.

In the *British Medical Journal* (July 7, p. 5), also, Dr. J. C. Uhthoffe states his belief that the solutions of eserine which have for some years been used for contracting the pupil or stimulating the ciliary muscle have been stronger than requisite for the purpose. He generally prescribes one-fortieth of a grain solution to be used three times a day, and only in some cases has it been necessary to increase the strength of the solution in order to produce the effect.

In the course of researches made on the influence of calomel on digestion, Dr. Vainlieff has found that this drug has no influence on the action of the digestive fluids, but entirely prevents those retrogressive and putrefactive changes by which the products of these fluids are rapidly decomposed and micro-organisms quickly developed in great numbers. Calomel when present in the alimentary canal kills bacteria, prevents the butyric fermentation and the formation of indol, etc., which usually appear as a result of prolonged normal digestion, and hinders the decomposition of biliverdin and bilirubin into hydrobilirubin. It is the unaltered character of the two colouring matters of the bile that gives the peculiar bright green hue to fæces passed by patients who have taken calomel. Tyrosin and leucin are, however, found abundantly, these products of pancreatic digestion being evidently preserved unaltered, although in natural circumstances they are so rapidly decomposed that they cannot be detected in semi-digested food (*Brit. Med. Journ.*, July 7, p. 21).

Dr. U. E. Buck, writing to the *British Medical Journal* (June 30, p. 1281) on disinfectants, strongly recommends the use of hyposulphite of sodium of the strength of a saturated solution of the salt mixed with an equal quantity of water. He states that he has failed with sanitas, terebene, resorcin, creasote, boroglyceride, chloride of zinc, charcoal, etc., in allaying the fœtor of cancerous ulcers and keeping them clean, but that he succeeded in doing so with the hyposulphite of sodium.

The use of medicated gelatine as an application in skin diseases has been reported on very favourably by Messrs. Unna and Beiersdorff (*Pharm. Zeits.*, July 18, p. 456, from *Monatsh. f. prakt. Dermat.*). Various medicines are used, of which the preparation of chrysarobin may be taken as a type. It is made by dissolving 50 parts of dry white gelatine in 100 parts of water in a water-bath, then mixing with diligent stirring 10 parts of chrysarobin. The mixture is set aside until cool and preserved in waxed paper. When required for use a small quantity is melted and spread upon the skin with a camel hair pencil; the gelatine soon hardens, and to prevent it from cracking should be painted with a little glycerine. Applied in this way, after a warm bath, the chrysarobin gelatine dressing requires renewal only two or three times a week, even in serious cases of psoriasis.

Some experiments have been made by Dr. Prollius upon a large number of specimens of isinglass, obtained from various sources, in order to clear up the contradictory statements that have been made with respect to moisture, amount of ash, residue, etc. He reports (*Pharm. Centralh.*, xxiv., 336) that the average of ash in the best sorts of isinglass is fairly represented as 0·5 per cent., and the insoluble portion after boiling in water at not more than 3 per cent. A higher proportion of moisture was found in all the samples than is generally expected, the quantity ranging between 17 and 19 per cent. When tested as to the relative viscosity of the filtered solutions, the Russian samples were found to surpass all the others, with the exception of one from Hamburg. Examined under the microscope, after lying for a few days in water, the better kinds all showed a common structure.

According to *New Remedies*, there are in Buckingham County, Virginia, within an area of 10 to 15 square miles, forty distilleries engaged in making sassafras oil. Each mill employs three men and consumes daily 80,000 lbs. of the root, extracting 50 gallons of the oil, or about ½ per cent.

The extraordinary statement made respecting papain by Professor Rossbach to the effect that when injected into the blood it enabled the proto-organisms there present to multiply rapidly, has been called in question by Mr. G. F. Dowdeswell, who has carefully examined papain of German make, and found it to contain a form of bacillus, superficially somewhat similar to a form of the bacillus of hay, which breaks up in dried preparations into very short segments often not above twice as long as broad, like *B. anthracis*, but differing from that species in having rounded, almost acuminated ends, not distinctly rectangular as in that species. Nevertheless, he was unable to find the bacillus in the blood after the papain had been injected into the veins.

The theory usually accepted as explaining the fermentation which takes place in bread-making is that the starch of the flour undergoes hydration under the influence of diastatic ferments with the ultimate production of two glucoses, dextrose and levulose, which in their turn undergo alcoholic fermentation. The correctness of this theory has been recently challenged by M. Chicandard (*Comptes Rendus*, xcvi., 1586), who gives reasons, based upon experimental observations, for considering that the fermentation consists rather in the conversion of a portion of the insoluble albumenoids of the gluten into soluble albumens and afterwards into peptones, the agent of the fermentation being a bacterium that is developed normally in the paste, the yeast playing no other part than to assist in accelerating its development. One part of M. Chicandard's argument was based upon the presumed failure to detect the presence of alcohol during the fermentation; but in a subsequent communication to the Academy of Sciences (*Comptes Rendus*, xcvi., 1865) M. Moussette states that in 1854 the vapour from a Rolland bread oven, condensed upon the metallic plates, yielded alcohol equal to 1·6 per cent. by volume of the crude liquid, 0·06 per cent. of free acetic acid, as well as some combined with iron, and a minute quantity of ammonia.

Several theories have been put forward as to the determining cause of the red coloration of carbolic acid, but none of them has been accepted as quite satisfactory. The observation that the coloration commences in glass bottles in the acid nearest the glass, induced Herr Meyke to make a series of experiments which led him to the conclusion (*Pharm. Zeit. f. Russl.* xxii., 425) that it is due to the presence of lead dissolved from the glass containing vessels. He has demonstrated that carbolic acid is capable of exercising a solvent action upon glass, and not only were lead and other constituents of glass found in a sample of carbolic acid that had become red, but the addition of silicate of lead to an acid that had remained white during eight or nine months was followed by a commencement of coloration on the third day. A qualitative analysis of the glass from two bottles in which carbolic acid had become coloured, revealed the presence of lead, whilst that from two bottles in which acid had remained uncoloured for a long time showed none, though it contained copper which has been alleged to be a cause of coloration. Herr Meyke found that in tinned vessels carbolic acid remains unaltered for a long time, and he recommends that they should be used for the purpose.

Although nine years have elapsed since Professor Dragendorff described sclerotinic acid, a compound that he had isolated while working in conjunction with Herr Podwissotzky and believed to be the active principle of ergot (*Pharm. Journ.*, [3], vi., 1001), it cannot be said that the acid has come into general use; neither, on the other hand, has it passed into the obscurity which would have been its fate ere this had a decidedly adverse judgment been passed against it. This may be partly due to the unsatisfactory form in which it is usually sent out from chemical manufactories, as a strongly-coloured thick extract containing variable quantities of water and liable to change under the influence of air and light. In order to overcome this disadvantage, Herr Podwissotzky has worked out another method of preparing it (*Pharm. Zeit. f. Russl.*, xxii., 393). This consists in heating 400 grams of powdered ergot for three or four hours with a litre of distilled water and 60 grams of dilute sulphuric acid (1 to 7) in a steam-bath, straining and pressing, extracting the residue for two hours with 500 c.c. more of distilled water, and after straining and pressing, mixing the two liquors, heating the mixture to 70° C., and treating it with neutral lead acetate as long as it gives a precipitate, which is an insoluble violet lead compound of erythrosceretin. After retaining the liquid with the precipitate for another hour in the water-bath, it is filtered, lead removed from the filtrate by treatment with sulphuretted hydrogen and filtering, and the filtrate evaporated in the water-bath, or spontaneously to about 150 c.c., or until a brown colour on the margin indicates the commencement of decomposition. The residue is then vigorously stirred with 1½ litre of absolute alcohol, from which the sclerotic acid separates in ten or twelve hours. This alcohol is separated, and the mass is well kneaded with 500 c.c. of fresh absolute alcohol, and then dried over caustic lime and sulphuric acid; by repeating this process the sclerotinic acid can be obtained as a dry, only slightly coloured, powder, the yield being from ten to fourteen grams. It should be preserved over caustic lime and sulphuric acid, or when fresh it may be kept in absolute alcohol. In aqueous solution sclerotinic acid quickly commences to decompose and Herr Podiwissotzky therefore recommends the use of thymol water (1 in 1000) as a solvent. In combination with alkalies or alkaline earths the acid entirely loses its physiological activity.

In a communication to the *Chemical News* (July 6, p. 4), Messrs. Wood and Barrett furnish further information respecting the compound of quinine and quinidine which gave rise to some controversy about eighteen months since. It is described as being obtained in a crystalline form upon mixing ethereal solutions of the two alkaloids obtained by precipitating solutions of the sulphates in acidulated water with sodic hydrate solution in the presence of ether. The numbers obtained upon analysis of the crystals agreed sufficiently well with the formula for one molecule each of quinine and quinidine and two and a half molecules of water. Prismatic crystals were also obtained upon dissolving equal quantities of the two alkaloids in ten times their joint weight of weak spirit with the aid of heat and leaving the solution to crystallize. At first these crystals appeared to contain more than three molecules of water, but after drying over sulphuric acid they approximated closely in composition to those obtained from an ethereal solution. When solutions of the two alkaloids in pure benzene, prepared similarly to the ethereal solutions, were mixed, crystals were obtained which after being exposed in a loosely covered vessel for three days gave results upon analysis that appeared to correspond pretty closely with the formula—

$$C_{20}H_{24}N_2O_2 . C_{20}H_{24}N_2O . 2H_2O + C_6H_6$$

or, one molecule each of quinine and quinidine, two molecules of water and one molecule of benzene. From the fact that the crystals contained water, whether crystallized from ether, weak spirit or benzene, and also because when rendered anhydrous the compound absorbed water from the air, it is inferred that the compound is a hydrate of the two alkaloids. The authors also describe some other analogous compounds. When a warm benzene solution of quinine hydrate alone, prepared by precipitating a warm solution in acidulated water with excess of sodic hydrate in the presence of benzene, was allowed to cool, crystals, at first rhombic, but afterwards tending to become prismatic, were obtained, which appeared to lose benzene by exposure, but when analysed after some weeks gave results that are represented by the formula—

$$2C_{20}H_{24}N_2O_2 . 2H_2O + C_6H_6$$

agreeing therefore in general composition with the compound of quinine and quinidine hydrate crystallized from the same menstruum. When the crystals of quinine hydrate from benzene were redissolved by the aid of heat in pure well-dried benzene, the solution deposited upon cooling, together with the rhombs as before, acicular crystals, which appeared to be a compound of anhydrous quinine, and after exposure gave upon analysis figures corresponding with the formula $C_{20}H_{24}N_2O_2 + C_6H_6$. An analogous compound in acicular crystals was obtained by dissolving 1 part of cinchonidine in 60 parts of benzene at the boiling temperature, and allowing the solution to cool, and the same result was obtained when cinchonidine was precipitated from acidulated water in the presence of benzene. Upon this difference in the behaviour of quinine and cinchonidine when so precipitated, the one crystallizing in rhombs containing the alkaloid, water and benzene, and the other in feathery groups of delicate needles containing only the alkaloid and benzene, the authors have based a test which they state will reveal an admixture of cinchonidine with quinine sulphate, if present to the extent of 1 per cent., after three or four hours, and smaller proportions even than this become perceptible after some days, as the benzene evaporates.

In a preliminary communication (*Pharm. Centralh.*, iv., 325) Herr Beckurts states that salts of strychnine in aqueous solution give with potassium ferrocyanide fine white crystals of ferrocyanide of strychnine, very sparingly soluble in cold water, and with potassium ferricyanide a beautifully crystalline yellow compound, sparingly soluble in cold and more easily soluble in hot water. Upon exposure to air the white ferrocyanide turns yellow, and is eventually completely decomposed, ferricyanide being formed, and a new base which can be extracted with alcohol and has been named "oxystrychnine." The decomposition is represented by the equation—

$$2(C_{21}H_{22}N_2O_2)_4FeCN_6 + O_2 = (C_{21}H_{22}N_2O_2)_6FeCN_{12} + 2C_{21}H_{22}N_2O_3.$$

The same base is formed, together with the ferricyanide, by the action of bromine upon the ferrocyanide of strychnine. Oxystrychnine is soluble in spirit, from which it crystallizes in a hard crust composed of fine needles. Both the hydrochlorate and the hydrobromate of oxystrychnine crystallize in needles, and are more soluble in water than the corresponding salt of strychnine.

Dr. A. R. Leeds (*Phil. Mag.*, xvi., 9) describes a new method for the determination of organic matter in potable water based upon the reducing action of certain organic compounds upon the salts of silver. Some preliminary experiments were made in which (1) 100 cubic centimetres of distilled water free from ammonia were taken and 5 cubic centimetres of a decinormal solution of silver nitrate added; (2) the same as the preceding, but ammonium hydrate added in quantity just sufficient to redissolve the precipitate at first formed; (3) the same as (1) but the silver precipitated as chloride and redissolved by ammonium hydrate; (4) the same as (1) but the silver precipitated as cyanide and redissolved by potassium cyanide; (5) same as (1) but precipitated and redissolved by sodium hyposulphite. These solutions were exposed to sunlight for forty-eight hours and no precipitation was found to result. The above experiments were now repeated, substituting water from the river Schuylkill, which constitutes the water supply of Philadelphia, but which recently had become polluted and possessed an offensive odour and taste. After exposing the solutions made with this water to the light for five hours it was found that the ammonio-argentic oxide was slightly affected, the cyanide of silver and potassium not at all, while the solution of hyposulphite of silver and sodium yielded the largest amount of precipitate, the ammonio-argentic chloride a precipitate nearly as great, and the neutral solution of silver nitrate the smallest quantity. These experiments indicate that the hyposulphite of sodium and silver is the most delicate as an actinic indicator in presence of organic matter, but subsequent experiment showed that a neutral solution of silver nitrate is quite sufficiently delicate. The method proposed for the examination of waters is as follows:—250 cubic centimetres of the water is treated with 10 cubic centimetres of decinormal silver nitrate solution in a stoppered bottle and exposed to light. As soon as the turbidity has aggregated into a precipitate and settled to the bottom, which occupies a time at the most not exceeding two days, it is filtered off, washed with ammonia to remove chloride and the silver weighed, or better, dissolved in nitric acid and the silver estimated by Pisani's method. Dr. Leeds notices many substances that produce similar effects, but believes from his own experience and from that of others that the method is likely to prove serviceable as a process for the determination of organic matter in potable waters. A number of determinations comparing this process with the permanganate method are recorded in the paper.

Dr. Fleming (*Phil. Mag.*, xvi., 48) notices a peculiar phenomenon in connection with the working of incandescent lamps. The Edison lamp, as is well known, consists of a carbon filament bent in horseshoe form, the two extremities of which are held by copper clamps that are connected with the platinum wires sealed through the tube. The ends of the carbon filaments, where they are connected with the copper clamps, are electroplated with copper, in order to ensure a good contact. Should any part of the filament be thinner than another, greater resistance is offered at the thin part and there is consequently here greater generation of heat, by which, Dr. Fleming says, carbon is volatilized and condenses upon the sides of the glass case in a fairly uniform coating. If the point of greatest resistance occurs on the copper clamp, metallic copper is volatilized and deposited upon the glass. In this case, upon examining the glass capsule, it is noticed that there is a narrow line along which no deposition of copper has occurred, which is not the case with carbon. This line of no deposit is found on the side of the glass capsule which is opposite the point from which volatilization has started and is in fact a shadow of the filament. This phenomenon closely resembles similar facts observed by Mr. Crookes in his radiant matter tubes, for the molecules of copper have evidently been discharged in straight lines; but the character of the carbon deposit is rather suggestive of vaporization and subsequent condensation. The copper deposited in the above manner is transparent, and its colour by transmitted light is like that of transparent gold.

The volatilization of carbon, thus once more alleged to take place at a high temperature, is not improbable in itself. Indeed, according to a theory recently put forward by M. Berthelot, who is of opinion that the true carbon is not yet known, if the pure element could be isolated it would be found to be gaseous at ordinary temperatures. On the other hand, it should be remembered that some experiments made by Messrs. Swan and Proctor to determine the nature and cause of the deposit which is sometimes found on the sides of a vessel in which carbon is heated to incandescence by the electric current (*Pharm. Journ.*, [3], x., 605) led them to believe that it consists of particles of carbon that have been mechanically transported by the minute residuum of air in the globe.

Mr. J. Munro (*Phil. Mag.*, xvi., 23) has made some experiments with a metal microphone and also upon its mode of action in a vacuum. The microphone consisted of fine iron wire gauze, one piece of which was stretched between two platinum electrodes sealed in a glass tube, a second piece of wire gauze being hung upon a third electrode and resting lightly against the other piece of gauze. The tube was then fixed upon a base board. When circuit was made with a battery and telephone and a watch placed upon the base board, the ticking was heard in the telephone. The sensitiveness of such a microphone was found to be heightened by bringing a magnet in front of the movable wire gauze, so that by attraction it is drawn slightly away from the piece upon which it rests. When the magnet is brought a short distance from the front of the movable gauze, the ticking of the watch becomes louder, and as the magnet is brought closer, the loudness increases until a certain point is reached, when it ceases and a sharp click in the telephone announces that contact has been broken. If the pole of the magnet be brought up behind the fixed wire gauze the opposite effect it produced, the sounds becoming faint, due to the closer contact of the movable wire gauze with the fixed piece. When the tube was exhausted to the extent of about the millionth of an atmosphere the indications were very marked; in fact, a vacuum microphone of this kind seems to be exceptionally delicate.

GERMS AND EPIDEMICS.

BY JOHN S. BILLINGS.

(*Concluded from page* 52.)

If we consider the diseases caused by minute animals, we find that the one which has the closest analogies with some of the specific diseases is that which is now known by the name of the parasite which produces it, the *Filaria sanguinis*. This parasite, which is found especially in China, India, and some parts of South America, is now supposed to be the cause of that peculiar disease known as elephantiasis, which by older writers was often confounded with true leprosy, and the cycle of its change is a curious one. The mature animal is a worm about the thickness of a hair and from 2 to 3 inches long, which lives in the water. When this gains admission to the human body, usually by being swallowed with drinking water, it seems to penetrate to the lymphatic system, and there to produce eggs from which are developed thousands of microscopic filaria, which swim freely about in the lymph and blood. Under ordinary circumstances they are only found in the blood at night, in the daytime they seem to collect in the lungs and lymph channels, but if the patient be kept awake at night and sleeps in the daytime, this habit is reversed and they are then found in the blood in the daytime only. So long as the microscopic filaria remain in the body of man they do not develop into the perfect animal; for this purpose it is necessary that they should find another habitation, and this is furnished by the mosquito. Having been swallowed by the mosquito with the blood, the embryo assumes a sort of chrysalis state, and at the end of three or four days escapes from its host, which is then dead or dying and has usually fallen into water. You will perceive that there seems to be a very nice adaptation between the nocturnal habits of the parasite and those of the mosquito. Dr. Manson, to whom we are indebted for most of our knowledge of this filaria, estimates that it is to be found in about 10 per cent. of the inhabitants of Amoy, China, its presence causing elephantiasis and various disorders of the lymphatics. Last year a man affected with this disease, which he had contracted in the West Indies, was for six months a patient in the New York Hospital. If any of the celebrated New Jersey mosquitoes got access to him at night and then returned to die in the scenes of their youth, you can see how a new endemic disease might be developed whose progress would be a terrible puzzle if we knew nothing of the filaria. It is also claimed by some observers that malaria and yellow fever are carried and inoculated by the mosquito, but this is yet to be proved. Keeping in mind the limitations of our present knowledge with regard to the causation of disease by minute organisms, and particulate contagion, let us consider briefly some of these acute diseases of communities and nations which are so commonly known as epidemics.

In the popular sense of this word, "epidemic" means that which is prevalent, affecting a large number of people, but it also implies something unusual and temporary. For example, the most widely spread and fatal disease in the United States is consumption, which in the year 1880 caused over 95,000 deaths, or 124·7 per 1000, yet we do not think of consumption as an epidemic disease. Epidemics are commonly divided into the great epidemics or pestilences and the small, local, common epidemics of familiar diseases, but the two forms shade into each other so that it is very difficult to draw any clear distinction. From the earliest times, in all nations of which we have authentic records, there have, from time to time, appeared forms of disease causing widespread desolation and death, when the land seems to rest in the shadow of a destroying angel, who leaves no house in which there is not one dead. There is always a certain element of strangeness about these visitations, which seem to depend on no known causes, and to have been beyond the limits of human power to foresee or prevent. Not that all such epidemic diseases are of ancient origin; new forms occur, and old ones disappear for centuries, but in every generation there comes a time when the sickle of the skeleton reaper seems to have a keener edge, and to take on a wider reach.

Such, for example, was the great outbreak of the plague which began in Egypt in the year 542 of our era, and which spread throughout the Roman Empire, being known as the Justinian Pest. At intervals of one and two centuries this disease reappeared, following nearly the old track, until at last, in the fourteenth century, after a long absence it seemed to have gathered strength, and starting from China, overran Asia, Europe and Africa, or the whole of the then known world, destroying in Europe alone 25,000,000 of people and well meriting its common name of the Black Death, or the Great Mortality. Truly, if this Oriental pest, the sparks of which still linger in the Valley of the Euphrates, be caused by minute organisms, this outbreak is one of the most striking examples in existence of the power of the small things of this world to confound the great. It is impossible for us to realize the scenes which were then enacted in Europe in the frenzied terror which was universal. Hecker's vivid description is no doubt familiar to many of you. "Merchants, whose possessions were unbounded, coldly and willingly renounced their earthly goods. They carried their treasures to monasteries and churches and laid them at the foot of the altar; but gold had no charms for the monks, for it brought them death. They shut their gates, yet still it was cast to them over the convent walls. In Avignon the Pope found it necessary to consecrate the Rhone, that bodies might be thrown into the river, as the churchyards would no longer hold them. The grass grew in the market places, the rooks and ravens came into the towns and built in the belfries, and silence was universal." It is incidentally noted that when the plague had passed away "the great increase of lawyers was astonishing to whom the endless disputes regarding inheritances offered a rich harvest. Then, came also, moral and mental outbreaks, the processions of the Flagellants, the fanatical persecuting of the Jews, and a little later the epidemic mania of the dance of St. John in Germany and the Tarantula dance in Italy."

But I have no time for even the briefest outline of the exceedingly interesting history of the epidemics of the middle ages, and will only refer to one other outbreak, which presents many singularities, namely, the sweating sickness. This disease appeared in England just after the battle of Bosworth Field, in 1483, and rapidly spread over the kingdom. It was a violent fever, followed by a profuse and fetid perspiration, the whole crisis being over in a day and a night. It attacked especially strong and robust men, killing them in a few hours. The whole outbreak lasted about five weeks, and it passed away as suddenly as it came. One attack gave no security against another. The disease again appeared in a mild form in 1506, in a severe form in 1517, and again in 1527 when it spread over Northern Europe. It then entirely disappeared for twenty-three years, when it broke out again in England with its old malignancy, four and twenty hours being decisive of the event. Since the autumn of 1551 the sweating sickness has but once appeared in its rapid and malignant form, and then it was in a very limited area. This was in Roettingen, a small town of Franconia, in the fall of 1802. The visitation was quite characteristic, but it lasted only ten days and ceased with the advent of clear, frosty weather. It is exceedingly doubtful whether the various fevers accompanied by profuse perspiration, which many physicians seek to identify with this disease, such as the Picardy sweat or miliary fever, which first appeared in 1718 and has since that time been frequently observed in France and Northern Italy, have really had any relation to the English disease. One of the peculiarities of the sweating sickness was that it began in Western Europe and spread eastward, whereas almost all the great plagues came from the East—from Egypt and far Cathay—for which there was supposed to be some mysterious reason connected with the birthplace of the human race. When, however, we remember that until within a very recent period the civilized world, which alone preserves intelligible records, was confined to the West of Europe, so that epidemics of external origin must almost necessarily have come from the East, and, moreover, that in that East was a swarming population, poor, overcrowded, filthy, and specially liable to famine, which is the great forerunner of pestilence, there seems nothing remarkable in the course taken by epidemics, which, as a rule, follow the lines of travel. This portability of the cause of epidemics, its "portagiousness," as Dr. Gibbs proposed to call it, is a very striking feature of many of the spreading diseases, and is a strong argument in favour of the proposition that this cause must be something which is material and which is not a gas. It is, in fact, extremely difficult to explain the well-authenticated instances which we have of the introduction of yellow fever into a place by means of infected bedding or clothing and its steady spread thereafter, in some instances keeping on one side of the street and passing from house to house with the regularity of a postman, at the rate of about 40 feet a day, unless we assume that this poison is not only material and solid, but living, that it may grow and increase outside the body. The old farmer's remark that "Yellow Jack can't go anywhere unless you tote him" is quite true for distances of a few miles, but for a few squares only he seems to be able to get along without assistance.

The sudden development and cessation of some epidemics, such as the sweating sickness, are sometimes urged as being opposed to the idea that living organisms can be the cause of such phenomena, but we have some well-observed facts in relation to the sudden development in large numbers of rare and remarkable fungi, or of certain insects, such as the potato bug, the grasshopper, or the phylloxera of the French vineyards, to prove that this is not an unprecedented thing. It is, however, by no means true that all epidemics can be supposed to spread in this manner. Take, for instance, influenza, of which more than ninety epidemics have occurred since its first accurately recorded appearance in 1510. Usually the epidemic wave of this disease travels with great rapidity from the North and East towards the West and South, affecting the great majority of the population in its path. It does not follow the lines of travel; when it reaches a place it strikes the whole at once, and there is nothing about it which would indicate that it is in any way dependent upon germs; on the contrary it would seem that its cause must be either gaseous or some form or variation of force.

Cerebro-spinal meningitis, which is one of the new epidemic diseases of the century, also approaches influenza in its pandemic character and in the difficulty of explaining its phenomena by any form of the germ theory.

Twice it has broken out simultaneously in this country and in Europe, it is certainly not contagious, and we are almost totally ignorant of the conditions under which it appears, spreads, or disappears. The only theory which will fit influenza and crebro-spinal fever is the famous one of epidemicity, or the epidemic constitution, which, as given by most writers, has a painful resemblance to the explanation given by the bachelor in *Le Malade Imaginaire*, who, when asked how opium produces sleep, replied that it is by a certain sleep-making faculty which it possesses.

An improvement on the epidemic constitution is the theory of Dr. Robert Lawson, who supposes that in connection with periodical variations in the magnetism of the earth there are formed on the Southern hemisphere what he calls pandemic waves, which pass from South to North occupying four or five years in travelling from the Cape of Good Hope to the Irish coast. The passage of this wave gives rise to malarial fever in India, the pest in

Asia, yellow fever on the tropical Atlantic coasts, typhus in Germany, typhoid in France, and relapsing fever in Ireland. This idea is varied and improved upon by Mr. Cushing, who, in a paper published in the *International Review* in 1880, supposes that famines and epidemics depend on changes in the sun, indicated by the so-called sun-spots which have a cycle of a little over eleven years. It is probable that there is some truth in this idea, which is quite compatible with the germ theory, but the table which he gives to show the concidences of maximum sun-spots and epidemics is something like one of Mr. Vennor's almanacs, it being usually possible to find some kind of an epidemic at some point of the earth's surface within any period of two years. The resemblance to Canadian meteorological prophecies is also seen in the fact that Mr. Cushing predicted epidemics in 1882 to accompany the maximum sun-spot period of that year, and that the said epidemics failed to appear. The great objection to all theories of this kind is that they lead the persons who uphold them to overlook or deny the existence of causes much more comprehensible and which can be practically dealt with. First of all there is the influence of contagion, which is almost always denied by these theorists. Then there is the influence of the seasons, of uncleanliness, of famine, of poverty and misery in a thousand ways. It is true that none of these will explain the phenomena of some epidemics; why it is that cholera or yellow fever will sometimes spread like a fire in the dry grass, and again are stamped out with ease; why scarlet fever is the English pest, and typhoid that of Paris; or why small-pox should at times show a special virulence. But at all events we gain nothing by giving up the problem as insolvable or referring it to an epidemic constitution or a pandemic wave.

Each epidemic is a problem by itself, and when carefully studied it is usually possible to determine some of its causes at least, if not all of them. The recent discoveries in the life history of some of the micro-organisms to which I have called your attention, the fact that variations in nutriment, temperature, air supply, and stage of growth at which propagation takes place, may convert one of the most harmless of microphytes into one of the most deadly, seem to give us a clue to the explanation of many phenomena in epidemiology heretofore deemed most mysterious.

We must also bear in mind the powers of natural selection, not only as it affects the germ but the recipient of that germ, if we are to understand the periodicity of these affections.

Even in the midst of the most terrible epidemic there are always some who resist its influence, and when it has passed away these are the survivors who transmit some of this power of resistance, with other peculiarities, to their descendants. Where one attack of the disease confers, in case of survival, protection against the second attack, it is easy to see why there should be long intervals of absence of such diseases from a community; but the same follows in a less degree by the laws of natural selection and heredity, even when the disease is one which may recur.

Small-pox still causes great alarm when it appears amongst us, but we can hardly realize the feelings with which it was viewed in the last century throughout Europe. There were published last year some extracts from a register kept from 1728 to 1764 in Kilmarnock, Scotland, a town at that time of between four and five thousand inhabitants.

From this it appears that small-pox came round regularly about once in five years. Each epidemic affected all or nearly all who were not disease proof, and therefore its victims were almost entirely children under five years of age, who had come into existence since its last visit.

Those who recovered were disfigured for life. There were, in fact, says Dr. McVail, three Kilmarnocks. One had no fear of small-pox, for its people had already met it. Some were blind, some were deaf, most were scarred and disfigured. The second Kilmarnock was under the green sod of the churchyard. The third Kilmarnock consisted of a band of about five hundred little children, which had yet to face the most terrible enemy it would ever meet. "One can barely imagine what must have been the feelings of a mother during these visitations. Even when the town was free from pestilence there would be the constant foreboding of its all too certain coming, and when at last the first case occurred, when the doctor was called in and pronounced the disease to be small-pox, his words would be heard as a sentence of death to some member of almost every family containing little ones." One of the peculiarities of the great epidemics is that they are often preceded by an unusual prevalence of diseases having somewhat similar symptoms, although quite distinct from the true pestilential affection; thus bowel affections precede cholera, malarial diseases yellow fever, and typhus the true plague; and it is for this reason sometimes extremely difficult to discover the first cases of the epidemic, and to fix the precise date of its commencement.

It is important to remember also that the mere introduction of germs into the living organism does not ensure their multiplication, or the production of disease. The condition of the organism itself has much influence on the result. Some persons cannot be vaccinated successfully; many persons can be vaccinated successfully at one time and not at another; some persons do not contract diphtheria or scarlatina or yellow or malarial fevers, although fully exposed to their causes. Pasteur has certainly made a hasty generalization in declaring that the only condition which determines an epidemic is the greater or less abundance of germs.

I hope that as I have indicated a few of the many points upon which our knowledge with regard to these disease germs is still imperfect, it has occurred to you that some of these could be settled by experiment; and that you have felt a certain degree of impatience on learning that these experiments have not yet been made, and that we must still suspend judgment.

I hope also that you may appreciate the importance of having these researches made, that they should be made for the benefit of the world, and when I tell you that the governments of England, France and Germany are employing the best talent they can get and furnishing money for this purpose, while your own country has stopped a series of most promising investigations of this kind, which were being carried on by some of our most competent scientfic men, and has deliberately resolved to confine national public health work to paying bills of quarantine inspectors *after* the epidemic has made its appearance, I think you will feel a certain sense of—well, never mind what it is a sense of—but I think you will feel it all the same. I find, however, that I am on the verge of making some "practical" remarks which I wish carefully to avoid.

At all events we have learned enough to know that the life which is born of, and nourished in, death and corruption may become the cause of disease and death in higher organisms, and that, too, to an extent in comparison with which the ravages of war sink into insignificance.

The possibilities which exist in one of these tiny crystal rods or spheres we have as yet only begun to comprehend, but as we come to understand them, the wonder seems to be, not that so many die, but that so many of us are left alive.

Yet, if we turn from limited localities and consider the life of the great races of the earth, we find that everywhere the gain is greater than the loss, though nowhere is it so great as in our country.

If we suppose that each of the little crimson discs which keep up a ceaseless waltz through the blood vessels of the growing boy has individual consciousness, we can imagine that their views of their environment and its probable future might be by no means clear. They see new corpuscles entering the dance every moment—from whence they know not—and, in a little time, they are disintegrating and passing away. It seems like an enormous waste of generative and formative force, but by and through this apparent waste the boy becomes a man. In his turn he plays his little part in the development of the race and goes over to the majority.

In the words of the 'Rubayat'—

"'Tis but a tent where takes his one day's rest
A Sultan to the realm of Death addrest;
The Sultan rises, and the dark Ferrash
Strikes and prepares it for another guest.

"And fear not lest Existence, closing your
Account and mine, should know the like no more.
The Eternal Sâki from that Bowl has poured
Millions of Bubbles like us, and will pour."

CEYLON GAMBOGE.

A correspondent of the *Weekly Ceylon Observer* inquires why gamboge should not be collected in Ceylon. He points out that fifty years ago Dr. Pereira described the colour of Ceylon gamboge as excellent and its medicinal effect as precisely the same as that of Siam. Dr. Pereira speaks of two kinds, the goraka and the *kana* (Sinh. "eating") groaka, and says further that "there seems to be no difficulty in obtaining the gamboge in a pure state, and if so it might become an article of commerce from Ceylon." Although this was stated in 1832, Ceylon gamboge has not yet become an article of commerce. The correspondent adds that Pereira's statement that there are two kinds of goraka is a mistake. There are as many varieties as regards shape of leaf, colour of flower and fruit, and shape, size and flavour of fruit, as there are af mangoes, plantains and all other fruit. The varieties hardly deserve botanical distinctions. The coarse gamboge sold in the bazaars is not what is collected in Ceylon, but is imported from Southern India. What is collected in the island is never sold. It is used sometimes by the Buddhist priests to dye their robes, a mixture with sapan dye, giving thus brownish yellow or yellowy brown which distinguishes the robes of the Amarapura sect of priests. It is used also to colour mats, for painting walking sticks, spears and bones, doors and walls of temples, etc. The mangosteen (*Mangostana cambogia*) belongs to the same or similar family, and from the rind of the green fruit, particularly, the gamboge flows abundantly on mere pressure. There are some of the Ceylon gorakas yielding fruit quite as delicious for eating as the mangosteen. The half-ripe rind of some of the Ceylon varieties is dried and sold in the bazaars for pickling fish with. It has a peculiar sharp acid flavour. There is a variety grown in fruit gardens known as the *rata* (foreign) goraka. The fruit is quite yellow when ripe and like the mangosteen round with a smooth surface, but the rind is soft, not leathery or rough. The seeds of this kind are, like the mangosteen and goraka, covered with a pulp, not white but yellow in colour, and, though sweet, quite different in flavour from that of the mangosteen or goraka. The tree resembles the mangosteen but is smaller in size. The leaves are as large but of a darker green and with a greater droop. Can this be the *Garcinia Hanburii* of Siam? It is not a favourite fruit. When ripening it is picked and pickled in vinegar, the seeds being removed and the fruit stuffed with other pickled fruit, etc., finely chopped. It seems that the goraka was considered of such little value that immense numbers have been felled from private and Crown lands and supplied to the railway as fuel. Measures should be taken to stop this wasteful destruction. As regards the mode of collection, the writer thinks it is very doubtful if the stick gamboge is collected by bamboos being placed below incisions in the tree for the liquid to flow into. The liquid exudes very slowly and dries too soon to flow. The peculiar marks in the stick gamboge are usually attributed to the inner formation of the bamboo in which it is collected, but he is inclined to think it is the result of the daily additions of the semi-dried liquid put in as soon as it is *scraped* off from the tree. The few natives who gather it do exactly as was described by Colonel and Mrs. Walker in 1839. A piece of bark from the trunk, about the size of the palm of the hand, is cut off and the resin scraped off it next morning. By boiling the leaves, the rind of the green fruit, etc., a gamboge, inferior only as a colouring matter, is obtained, but with care and using the scraped and clean bark only, gamboge as a dye-pigment ought to be obtained in this way too. The goraka tree is now scarce in the Central Province owing to its destruction when the forests were felled for coffee. But countless numbers yet remain in the island along the western coast from north to south. It would, however, be difficult for Europeans to set about collecting the gamboge, as the trees are so scattered over the country. A group of five to ten trees together in a plot is rarely found.

CHRYSOPHANIC ACID.*

The substance usually called chrysophanic acid, which has played a considerable *rôle* during the last few years as a local remedy in certain skin diseases, is more correctly called *chrysarobin.* It is a substance separated by certain solvents from goa powder, a substance found deposited in the wood of the trunk of *Andira araroba*, Aguiar. This commercial chrysarobin may be converted, by oxidizing agents, into true chrysophanic acid, and it frequently contains traces of the latter body, but it should *not* be designated by the name "chrysophanic acid."

True chrysophanic acid was discovered in 1819 by Schrader, in a lichen, namely, *Parmelia parietina*, Ach. It was first prepared pure by Rochleder and Heldt in 1843, and was subsequently met with in another lichen, viz., *Squamaria elegans*; also in the roots of various species of Rheum, particularly the officinal rhubarb, and in the leaves of various species of Rumex and Cassia.

According to Kubly, rhubarb contains only a small quantity of the acid ready formed; a larger amount is obtained by treating rhubarb so as to split up the glucoside chrysophan.

It may be prepared in the following manner. Powdered rhubarb is exhausted with very dilute alcohol containing some potash in solution, and the expressed and filtered liquid saturated with carbonic acid gas; the resulting precipitate is redissolved in 50 per cent. alcohol containing some potash, and, after filtration, precipitated by acetic acid. The last precipitate is dissolved in boiling alcohol (strong), the solution filtered hot and then mixed with water. This causes the separation of chrysophanic acid in yellow flakes. It may be purified by repeated crystallization from alcohol, or more completely, by precipitating the alcoholic solution with acetate of lead, depriving the filtrate of lead by means of sulphuric acid, and precipitating it by the addition of water. In this case it should also be further purified by recrystallizing it several times from alcohol.

Warren de la Rue and Müller recommend exhaustion of powdered rhubarb, which has been soaked in cold water and again dried, with benzol, in a displacement apparatus. On distilling off the benzol from the percolate, the residue congeals, on cooling, to a crystalline magma, which is pressed and again dissolved in boiling benzol, while an accompanying reddish-yellow substance (emodin) remains partly undissolved, partly separates from the solution during the cooling. The filtrate is evaporated to the crystallizing point, and the crystals purified by repeated crystallization, first from benzol, then from glacial acetic acid or alcohol.

Concerning the *therapeutic* effects of chrysophanic acid, the statements are quite contradictory. According to Schlossberger (*Ann. Chem. and Pharm.*, 66, 83), the acid prepared from *Parmelia parietina* has no purgative action, and that prepared from rhubarb was found to be inert,

* From *New Remedies.*

even in doses of ½ gram, according to Buchheim. On the other hand, Schroff noticed, after a dose of ½ gram of the pure acid from *Parmelia*, eructations and slimy stools, which latter commenced about twenty-four hours after taking the dose and continued to the fifth day, accompanied by want of appetite, oppression of the head, dizziness and lassitude. Schlossberger denies the transition of the acid into the urine, and ascribes the yellow colour of the latter, after rhubarb has been taken, to phæoretin and erythroretin. Schroff and Buchheim, however, noticed yellowness of urine regularly after each administration of the acid, even up to the eighth day, and Meykow asserts that the rhubarb-resins colour the urine only if contaminated with chrysophanic acid. The purgative effect of rhubarb can evidently not be ascribed to the small quantity of chrysophanic acid present, and only in part to phæoretin (which purges only in larger doses).

All other therapeutic statements, which have appeared in late years, concerning chrysophanic acid, refer to chrysarobin from goa powder.

INDIARUBBER COLLECTION IN BRAZIL.*

In the early morning, men and women come with baskets of clay cups on their backs, and little hatchets to gash the trees. Where the white milk drips down from the gash they stick their cups on the trunk with daubs of clay, moulded so as to catch the whole flow. If the tree is a large one, four or five gashes may be cut in a circle around the trunk. On the next day other gashes are made a little below these, and so on until the rows reach the ground. By eleven o'clock the flow of milk has ceased and the *seringueiros* come to collect the contents of the cups in calabash jugs. A gill or so is the utmost yield from each tree, and a single gatherer may attend to a hundred and twenty trees or more, wading always through these dark marshes, and paying dearly for his profit in fever and weakness. Our *mameluca* hostess has brought in her day's gathering—a calabash full of the white liquid, in appearance precisely like milk. If left in this condition it coagulates after a while, and forms an inferior whitish gum. To make the black rubber of commerce, the milk must go through a peculiar process of manufacture, for which our guide has been preparing. Over a smouldering fire, fed with hard nuts of the *tucuma* palm he places a kind of clay chimney, like a wide-mouthed, bottomless jug; through this *boiao* the thick smoke pours in a constant stream. Now he takes his mould—in this case a wooden one, like a round-bladed paddle—washes it with the milk, and holds it over the smoke until the liquid coagulates. Then another coat is added, only now as the wood is heated, the milk coagulates faster. It may take the gatherings of two or three days to cover the mould thickly enough. Then the rubber is still dull white, but in a short time it turns brown and finally almost black, as it is sent to the market. The mass is cut from the paddle and sold to traders in the village. Bottles are sometimes made by moulding the rubber over a clay ball, which is then broken up and removed. Our old-fashioned rubber shoes used to be made in this way. Twenty million pounds of rubber, valued at 6,000,000 dollars, are annually exported from Pará in the dry season; many thousand people are engaged in gathering it. But the business altogether is a ruinous one for the province, as Brazilians themselves are fully aware. The *seringueiro*, who gains two or three dollars for a single day's gathering, has enough, as life goes here, to keep him in idleness for a week; and when his money is spent, he can draw again on his ever-ready bank.

The present wasteful system is spoken of as follows:—The half-wild *seringueiros* will go on submitting to impositions and dying here in the swamps, until Brazilians learn that by purchasing this land from the Government, and planting it in rubber trees, they can insure vastly larger profits, and do away with the evils of the present system. It is what must eventually be done. The rubber gatherers, in their eagerness to secure large harvests, have already killed an immense number of trees about the Pará estuary; they have been obliged to penetrate farther and farther into the forest, to the Tocantins, Madeira, Purus, Rio Negro, and eventually even these regions must be exhausted, unless they are protected in some way. The trees, properly planted and cared for, will yield well in fifteen years, and, of course, the cost of gathering would be vastly reduced in a compact plantation; half the present labour of the rubber collector consists in his long tramps through the swampy forest.

* From the *Dominica Dial*.

INLAND PARCELS POST.

The Inland Parcels Post will commence on Wednesday the 1st of August, on and from which day parcels *not exceeding 7 lbs. in weight* will be received at any post office for transmission between places in the United Kingdom.

In order that a packet may go by Parcels Post it must be tendered for transmission as a parcel, and should bear the words "Parcels Post,"—which should be clearly written in the left-hand top corner.

Every post office will be open to the public for Parcels Post business on week days during the same hours as for general postal business. No Parcels Post business will, as a rule, be transacted in England or Ireland on Sundays, Christmas Days, and Good Fridays; nor in Scotland on Sundays and Sacramental Fast-days.

The following are the principal conditions and regulations:—

The size allowed for an inland postal parcel will be—

Greatest length	3 ft. 6 in.
Greatest length and girth combined	6 ft. 0 in.

For example—

A parcel measuring 3 ft. 6 in. in its longest dimension may measure as much as 2 ft. 6 in. in girth, *i.e.* round its thickest part; or—

A shorter parcel may be thicker; thus,—if it measure no more than 3 feet in length, it may measure as much as 3 feet in girth, *i.e.*—round its thickest part.

The most convenient mode of measuring will be by means of a tape 6 feet long, having the length of 3 ft. 6 in. marked thereon. So much of the tape as is not used in measuring the length will be the measure of the maximum girth permissible. Such a tape, if provided by stationers, might conveniently be marked in one colour up to 3 ft. 6 in., and the remaining portion in another colour.

The rates of postage will be,—for a parcel:—

Not exceeding 1 lb. in weight.	3*d.*
Exceeding 1 lb. and not exceeding 3 lbs. .	6*d.*
,, 3 lbs. ,, ,, 5 lbs. .	9*d.*
,, 5 lbs. ,, ,, 7 lbs.	1*s.* 0*d.*

No parcel will be accepted which weighs more than 7 lbs., or is not sufficiently paid. The postage must, in all cases, *be paid in advance*, and by ordinary postage stamps, which must be affixed by the sender before tendering a parcel for transmission by Parcels Post at a post office.

Posting of Parcels.—Parcels must not be posted in a letter box, but must be taken into a post office and handed over the counter. Care must be taken that every parcel bears a clear address.

If a parcel be posted in a letter box it will not be forwarded by Parcels Post, but will be treated as a letter, or as a book packet if it can pass under Book Post regulations.

The address of a parcel must be clearly written, either on the outer wrapper or on a separate address label securely fastened to the parcel; and the necessary stamp or stamps, to prepay the postage, must in all cases be placed (as in the case of letters) close above the address.

Forbidden Articles; Treatment of Perishable and

Dangerous Articles; and Parcels which must be refused.—Parcels which bear on the outside any writing or drawing of an indecent or offensive nature, or within which any contents of a like nature may be observed, and parcels containing gunpowder, cartridges, lucifer matches, or anything explosive or liable to sudden combustion, bladders containing liquid, live animals, grossly offensive or filthy matter, and anything in a condition likely to injure other parcels, or any officer of the Post Office, are prohibited.

If any such parcel be tendered for posting, it will be refused, or, if detected in transit, it will be detained.

Parcels containing fish, game, meat, eggs, etc., or razors, scissors, needles, knives, forks, or other sharp instruments, will not be accepted unless securely packed so as to guard against risk of injury to other parcels. Liquids, or semi-liquids, such as jellies, pickles, paint, varnish, etc., will not be accepted unless in bottles or cans securely stoppered; nor powders unless so packed that they cannot escape in transmission. Bottles, or glass in any form, will be accepted only when so packed as to be secure from breakage. If a parcel be tendered in a damaged or insecure condition, or in a condition likely to injure other parcels or any officer of the Post Office it will be refused. If a parcel in such condition should be observed in transit it will, if possible, be made secure and sent forward; but, if it cannot be so secured, it will be detained.

Parcels known to contain a letter, packet, or parcel intended for delivery at an address other than that borne on the parcel itself, are prohibited.

Parcels to and from the Channel Islands and the Isle of Man.—Parcels addressed to the Channel Islands (Jersey, Guernsey, Alderney, Sark, and the adjacent inhabited islets) will be received from the public under the same general conditions with regard to weight and size, and at the same rates of postage, as parcels for all other portions of the United Kingdom; but as the Channel Islands, in relation to the Customs laws of the United Kingdom, are subject to the same restrictions as foreign countries, such parcels will be liable to Customs examination at the port of arrival, and the sender will be required to make a declaration of contents upon a special form provided for the purpose at the office where the parcel may be posted.

Goods intended to be warehoused in the Channel Islands, or on which it is intended to claim "drawback" of duty on subsequent exportation from the Channel Islands, will not be accepted for transmission by Parcels Post.

Parcels for the Isle of Man will be treated in all respects in the same way as parcels for places in the United Kingdom generally. They will be liable to examination by the officers of Customs; but the sender is not (as in the case of the Channel Islands) called upon to furnish a declaration of contents.

☞ The Customs laws of the United Kingdom do not admit of the use of the Parcels Post for the introduction into Great Britain of tobacco in any form.

Parcels addressed to a Post Office to be called for.—To those post offices to which letters may be addressed to be called for, parcels may also be addressed to be called for.

There is no private box delivery of parcels, but parcels may be obtained, as follows, on application at a post office, provided the postmaster is satisfied of the identity of the applicant:—

1. By persons having parcels addressed to a post office.
2. By persons not residing within a free delivery.
3. By persons residing within the free delivery of a head office, or of any rural post, so far as regards parcels for which there is no immediate delivery by the usual means.
4. By members of the military, naval, constabulary, and coast guard services, under the same rule as applies to the delivery of their letters.

Parcels addressed to a post office to be called for, or to a person residing beyond the free postal delivery, will be kept three weeks.

Parcels addressed to a ship will be kept one month.

If, however, such a parcel contains perishable matter it will be kept only forty-eight hours; and should it become offensive it may be disposed of at any time as the Postmaster-General may direct.

Parcels liable to Demurrage.—Parcels addressed to a post office "to be called for," and only such parcels, are liable to a demurrage (detention) charge, if not called for within a certain time, at the rate of 1*d.* a day after they have remained in the office one clear day, counting as a day the period during which the office is ordinarily open to the public.

Thus a parcel arriving after the opening of the office on a Monday becomes liable to demurrage if not called for before the closing of the office on Tuesday night, and if delivered on Wednesday the charge will be 1*d.*: one penny being added for each succeeding day, or part of a day.

No charge will be made in respect of Sundays, Christmas Days, Good Fridays, or Bank Holidays, in England or Ireland; nor in respect of Sundays, Bank Holidays, and Sacramental Fast-days in Scotland.

No demurrage will be charged on parcels addressed to persons residing outside the limits of the free delivery, or to persons on board ship.

Re-direction of Parcels.—On receipt of a properly signed authority, a parcel may be re-directed under the following regulations:—

If the re-direction be from one place to another within the same delivery, the parcel, not having been delivered, and being re-directed by an officer of the department, is liable to no charge for re-direction; but if re-directed by any person other than an officer of the department, or to an address in another delivery, it is liable to additional postage at the full prepaid rate for each re-direction. If it has not been delivered and is re-directed by an officer of the department, prepayment for re-direction is not compulsory, but a parcel which has been delivered as addressed will not be accepted for re-transmission unless the postage for re-direction be prepaid.

Returned Parcels.—In order to facilitate the return of parcels which cannot be delivered it is most desirable that the name and address of the sender should appear on the outside of every parcel.

If a parcel which cannot be delivered bears on the cover the name and address of the sender a printed notice will be sent to him by post informing him that the parcel (if not claimed in the meantime by the addressee) will be given up to him or to to any person whom he may direct to call for it or will be returned to him by post.

If the parcel should be called for by the sender or his agent, or if it should be returned to him by post, it will be liable to a charge of one penny for each day or part of a day after the expiration of two clear days following that on which the notice has been sent.

If the sender should elect to have the parcel sent back to him by post he must return the printed notice with stamps sufficient to cover new postage at the full rate and also to cover any other charges to which the parcel may be liable, including the charge of one penny a day described above. The parcel will then be forwarded to him prepaid by stamps affixed thereon.

If no reply be received within six days after the date of the notice, or if the postmaster should have reason to believe that application is made for the parcel by a person who is neither the sender nor the addressee nor duly authorized by either, or if the sender fail to pay the charges due on the parcel, the parcel will be sent to the Returned Letter Office.

If a parcel which cannot be delivered does not bear on the cover the name and address of the sender it will be sent to the Returned Letter Office where it will be opened and examined.

If upon such examination the name and address of the sender are ascertained a printed notice such as is described above will be sent to him, and the parcel will be treated in the same manner as a parcel upon the cover of which the name and address of the sender appears.

If the name and address of the sender cannot be ascertained from the examination of the parcel the name of the addressee of such parcel and the post office at which it was posted will be entered on a list, which will be exhibited in a conspicuous position at the Returned Letter Office of the district for inspection by the public.

Personal applications for parcels entered on such lists will be entertained for three months from the date of entry, after which the parcels will be finally disposed of.

Parcels without Address.—Parcels found without addresses will be sent at once to the proper Returned Letter Office.

Parcels found to contain dangerous or offensive matter will be detained.

Rural Carriers forbidden to collect Parcels from the Public.—Rural letter carriers on foot are forbidden to collect parcels from the public. Mounted rural carriers are also forbidden to collect parcels from the public except under special authority.

Delivery of Local Parcels by Mounted Rural Carriers.—A parcel handed by the public to a mounted rural carrier authorized to collect parcels will be delivered either on his outward or inward route, provided it shall first be taken to a sub-office in order that the stamps may be defaced.

Parcels above Weight or Size, or Insufficiently Paid.—Should a parcel exceeding the prescribed limits of weight and dimensions be accepted by a mounted rural carrier or mail driver authorized to collect, it will be stopped at the office at which he hands it in and returned to the sender by the person who accepted it. Should a parcel be accepted with insufficient postage, stamps for the amount of the deficient postage will be affixed to the parcel, which will be sent on to its destination, and the amount will be charged against the person who so accepted it and who will have to collect it from the sender.

Parcels not to be Accepted near a Post Office.—Mounted rural carriers or mail drivers, even when authorized to collect, may refuse to accept parcels tendered to them close to a post office.

Rural Letter Carriers not to carry Parcels on their own Account.—Rural letter carriers or parcels carriers, on foot, are forbidden to carry parcels of any kind on their own account. In certain exceptional cases, in which special permission has been given to carry newspaper parcels, this rule will not be enforced as regards such parcels.

Newspaper Parcels carried by Horse Posts.—Mail cart contractors or their drivers and mounted rural carriers may carry on their own account parcels of newly published newspapers, addressed to a newsagent, without restriction of weight, so long as the carrying of such parcels does not interfere in any way with the due performance of the mail service; but they are not allowed to carry on their own account parcels of any other description except in cases where they hold a special authority to do so, and such authority will in no case include parcels which are within the limit of weight prescribed for postal parcels.

Parcels by Passenger Conveyances.—Contractors for the carriage of mails by passenger conveyance are not subject to any restriction as to the parcels they may convey.

Detention of Parcels under Special Circumstances.—The Postmaster-General has power to delay parcels when it is necessary to do so in order to secure the due despatch of the letter mails, or when it is expedient for the safety and protection of parcels mails. When, therefore, a postmaster is satisfied that the despatch or delivery of letters would be delayed by the despatch or delivery of parcels, such parcels, or any of them, may be detained until the following despatch or delivery; or if it be necessary for the safety and protection of parcels that any of them should be forwarded or delivered by a later despatch or delivery than that for which they were intended a postmaster may delay such parcels, or may make some special arrangement for the despatch or delivery thereof, such as he may deem necessary or expedient in the circumstances of the case. In no case, however, must the delay exceed twenty-four hours.

Private Bags.—Postmasters are not prohibited from enclosing parcels in private bags, but under no circumstances will the restriction as to the weight of a private bag when empty be relaxed

A Parcel not to be given back to the Sender.—The rule forbidding that a letter should be handed back to the sender applies equally to a parcel.

Bankrupts' Parcels.—The Post Office rules which apply to bankrupts' letters apply equally to bankrupts' parcels.

Deception as to Place of Posting.—Postmasters are forbidden to be parties to deceiving the addressee of a parcel in regard to the place of posting.

If a parcel reaches a post office under cover with a request that it may be posted it will be endorsed according to the rule applicable to a letter similarly received. If the parcel bears the necessary postage it will be forwarded as addressed. Should the postage not be prepaid the parcel will be sent to the Returned Letter Office.

Damaged Parcels.—A parcel found open or in a torn or injured condition will be re-fastened as carefully as possible and secured with an official seal, or by means of a label similar to those provided for securing torn letters, and initialled by the responsible officers.

Non-Liability of Postmaster-General.—The Postmaster-General is not liable to make good any claim in respect of lost or damaged parcels.

Gratuities.—The Post Office regulations which apply to the solicitation of gratuities from the public by persons employed in the postal service applies to persons engaged in parcels work.

Suggestions.—(*a*) Mercantile firms and others who may have to post a large number of parcels at one time will facilitate the despatch of the parcels by sending them to the Post Office in batches, and as early as possible.

(*b*) The risk of delay in the transmission of parcels will be largely obviated if senders of parcels in large quantities (whether it be the intention to post the parcels daily or at regular or irregular intervals) will so far as possible notify their intentions to the nearest postmaster or sub-postmaster as early beforehand as convenient. It is not essential that the number and weight of the parcels and the frequency of posting should be specified with absolute precision: it will be sufficient if a general idea be given so that some provision over and above the ordinary means available may be arranged for in advance.

(*c*) The public will greatly assist the work of the Post Office and help towards the safe delivery of parcels by taking care that they are in all cases strongly and securely packed, especially those with fragile or perishable contents. It must be borne in mind, although of course every care will be taken by the officers, that such a parcel must be several times handled before it reaches its destination, and will probably have to be packed with many others of a different kind and shape, or more weighty and bulky.

(*d*) It is not intended to apply to postal parcels the practice which obtains of adding to the address in the case of letters for the Metropolitan district the postal district initials, and such initials should not be used in addressing a parcel to London or the suburbs.

By command of the Postmaster-General,

S. A. Blackwood, *Secretary.*

General Post Office,
July, 1883.

The Pharmaceutical Journal.

SATURDAY, JULY 28, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PATENTS AND TRADE MARKS.

ONE very important measure which has passed the ordeal of the Standing Committee on Trade, and now awaits the consideration of the House of Commons, is the Government Bill to amend and consolidate the law relating to patents for inventions, trade marks, and registration of designs. Many previous attempts have been made to legislate upon these matters by independent members without success, but in the present Bill the subject appears to have been dealt with comprehensively, and on the whole acceptably, by the President of the Board of Trade, and as there is a prospect that it will pass into law during the present session, it may be useful to give an outline of its provisions.

The main responsibility for carrying out the provisions of the Bill is to be entrusted to an officer appointed by the Board of Trade, and called the "Comptroller-General of Patents, Designs and Trade Marks." The Bill deals in the first place with the law relating to patents. It provides that any person or persons may make application to the Comptroller for the grant of a patent in a form set forth in the Schedule, which must contain a declaration as to the invention for which a patent is sought, accompanied by at least a provisional specification; but if a complete specification is not furnished within nine months the application is to be deemed abandoned. This application is to be referred to an examiner, and upon his reporting in favour of the acceptance of the specification, the fact is to be advertised by the comptroller and the application and specification, with drawings, if any, are to be open to public inspection. Notice of objection may be lodged at any time within two months of the date of the advertisement, but in the event of there being no opposition the patent is then to be sealed and issued. During the whole period between the date of the application and the sealing of a patent provisional protection is to be given, but between the acceptance of the complete specification and the sealing of the patent the applicant will enjoy the same privileges as if the patent were already granted. Every patent is to be in force for the term of fourteen years, provided that the prescribed payments are made. These are £1 on application for provisional protection, £3 on filing a complete specification, £50 more on a certificate of renewal before the end of four years from the date of the patent and another £100 on a certificate of renewal before the end of seven years from date of payment. Fees in respect to other matters under this part of the Act are to be fixed by the Board of Trade with the sanction of the Treasury. It would, however, appear probable that in ordinary unopposed cases the patentee would have protection during nearly four years before he would be called upon to pay any very large sum of money. Another arrangement by which the payment of fees is spread over all the years up to the thirteenth seems to be still more favourable. Power is reserved to the Board of Trade, under certain conditions, to compel a patentee to grant licences on reasonable terms. Petitions for the extension of terms of patents are to be presented to the Queen in Council.

The next part of the Bill provides for the registration of designs, such registration to confer upon the registered proprietor of a design a copyright in it for a term of five years. The fees to be paid for this registration are to be fixed by the Board of Trade, with the sanction of the Treasury.

But the portion of the Bill which relates to the registration of trade-marks is probably that which will be of most interest to the readers of this Journal, since it proposes to repeal all the existing Acts upon the subject and replace them by provisions which vary to some extent as to the details. If the Bill passes in its present state all applications for the registration of trade marks will in future have to be made to the "Comptroller-General of Patents, Designs, and Trade Marks," on a prescribed form, which is to contain one representation of the trade mark sought to be registered and be accompanied by two other representations of it affixed to separate sheets of foolscap, and is to state the class in which registration is desired to be effected. Each application will also have to be accompanied by a statutory declaration to the effect that the trade mark in question is not, to the best of the applicant's knowledge and belief, in use by any other person for the goods in respect of which registration is sought, and stating how long it has been in use by the applicant. A trade mark will have to consist of or contain at least one of the following essential particulars: (*a*) a name of an individual or firm printed, impressed or woven in some particular and distinctive manner; or (*b*) a written signature or copy of a written signature of the individual or firm applying for registration thereof as a trade mark; or (*c*) a distinctive device, mark, brand, heading, label, ticket, or fancy words not in common use; and to any one or more of these particulars may be added any letters, words or figures, or combination of the same. But special and distinctive words, letters, figures, or combinations of them that were in use as trade marks before the 13th of August, 1875, are to be eligible for registration by themselves. The introduction of the words "or fancy words not in common use," would appear to be intended to provide for the registration of names as trade marks, which it has been decided could not be done under the existing Act. The word "brand" has also been introduced. Each trade mark will have to be registered for particular goods or classes of goods. In the case, however, of an application by one person to register several trade marks, resembling each other in the material particulars, but with variations indicating differences in quality, price, etc., it will be permissible to register them as a series in one registration, the sole drawback being that the series will only be transferable as a whole. The rules as to classification, fees, etc., existing at the time of the passing of the Act are to continue in force until formally modified by the Board of Trade, unless they are inconsistent with the provisions of the new law. The comptroller may, if he think fit, refuse to register a trade mark; the applicant will then be at liberty to appeal to the Board of Trade, who may refer the appeal for decision to the law courts. Otherwise, every application is to be advertised as soon as possible after its receipt, and within the next two months notice of opposition, in duplicate, may be given at the Patent Office. A copy of such notice if received is to be sent to the applicant, who will have to send in his counter statement within two months or be deemed to have abandoned his application. Should the opposition be continued, the case will be set down for trial upon the objector giving security for costs. Curiously enough there is no explicit provision in any part of the Bill for the registration of a trade mark at any particular stage, although of course this is implied.

Registration of a trade mark under this Act is to be deemed equivalent to the public use of it, and the registration of a person as first proprietor of a trade mark is to be *primâ facie* evidence, and after the expiration of five years from the date of registration is to be held conclusive evidence of his exclusive right to the use of it in connection with the class of goods for which it is registered. A book is to be kept at the Patent Office in which are to be entered the names and addresses of proprietors of registered trade marks and notifications of assignments and transmissions of them. At a time not less than two months or more than three months before the expiration of fourteen years from the date of registration, and of each successive fourteen years, the comptroller is to send a notice to the registered proprietor of a trade mark, notifying the date of the approaching expiration, and that unless a prescribed fee be paid before that time, the trade mark will be removed from the register. In the event of the fee not being paid within a month a second notice is to be sent, and should the fourteen years run out before payment is made, the comptroller will be empowered to remove the trade mark from the register. After removal, however, it may be restored within a limited time upon payment of an extra fee, and under any circumstances for a period of five years after removal it is to be deemed a trade mark already registered. The latter provisions are practically identical with the existing law on the subject. Authority will be given to the Company of Cutlers in Hallamshire to establish and keep, under certain supervision by the comptroller, a new register, to be called the "Sheffield Register," for cutlery and steel goods, and an arrangement is made for the closing of the present corporate register at the end of five years. It is worthy of note that no analogous provision is made giving authority for the registration of names or designs by the Stationers' Company. Certain provisions are also made in anticipation of any international arrangements as to patents that may be negotiated at a future time.

One offence under the Act will be the representation that an article is patented or that a trade mark is registered when it is not; and the representation will be deemed to have been made if the article or trade mark bear the word "patent," "patented," or "registered." Offenders are to be liable for every such offence, on summary conviction, to a fine not exceeding five pounds. Another offence is that to which attention was called at the last meeting of the Council by Dr. SYMES, which makes every person who, without due authority, assumes or uses in connection with any trade, business, calling or profession, the royal arms, or any arms so nearly resembling the same as to be calculated to deceive, liable on summary conviction to a fine not exceeding twenty pounds. Although this provision may be strictly in keeping with the spirit of the Bill the time is not ripe, in our opinion, for so stringent a restriction, and we doubt whether it would be found practicable to carry it into effect immediately even if passed. We have no particular sympathy with the custom of wearing borrowed plumes; but in respect to the use of the royal arms we cannot help thinking that the practice has now become so universal that it will require many months simply for the knowledge that it has been made illegal to permeate through all the classes that will be concerned. Almost all tradesmen, chemists and druggists not excepted, have long been in the habit of displaying the royal arms as an ornament on shop-fronts, goods, advertisements, invoices, labels, bags, carts, and in every conceivable way, and any attempt summarily to put a stop to the practice by the imposition of penalties will give rise to ill-feeling and inconvenience exceedingly disproportionate in importance to any useful object that can be thereby attained.

These are the principal provisions of the Bill, which, however, in one hundred and fourteen clauses contains a large number of details relating to certain contingencies that may arise. Subject to necessary modifications it is proposed that its operations shall extend also to Scotland, Ireland, the Isle of Man and the Channel Islands, and the time fixed for it to come into operation is the first day of next year.

THE INLAND PARCELS POST.

The Inland Parcels Post, which is to be commenced in this country on Wednesday next, promises to be so important an addition to public convenience, although not much in advance of what has been enjoyed on the Continent for many years past, that we have thought it desirable to publish *in extenso* in the present number the official regulations under which it is to be conducted. We hope that in doing so we shall not only be placing useful information before the readers of the Journal, but shall be also rendering some slight assistance to the Post Office authorities who, in perfecting the organization necessary for starting and carrying on satisfactorily what will probably prove to be an important augmentation of the already enormous business of the Department, have a task set before them that will try to the full the business capabilities with which they are so generally credited. The rules appear to be simple and easy to understand; the limits as to weight and measurement are distinct and present no difficulty. Evidently with proper care the parcels post will be available for the transmission of medicine. It will be seen that liquids and semi-liquids will not be accepted unless in bottles or cans securely stoppered, and that bottles or glass in any form must be so packed as to be secure from breakage; powders also will have o be so packed that they cannot escape during transmission. We notice that the Postmaster-General proposes to contract himself out of any liability to make good any claim in respect of lost or damaged parcels. We doubt, however, whether such a provision would stand good, for in undertaking the charge of goods for the purpose of transit it is implied that a reasonable amount of care will be exercised, which it might be assumed should, as a rule, be sufficient to prevent any of the parcels from going astray. It is important to observe that in order to bring parcels within the terms of the parcels post they must be taken into a post office and handed over the counter, and not posted in a letter box.

The second reading of the Medical Acts Amendment Bill was the ninth order of the day in the House of Commons, on Tuesday.

* * *

Notwithstanding the late period of the session and the great pressure of business in Parliament, a Petroleum Bill was introduced into the House of Lords by Earl Granville last week, and was set down for second reading on Thursday. As the object of the Bill is to consolidate and amend the whole of the existing law relating to petroleum, we propose to give an epitome of it next week.

* * *

The Thirty-Second Annual General Meeting of the General Austrian Pharmaceutical Association is to be held in Vienna, on Monday and Tuesday, the 20th and 21st of August. As the International Pharmaceutical Exhibition will be open in Vienna at the same time, as well as the Electric Exhibition, it is expected that the meeting will be unusually well attended.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

July 11, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council

MAJOR EXAMINATION.

Seven candidates were examined. *Three* failed. The undermentioned *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Bessell, James Walter............Ludlow.
Corder, Walter Shewell ....Sunderland.
Gulliver, Walter Frederick......London.
Hopkins, William Richard ......Aberystwith.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Eleven* failed. The undermentioned *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Acton, Samuel ....Liverpool.
Adams, Charles Mansley ......Bath.
Adamson, Joseph William ......Epworth.
Atkinson, Richard ....Penrith.
Badcock, Henry Southgate R....South Petherton.
Beale, William Scott ....London.
Beck, Nathan George ....Lyme Regis.
Brown, Joseph ....Walker-on-Tyne.
Burnett, Joseph Fearon ....Hyde.
Charge, Arthur William ....Chichester.
Haddock, James ....Bedford, Leigh.
Jones, David.........................Carnarvon.

July 12, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MAJOR EXAMINATION.

Eight candidates were examined. *One* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Baily, Edward ....Ramsgate.
Barnes, James Burden............Knightsbridge.
Crow, William Edward ....Louth.
Houfe, Robert William ....York.
Ivatt, Albert..........................Cottingham.
Johns, Henry Benj. Jeffery ...Southampton.
King, Arthur ....Norwich.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Eleven* failed. The undermentioned *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Beck, Percy Charles ....Norwich.
Crofts, John Ernest..............Leicester.
Crompton, William ....Bury.
Davies, Edward Charles James.London.
Denham, Albert Shaw............Preston.
Dewes, George ....Wolverhampton.
Dickie, John..........................Whitehaven.
Dickson, John ....Dumfries.
Edmunds, Henry Herbert ......Mere.
Reynolds, Richard Freshfield...Leeds.
Scupham, Herbert ....Ulceby.
Wilson, David Wm. Richd. ...Thirsk.

July 13, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

MINOR EXAMINATION.

Thirty candidates were examined. *Twenty-three* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Elliott, Stephen James ....Preston.
Hague, William ....Sheffield.
Hart, Frederick Charles ....Tongham.
Heath, Walter Edwin ....Coleshill.
Hordley, Henry Clement........Stoke-on-Trent.
Hudson, Alfred Wickens........London.
King, Frederick Herbert........Market Drayton.

July 18, 1883.

Present—Mr. Carteighe, President: Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

MAJOR EXAMINATION.

Six candidates were examined. *Three* failed. The undermentioned *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Corder, Edward ....Norwich.
Presbury, Herbert Henry ....London.
Ranken, Charles ....Sunderland.

MINOR EXAMINATION.

Twenty five candidates were examined. *Fifteen* failed. The undermentioned *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barnes, William Robert ....Plaistow.
Capper, Henry ....Liverpool.
Inger, George Edward........Nottingham.
Kay, Thomas Wilkinson........Manchester.
Keeling, Arthur Gadsby........Walthamstow.
Kelly, John George ....Leicester.
Lambert, Oliver ....Hull.
Lees, James ....Leighton Buzzard.
Metcalf, Rowland Alfred ....Uxbridge.
Sergeant, Furlow Ross ....Goxhill.

July 19, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Five* failed. The undermentioned *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Rees, David ....Newcastle Emlyn.
Williams, William Lloyd ....Buckley.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Seventeen* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Milton, William Edwin ....Chew Magna.
Mowatt, John Rodman ....London.
Munkman, Robert Allen ....Boston.
Palmer, Harvey ....Wingham.
Parker, Edmund Lloyd Philips..Nottingham.
Peck, Henry Frederick ....London.
Pottage, Edwin........Beverley.
Walker, George Edward........Royston.

July 20, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MINOR EXAMINATION.

Thirty candidates were examined. *Twenty-four* failed. The undermentioned *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Roberts, Edmund........Upper Norwood.
Rowland, Langshaw ....Wrexham.
Shepard, William........Newport, I. W.
Stafford, Robert ....Nottingham.
Weller, James Mills........Chichester.
Wiggin, John Chinery........Ipswich.

MODIFIED EXAMINATION.

One candidate was examined, but failed to pass.

PRELIMINARY EXAMINATION.

The undermentioned certificates were accepted in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Jones, Edward Owen ....Llangollen.
Leonard, Charles Edward ....Lewes.

Certificate of the Faculty of Physicians and Surgeons of Glasgow.

Baldwin, Aquila ....Birmingham.

Certificates of the University of Oxford.

Davis, Henry Baker ....Swansea.
Hulland, James ....Bath.

PRELIMINARY EXAMINATION.

The report of the College of Preceptors on the Preliminary examination, held on July 3, was received.

Four hundred and fifty-one candidates had presented themselves for examination, of whom *two hundred and twenty-five* had failed. The following *two hundred and twenty-six* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

Anderson, Frederick Ernest ...Thorne.
Andrews, Dormer Frederick ...Chatham.
Aspden, Edwin........Blackburn.
Atkinson, Joseph Andrew ....Spilsby.
Austin, James ....Birmingham.
Baker, Alfred Henry Sauzen...Gateshead.
Bambridge, Lewis Thomas........London.
Bamforth, Alan ....Slaithwaite.
Barclay, James Christian ....Aberdeen.
Barker, James Herbert Bond...Mold.
Bates, Frederick ....Allendale.
Batty, Thomas ....Southampton.
Bennett, Arthur ....Widnes.
Billing, George Alfred........Bodmin.
Billyard, William Frederick .. Boston.
Bird, Frederick William........Coventry.
Birkett, George........Morecambe.
Black, John Frank ....Aberdeen.
Black, Robert ....Aberdeen.
Bond, Ernest Greensill ....Liverpool.
Bonnett, Frederick ....Doncaster.
Boole, Lucy Everest ....London.
Boulton, Ernest Henry Charles.Market Rasen.
Bourne, Henry Fred ....Louth.
Bowen, Frederic Tamerlane ...Rye.
Bowron, Henry Edward........Liverpool.
Bradbrook, Walter Young........London.
Bradley, Nathaniel Lade........Margate.
Bray, John ....Lochmaben.
Brennan, James ....Pendleton.

Broomhead, James ....Aberdeen.
Buchan, George ....Peterhead.
Burgess, Arthur Leland ....Guernsey.
Camm, Charles Percy ....Wolverley.
Carter, Samuel ....Newlyn.
Chalmers, William ....Dundee.
Charles, Thomas Watkin.........Castletown.
Clarke, Charles Henry ....London.
Clifford, Raymond Alfred ......Evesham.
Clough, Joseph.....................Bramley.
Clowser, David William.........Winchester.
Cobham, George William ......Gravesend.
Connochie, James ....Selkirk.
Coombes, George John, Jun. ...Nottingham.
Cooper, Charles Henry ....Kettering.
Courtis, Terrell......................London.
Cousins, Alexander ....Weston-super-Mare.
Cowan, Joseph......................Annan.
Cowin, William Stephen.........Union Mills.
Cox, James Augustus ....Bath.
Cripps, Frank Alt..................Devizes.
Curtis, George ....Aberdeen.
Davidson, Joshua...................Lancaster.
Davy, Percy ....Rotherham.
Day, Charles Frederick ....Maidstone.
Dickie, Adam ....Glasgow.
Dickson, James Stewart.........Dumfries.
Drinkwater, Weston ....Patricroft.
Dudderidge, Frank Rawlinson..Blandford.
Dugan, Hugh Mathieson ......Aberdeen.
Duncan, John Glendinning B...Gainsborough.
Dwelly, Hedley Egbert ....Maidstone.
Edwards, Edward Price ....Mold.
Emberton, Frederick Charles...Silverdale.
Evans, Griffith ....Machynlleth.
Evans, Maurice ....Welshpool.
Evans, Rees ....Llanybyther.
Ewens, Francis Leonard.........Crewkerne.
Fechtner, Arthur Louis Wm....Hull.
Fleming, Howard ....Titchfield.
Forster, James ....Carlisle.
Fullerton, Robert...................Dumbarton.
Furness, Walter ....Accrington.
Gamble, Arthur George ....Yarmouth.
Gates, Colvin ....Moffat.
Gelston, Percival John Neill ...Derby.
George, David ....Cardigan.
Gibbs, Arthur ....Blackheath.
Gibson, Horton John ....Grantham.
Gilmour, James Parlane.........Burntisland.
Gilmour, John ....Burntisland.
Godber, James ....Alfreton.
Good, John Thomas................Barton-on-Humber.
Gordon, Robert ....Glasgow.
Grant, James ....Elgin.
Gregory, Bromly George.........Weymouth.
Greensit, John William ....Masham.
Grimshaw, Charles Roger ......Preston.
Guest, William Joseph ....Walsall.
Hanson, Arthur ....Queensbury.
Harbord, Richard Hutchinson...London.
Harden, Arthur George ....Ash-next-Sandwich.
Harries, Howell ....St. Clears.
Harris, George William ....Nottingham.
Haslam, George Thomas.........Skegness.
Haywood, William Henry ......Liverpool.
Heap, Arthur ....Coventry.
Hearnden, Frederick ....London.
Hemstead, William ....Tunbridge Wells.
Henstock, Thomas ....Hanley.
Herbert, Herbert.....................Bath.
Hetherington, John.................Moffat.
Hider, Francis ....London.
Hillman, Charles Edward ......Westbury.
Hilton, Albert ....Hurst.
Hobbs, Thomas Auther ....Worcester.
Hooper, Charles Reginald ......Dowlais.
Hordle, Arthur George ....Clevedon.
Horry, William Thomas ....Boston.
Hutchinson, James Sutcliffe ...Rochdale.
Ingram, George Thomas ....Louth.
Jacks, Frederick ....Longton.
Jeffcoat, Joseph George ....London.
Jenkins, William Thomas ......Kidwelly.
Johnson, John Richard ....Sheffield.
Johnston, George Henry.........Barnstaple.
Johnstone, John ....Selkirk.
Jones, David..........................Llandilo.
Jones, David Alban.................Aberayron.
Jones, Evan ....Bryngwran.
Jones, John Hughes ....Carmarthen.
Keyzor, Alfred Abraham ......London.
Kilpatrick, Robert ....Edinburgh.
Kirkby, John George ....Algarkirk.
Kirkup, George John ....Newcastle-on-Tyne.
Knapp, Edward Thomas..........London.
Lamont, William ....Forfar.
Lawrenson, John....................Radcliffe.
Lawson, Robert Murray ....Dumfries.
Lee, John George....................Alfreton.
Lewis, Phillip Reynolds ....Carmarthen.
Lewis, Thomas ....Wednesbury.
Lindsay, Robert Alex ....Montrose.
Lord, William Butler ....Lancaster.
Lothian, John ....Coldstream.
Lovatt, Harry Percy Perrin ...Wem.
McAllister, Robert D. S. ......Helensburgh.
McKenzie, James....................Cullen.
Macaulay, Robert Symington...Dumfries.
Macdonald, William ....Appin.
Macdougal, David Grierson ..Kilmarnock.
Mackie, Arthur Chadwick ......Blackpool.
Macqueen, Andrew Stewart ...Glasgow.
Maddock, Herbert ....Manchester.
Manson, William Mackenzie ...Edinburgh.
Marr, John Charles.................Hull.
Marshall, David Woolley ......Machynlleth.
Marshall, Lawton Parry.........Machynlleth.
Martin, William Morley.........Redruth.
Maxwell, John ....Kilmarnock.
Melvin, Andrew Gray.............Aberdeen.
Melrose, John ....Kelso.
Miller, William Gow ....Wick.
Mitchell, Patrick ....Kingussie.
Mitchell, Robert Harry ....Rutherglen.
Moore, Leopold Frank ....Leicester.
Morley, William John.............Jersey.
Murdoch, John Thomson ......Edinburgh.
Murray, John ....Crieff.
Neve, William Howard ....Prescot.
Northcott, John Squire ....Devonport.
Nosworthy, Allan Percy.........Yeovil.
Nunn, Arthur William ....Colchester.
Oatway, Sydney Richard ......Bideford.
Osborn, James Ernest.............Middlesborough.
Parkinson, Cecil Henry ....Louth.
Parry, John ....London.
Patchett, John ....Halifax.
Paterson, Henry ....Edinburgh.
Paton, George ....Dumfries.
Pearce, Seymour D..................London.
Plato, John Mason ....Hereford.
Price, Walter William ....Worcester.
Priddey, Henry Ernest ....London.
Prior, John ....Darlington.
Ralph, Frank Horatio.............Devonport.
Raper, Edward ....London.
Richards, Harry ....Blandford.
Richards, Richard Henry ......Ivybridge.
Riding, William John.............Ormskirk.
Riley, Thomas Herbert ....Chapel Allerton.
Rogers, Charles Henry ....Ipswich.

Rogers, Oswald.....................Northwich.
Robinson, William Albert ......Carlisle.
Sargent, Joseph Albert ....Louth.
Sawbridge, Ernest Edward......Foleshill.
Scarr, Stansfield ....Todmorden.
Shaw, John ....Bradford.
Simpson, James William ......Maidstone.
Smith, Field Evans ....Montrose.
Smith, James Duncan Audley...Edinburgh.
Smith, John ....Aberdeen.
Smith, William.........................Aberavon.
Spencer, John Christopher ......Manningham.
Squire, George ....Barnsley.
Stenhouse, Robert ....Dalkeith.
Stevenson, Robert ....Edinburgh.
Stewart, John Armstrong ......Dalkeith.
Stothert, Robert ....Blackburn.
Styles, Arthur .... Warwick.
Tatherly, Robert ....Newcastle-on-Tyne.
Teasdale, John.........................Bramley.
Tomkins, William ....Sheffield.
Towers, Wm. Londesborough...Barrow-on-Humber.
Turner, Harold Strange ....Winchester.
Walker, George Stewart.........Greenock.
Wallace, William John .... Plympton.
Warren, Thomas ....Hingham.
Watson, John ....Maxwelltown.
Watkinson, Edward Wade......Bradford.
Walter, John Albert ....Ampleforth.
Watts, John William ....Finchley.
Webber, Ernest Distin ....Tunbridge Wells.
Webster, John ....Buckie.
West, George William............Stokesley.
Whitfield, George... ....Scarborough.
Wilkerson, Albert Henry ....Epsom.
Wilkinson, William Arthur ...Colne.
Williams, George Whitfield ...Cardiff.
Williams, Richard ....Llangefni.
Willson, John Wherry ....Peterborough.
Wilson, Abel Ernest ....Stockport.
Wilson, Alexander George ....Elgin.
Wilson, Alexander W. ....Aberdeen.
Wilson, Arthur Edward ....Settle.
Wilson, John William............Harrogate.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates. Exam-ined.	Passed.	Failed.		Candidates. Exam-ined.	Passed.	Failed.
Aberdeen	16	13	3	Jersey	1	1	0
Birmingham	15	8	7	Lancaster	6	4	2
Brighton	7	1	6	Leeds	23	11	12
Bristol	9	5	4	Lincoln	13	9	4
Cambridge	4	1	3	Liverpool	21	9	12
Canterbury	5	3	2	London	63	26	37
Cardiff	12	4	8	Manchester	33	15	18
Carlisle	9	8	1	Newcastle-on-T.	7	4	3
Carmarthen	16	8	8	Northampton	3	1	2
Carnarvon	7	2	5	Norwich	9	2	7
Cheltenham	2	0	2	Nottingham	13	6	7
Darlington	6	3	3	Oxford	1	0	1
Douglas	3	1	2	Peterborough	4	3	1
Dundee	6	4	2	Sheffield	10	4	6
Edinburgh	29	16	13	Shrewsbury	11	7	4
Exeter	13	6	7	Southampton	10	8	2
Glasgow	22	11	11	Truro	7	4	3
Guernsey	3	1	2	Worcester	7	5	2
Hull	9	4	5	York	9	4	5
Inverness	7	4	3				

The questions set for examination were as follows —

Time allowed: Three hours for the three subjects.

I. LATIN.

1. Translate into English:—

(i.) Pro multitudine autem hominum, et pro gloria belli atque fortitudinis, angustos se fines *habere* arbitrabantur. (ii.) Caesar suos a proelio continebat, ac satis habebat in praesentia, hostem rapinis, pabulationibus, populationibusque *prohibere.* (iii.) Sese tamen et amore fraterno, et existimatione vulgi commoveri. (iv.) Hic locus ab hoste circiter passus sexcentos, uti dictum est, aberat. (v.) Quum hostium acies a sinistro cornu pulsa, atque in fugam conversa esset, a dextro cornu vehementer multitudine suorum nostram aciem premebant. Id quum *animadvertisset* Publius Crassus adolescens, qui equitatui praeerat, quod expeditior erat, quam ii, qui inter aciem versabantur, tertiam aciem laborantibus nostris subsidio *misit.*

2. Account for the moods of the verbs in italics, and give the principal parts of these verbs.

3. Decline in full—*hic locus, dextro cornu.*

4. Translate into Latin:—

(i.) Two days afterwards, Ariovistus sends ambassadors to Cæsar. (ii.) It seemed most convenient to send to him a son of Caius Valerius. (iii.) This was the kind of battle in which the Germans had exercised themselves. (iv.) A good citizen sides-with (*adsum*) his native country in the time of danger.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

1. A grocer buys a chest of tea containing 432 lbs. at 3*s.* 8½*d.* per lb. He sells 360 lbs. at 4*s.* 3¼*d.* per lb., and the remainder, which is injured, at half the cost price per lb. Find his gain.

2. Simplify $\dfrac{\frac{1}{2}+\frac{1}{3}+\frac{1}{4}}{\dfrac{1}{2\frac{1}{2}}+\dfrac{1}{3\frac{1}{2}}+\dfrac{1}{4\frac{1}{2}}}$

3. Find the value of ·6 of £1 + ·3125 of a shilling + $\cdot\dot{2}$ of a guinea.

4. If a pound of sugar cost ·0703125 of 16*s.*, what is the value of ·0625 cwt.?.

5. What sum of money will amount to £256 10*s.* in 4 years at 3½ per cent. simple interest?

III. ENGLISH.

1. Define *preposition.* What are the principal relations expressed by prepositions?

2. Give four of the rules of English syntax which you deem most important.

3. Parse fully—"What means this heaviness that hangs upon me?"

4. Write a short composition on *one* of the following subjects:—

(i.) The advantages derivable from a knowledge of Latin.
(ii.) The history of some medical or scientific discovery.
(iii.) Emigration.
(iv.) The cultivation of plants and flowers.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Thursday, July 19, at 4.30 p.m.

Present:—Professor Attfield, F.R.S., etc., President, in the chair; Messrs Carteighe, Ekin, Naylor, Southall, Taylor, and Dr. Thresh; Messrs. Benger and Plowman (Hon. Secs.) and Mr. Ashton (Local Secretary for Southport).

Letters of apology for non-attendance were read from Messrs. Groves, Kinninmont, Payne and Young.

Mr. Ashton (Southport) reported that the preparations of the Local Committee were nearly complete. The proprietor of the Prince of Wales Hotel had guaranteed forty beds for members of the Conference, and he was of opinion that more could be obtained if required. Arrangements had been made for a visit on the Thursday morning to the Plate Glass Company's Works and the Sutton Alkali Works at St. Helen's. On the Thursday afternoon there would be a Garden Party in the Botanical Gardens.

The Secretaries reported that, acting on instructions received at the last meeting of the Executive Committee, they had communicated with a number of gentlemen residing abroad with a view to the appointment of Colonial Local Secretaries in Canada, Cape Colony, India, New South Wales, New Zealand, Queensland, South Australia, Tasmania, Victoria, and the West Indies. A sufficient time had not yet elapsed for any replies to reach England.

They also reported that circulars had been issued to all registered chemists in Great Britain and Ireland not already members, inviting them to membership of the Conference. The number sent was 11,567, and the total cost would be approximately £91.

The following grants were made:—£5 to Messrs. Dunstan and Short to investigate the pharmaceutical preparations of nux vomica, principally in regard to their alkaloidal value; £10 to Messrs. Dunstan and Ransom to further extend the method of alkaloidal extraction with the chloroform-alcohol mixture; £2 2*s.* to Mr. W. Elborne to purchase material for determining the comparative pharmaceutical value of commercial rhubarb.

The place of meeting for 1884 was considered.

The Honorary Secretaries reported that reports and papers had been promised for the Southport meeting by Mr. A. H. Jackson, B.Sc., Dr. Quinlan, and Messrs. Barnes, Dunstan, Elborne, Greenish, Groves, Mason, Naylor, Stanford, Willmott and Woodland.

With regard to the Bell and Hills gift of books, Mr. Ashton said that no association of chemists existed at Southport, but he thought it probable that an arrangement could be made to place the books in the public library for the use of the pharmacists of the town, reserving the power to take them away at a future time, if an association should be formed. It was decided that the matter should be left in the hands of the President and Honorary Secretaries.

A letter of thanks for a copy of the Year-Book was read from the Pharmaceutical Society of Victoria.

The thanks of the Conference were accorded to the Pharmaceutical Society of Great Britain for the gift of a copy of the 'Register of Chemists and Druggists for 1883,' and to the Pharmaceutical Society of Ireland for two copies of the 'Calendar of the Pharmaceutical Society of Ireland for 1883.'

Parliamentary and Law Proceedings.

Action respecting the Use of a Title.—"Sweet Essence of Rennet."

Important Injunction Motion.

In the Chancery Division of the Court of Justice, Dublin, on Tuesday, July 17, an application was made on behalf of the plaintiffs, M'Master, Hodgson and Co., a firm of wholesale druggists and oil merchants in Capel Street, against the defendants, William Hayes and Co., who carry on business at 12, Grafton Street, as druggists, for an injunction restraining them from affixing on bottles or other vessels a label with the words "Warren's sweet essence of rennet for making curds and whey," or any other label, so as to be a colourable imitation of the label under which the plaintiffs sell that preparation.

Mr. Holmes, Q.C., in support of the application, relied on an affidavit by Mr. E. M. Hodgson, senior partner, stating that the sweet essence of rennet was a composition free from salt or mineral acid, and so more nutritious and easy of digestion than the ordinary rennet. When it was first manufactured by his firm John Vanston Warren was the clerk in charge of the perfumery and essence department, and his name was adopted as the trade label, viz., "Warren's sweet essence of rennet for making curds and whey." The firm were sole proprietors of the formula for the manufacture of the article, and Mr. Warren witnessed the signature of the firm to the certificate of registration of the label as a trade mark in 1870. The preparation became very popular, and the firm obtained a prize medal for it at the Dublin Exhibition of 1872. Dr. Cameron, city analyst, recommended it in his lectures, and it was recommended by the *Lancet*, the *British Medical Journal*, the *Medical Press*, the *Medical Times*, the *Dublin Journal of Medical Science* and other public journals. The defendants had adopted these certificates. In 1874 Mr. Warren left the employment of the firm, and entered into partnership successively with Mr. Burnside as Warren and Co., and on Mr. Burnside's retirement with Mr. Stokes, and sold the sweet essence of rennet as their manufacture. An action was commenced against Warren and Co., but the company was wound up before the proceedings came to an issue. In August last it came to the knowledge of the firm that the defendants were selling a preparation called "Warren's sweet essence of rennet;" and on cautioning them against doing so, Mr. William Hayes replied claiming the formula and label as assignee of Mr. Warren. It appeared that when Mr. Warren left the employment of the firm he took a book containing the secret of that and other preparations, and that that book was purchased by Mr. Hayes, as part of the goodwill of Warren and Co.'s business. Counsel submitted that a case had been made for an *ad interim* injunction

Mr. Jellett, Q.C., in opposing the application as most untenable, said Mr. Warren was the inventor of the essence, and on leaving the firm he took with him his books containing the recipes for it and other preparations. On March 18, 1875, finding that Messrs. M'Master, Hodgson and Co., were still manufacturing the preparation he cautioned them against doing so. They then registered a new label "Sweet essence of rennet," under which they continued to sell until 1882, when they re-registered the old label and instituted the present action. In the meantime Mr. Hayes had purchased Warren's rights and registered the label. When his right was challenged he alone asserted it and put the plaintiffs at arm's length. The motion was one that ought not to be granted on the eve of the long vacation.

The Master of the Rolls, in refusing the application with costs, observed that *primâ facie* Mr. Warren or his assignees could proceed against the plaintiffs for piracy if they continued to vend the preparation as "Warren's." The defendants' trade mark which had as a device a globe surmounted by a phœnix was different from the plaintiffs' which had a cow and calf; but the bottles were similar in shape. He could not understand why the plaintiffs, a very eminent and well known firm, had not the word "Hodgson" or "M'Master" instead of "Warren" applied to the essence, except on the intelligible hypothesis that Warren was its inventor.

Mr. Holmes said it was perfectly clear on the affidavits that Mr. Warren was not the inventor, but a former *employé*, Mr. Thomas Deegan.—*Dublin Evening Mail.*

Correspondence.

Battley's Liq. Cinchonæ.

Sir,—Mr. Mee, in his letter in your last week's issue, says, "Mr. Wells says we are really without an extract representing the constituents of bark. For the sake of raising the question, I deny it, I say that Mr. Battley's preparation does fully and completely represent the constituents of this valuable remedy." And he precedes this statement by the further one, "Assertion is not fitting for men of science; we must prove our results by specific gravity, by estimation of the alkoloids, by chemical tests, and above all by the microscopical slide."

Mr. Mee, however, hardly follows on his own lines for he gives no data with respect to the estimation of the alkaloids, etc., and his position after all is mainly grounded on mere assertion.

Some years ago (*vide* 'Pharmaceutical Conference Proceedings,' for 1878) I examined a sample of Battley's liquor and found that each fluid drachm, which the label stated was equal to one ounce of the finest bark, contained only 2·05 grains of total alkaloids.

As a bark containing only 0·46 per cent. of total alkaloids can hardly be said to be of the finest quality, one is forced to the conclusion that the bark operated on was either of very poor quality or that it was very far from being exhausted, or again that in the process of "pegging away at it with water, of steeping it, of boiling it again and again," the alkaloids were degraded and lost. If a bark of average quality be taken and the exhaustion by Battley's process, as Mr. Mee asserts, be complete, there ought to be at least four times the amount of alkaloid in the resulting liquor. I believe, with Mr. Mee, that Battley's liquor is an excellent one, but the question is whether by Battley's or any other process it is possible to exhaust bark and concentrate to the extent claimed. It is in no captious spirit that I venture to refer to Mr. Mee's communication and I sympathize with his desire to break a lance in Mr. Battley's favour. After all, these assertions and counter assertions are not very satisfactory, nor do they redound to the credit of pharmacists as a body and it would not be a bad thing if a commission of three or four pharmacists were appointed, by the Pharmaceutical Conference or some other body, to go into the whole question. Manifestly trade considerations come in which might be troublesome to deal with, but this difficulty need hardly be insuperable.

C. Ekin.

Sir,—I have carefully looked through the column occupied by Mr. Mee under this heading in last week's Journal, but have failed to find the "query," unless it be the one with which he concludes his communication.

There is, however, one very striking statement contained therein.

Mr. Mee states that one pound of "Battley's liquor" contains the kinates of one pound of bark. Battley on his label states that "one fluid drachm is equivalent to one ounce of the finest bark," or in other words that two fluid ounces are equal to a pound.

Surely Mr. Mee can find a more effectual method of lauding his favourite "patent" than by describing its strength as one-eighth of that stated on the label.

With regard to the deposit he will find that the "liquor" has by no means lost this distinctive character, nor was it confined to the Crimean era. I have a bottle now before me with quite a gram of this crystalline matter at the bottom.

I think if Mr. Mee will try the experiment on some assayed bark he will find that it will require something more than "pegging away with water" to leave "nothing but woody fibre and cellulose."

Perhaps he will withdraw his theorem and work out the problem instead.

J. O. Braithwaite.

Assistants in India.

Sir,—A letter appeared in the *Pharmaceutical Journal* of April 28, which I think likely to be misleading as to the propects of an assistant's life in this country. Allow me to describe the colour of the shield on my side. I came out seventeen years ago, and at first was as pleased and favourably impressed as your correspondent. In my third year the malarious fever incidental to the country found me out and did not leave me for twenty-one months, and when it did leave it left me a very different man to what it found me. A firm here has lost eight assistants in sixteen years, three from heat apoplexy, one from abcess of the liver, the remainder from cholera and other causes. I have been in a man's company one evening, and heard the next day that three hours after leaving me the previous night he had been attacked with cholera. I went to see him, attended to him, and in an hour or two after laid him out a corpse, almost black, and in another twelve hours I helped to lower him into his grave. I helped to bury three friends in two days out of one house. This is not by any means exceptional, and is only what anyone must experience during a long residence in India.

Now for the work. I am in sole charge of the dispensing part of a mixed business in the Mofussil, and up at six in the morning and in business till 7 p.m., with the thermometer at 90° to 94°, streaming with perspiration like a Turkish bath. It is no uncommon thing to be called up once or twice a night, and during a cholera epidemic five or six times.

There is no Pharmacy Act here, and free trade in physic is rampant, and any person can, without asking leave or licence, dub himself "Pharmaceutical Chemist," or his place of business "Medical Hall." Any code of professional ethics is unknown, and to speak of such would be of as much use as speaking of the Greek articles or integral calculus to them. We are all cutting one another's throats, and selling Mrs. Allen's Hair Restorer, and such like, at a less profit than a London chemist who buys in one street and sells in another. Besides this there is one common enemy we all have to fight against, and that is the natives, who open a "Medical Hall" in the native part of the town, and get a native compounder, dismissed from some regimental hospital for some fault or other, to do the dispensing, and I am sorry to add some of the *patriotic medical men* recommend them in preference to their fellow countrymen, under the impression that they are cheaper (a false impression). The fact is, we, the non-official Europeans, are looked upon as interlopers, and the medical men are all Government officials. There is also the native practitioner, who in some instances are part-owners of the native druggist's shop, and in others levy a black mail of from 12½ to 25 per cent. I fancy substitution is not an unknown art amongst them either; at all events, I know enough of them and their dirty ways, that if I were a physic taker instead of a physic maker nothing would induce me to take physic from a native druggist. Summing up, I have only regretted coming out but once, and that has been *ever since* my third year out.

A Chemist of Twenty-six Years Standing.

Essential Oil of Almonds.

Sir, — The recent painful trial, at Maidstone, of a clergyman for the manslaugter of a girl at West Malling, by the administration of essential oil of bitter almonds, suggests the propriety of an alteration in the law relative to the sale of that dangerous substance.

Probably neither physicians nor pharmacists would object to its sale being prohibited altogether; but whilst it is permitted to be sold, it would be a boon to chemists, a safeguard to the public, and a definite and indisputable proof in cases of poisoning, if it were placed on Part 1 of the Schedule of Poisons, instead of on Part 2, as now.

In common with every chemist I have spoken to on the subject, I never could understand why a substance which usually contains from four to six times more prussic acid than the dilute hydrocyanic acid of the Pharmacopœia should not be subject to the same law. Is not this an anomaly which ought no longer to exist?

Maidstone. Wm. Rogers.

Communications, Letters, etc., have been received from Messrs. Cook, Hickings, Christie, Turpin, Gaubert, Wood, Williams, Giles, Cymro, T. F. T.

NOTES ON CINCHONA BARK.

BY DAVID HOWARD.

A curious evidence of the singular scientific acumen shown by the late Mr. McIvor in working out his process for renewing cinchona bark is given by some of the samples of "renewed" *C. succirubra* bark which reach us from Ceylon.

As is well known, in Mr. McIvor's process, alternate strips of the bark were removed down to the cambium, and the tree wrapped round with moss. The bark then renews over the whole surface, the new bark consisting almost entirely of cellular tissue, the total alkaloid being increased, and the cinchonidine giving place to quinine.

The "renewed" bark to which I call attention, on the other hand, shows a totally different structure; there is a mere skin of cellular tissue, the remainder being remarkably fibrous.

The explanation is not far to seek, the shaving process recommended by M. Moens as a substitute for Mr. McIvor's process gives good results just in proportion as it imitates the latter process. If the cut is sufficiently deep to cause the effusion of new bark, if I may so call it, the result both in quantity and quality of the renewed bark closely resembles that yielded by the stripping process.

But if, as is often now the case, the shaving is merely superficial and carried all round the tree the result is entirely different; in this case there is little or no formation of cellular tissue to replace that removed, a fresh epidermis forms, but apparently the circulation is carried on in the remaining fibrous tissue, which in fact seems to be developed further. The alteration in the composition of the alkaloid which is so characteristic of the true renewal does not take place in this case; if there is any change it is rather in the direction of an increase of the cinchonidine instead of quinine.

The subject is not merely interesting from the light it throws upon McIvor's process, but is one of great commercial importance. Unless the shaving process is so carried on as to produce, at least in part, the beneficial results of the older process of renewal it will lead to grievous disappointment, for the trees seem to suffer more from the wrong treatment than from the right.

It is to be feared that in many cases the temptation to get a quick return from the plantation by over-frequent and unskilful shaving is risking not only the quality of the crop but the health of the trees. Some planters are even advocating a return to the barbarous system of coppicing; but it is difficult to believe that this will generally be the case, with the strong evidence before their eyes of the benefits to be obtained by the more scientific system of treatment.

I do not venture into the vexed questions of hybrids and species in red bark; but when I find that "red bark" can be obtained yielding up to 4 and 5 per cent. of quinine from natural bark, I am very sure that there is a great field for skill in the selection or cultivation of cinchonas. There is much to be learnt in these matters. In the last drug sales, some samples of bark marked "hybrid" gave 4 per cent. of quinine, while others, also "hybrid," gave only 1 per cent. of quinine.

It is evidently no easy matter to distinguish by the eye the different varieties of trees which produce red bark of widely different quality. Some time ago I analysed a number of samples of bark from individual trees, sent me by J. A. Campbell, Esq., from Ceylon. They were renewed bark from trees giving red bark of very fine quality; the plants were all from the same nurseries, and were supposed to be of identical quality.

I found, however, that they varied very widely in the richness of the bark, as will be seen from the following table :—

	Quinine.	Cinchonidine.	Cinchonine.	Quinidine.
No. 1 . . .	6·2	0·3	0·3	0·1
" 2 . . .	2·6	0·6	trace	0·4
" 3 . . .	2·0	1·6	1·2	0·2
" 4 . . .	4·0	0·2	0·2	0·1
" 5 . . .	4·0	0·2	0·7	0·7
" 6 . . .	2·3	0·5	1·2	0·8
" 7 . . .	2·3	0·9	1·7	0·0
" 8 . . .	2·8	0·3	1·3	0·1
" 9 . . .	4·1	0·1	0·2	0·1
" 10 . . .	3·9	0·1	0·2	0·2

Mr. Campbell tells me that "notwithstanding the extraordinary difference in the analysis there is little difference to be seen between the most of the trees. Some are pubescent, however, and some are glabrous; some have rounder leaves than others and in some the flower is white, except in the centre of the corolla tube which is pink. Others, again, have pink flowers. Nos. 1, 2, 4, 9 and 10 are what we used to call hybrids; of these 4, 9 and 10 are much like officinalis in leaf and bark. No. 2 is subpubescent in leaf and only a moderate grower, the leaf being rounder than 4, 9 and 10, and lighter in colour. No. 1 is exactly what we would imagine, from Mr. Cross and Colonel Beddome's description, to be a true Pâta de Gallinazo. Leaf glabrous shiny on upper surface, soft, flat, and pointed at end; a fine grower considering the soil it is in." It is evident, therefore, that no general description will suffice to guide a planter in selecting the best sorts, but that the subject requires a minute study of individual trees of which the bark has been analysed.

Calisaya bark shows equal variations between different trees. I have found individual trees growing together in Ceylon to vary from 3·1 per cent. to 9·2 per cent. of quinine, and individual trees similarly growing together in the Wynaad to vary from 7·6 per cent. to 0·7 per cent. of quinine.

These variations can hardly be attributed to soil; the red barks were all growing in similar soil and under similar circumstances, and the Ceylon calisayas were also apparently growing under similar conditions.

No doubt soil does influence the richness of the bark to a very great extent; samples of bark from trees grown on poor soils, as far as my experience goes, always test below similar barks on rich soils. The richest bark, both succirubra and calisaya, that I have tested from Ceylon has been from land richly manured for coffee.

I think I have given instances enough to show how great are the possibilities of advantage in selection of the richest varieties of bark, while the study of soils, and the best mode of manuring and of preserving the bark, offer a wide field for profit to the intelligent planter. It is evident that if an 8 per cent. bark can be obtained from a tree giving an equal crop to those yielding 1 per cent. bark the increased value of the crop must be out of all proportion to the extra care in selection. Whether planters will have to adopt grafting or propagation by layers or cuttings, or whether it will prove practicable to obtain certain results from selection of seed or plants, is a matter of experience. Everything points to a great over-production of inferior bark, but there is little fear of the better qualities bringing remunerative prices if wisely cultivated.

SYRUP OF IODIDE OF IRON.

BY PERCY WELLS.

Many months ago I tried the effect of glycerine on a concentrated solution of protoiodide of iron, and had reason to be satisfied with the result, but when I mixed the compound with syrup the old difficulties met me. To overcome these was my object, and I think I have accomplished it. My process is briefly this:—I put ½ troy ounce of resublimed iodine into a N. M. flask with 80 grs. of iron wire or filings and f ℥vi of distilled water. After the action has ceased and the pale green solution is formed I add f ℥j of glycerine and heat the mixture to about 212°. It is now filtered *on to* 3 fluid ounces of cold viscid pale glucose syrup, put into a 10 ounce measure and then thoroughly mixed with a spatula, and if the product is less than 5 fluid ounces it is made up to that quantity by washing the filter with distilled water. The product will be slightly turbid for an hour or so, but afterwards becomes perfectly bright and of a very pale green colour and unaffected by time or temperature.

The value of the mixture of glycerine and glucose will some day be recognized, and I believe eventually it is destined to supersede sugar in pharmacy.

I recently sent to the Journal a formula for unalterable syrup of squills made with glycerine and glucose, and I hope the Pharmacopœia Revision Committee will make experiments so as to exclude cane sugar in the manufacture of syrups and substitute the articles I have named.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from p.* 24.)

Acidum Hydrobromicum Dilutum, U.S.P. (new).—Sp. gr. 1·077, contains 10 per cent. of HBr. "A clear, colourless liquid, odourless, having a strongly acid taste and an acid reaction. By heat it is completely volatilized." No process is given; but the characters evidently exclude the rough and ready methods of Wade and Fothergill. The tests given are the liberation of bromine by chlorine or nitric acid, the formation of a white precipitate of silver bromide when solution of silver nitrate is added, and for the absence of sulphuric acid. This acid has not been included in the new German Pharmacopœia.

Acidum Hydrochloricum, U.S.P., P.G.—In the U.S.P. the name "muriatic acid" has been given up, but the acid remains the same sp. gr. (1·160) as that in the B.P., though it is said to contain 31·9 per cent. of HCl, instead of 31·8. The P.G. "acidum hydrochloricum" is weaker, having a sp. gr. of 1·124 and containing only 25 per cent. of HCl.

Acidum Hydrochloricum Crudum, P.G.—A clear or opalescent more or less yellow liquid, fuming in air, sp. gr. not less than 1·158, and containing no less than 29 per cent. of HCl. The impurities permitted by the P.G., 1872, were traces of sulphuric and sulphurous acids, alumina and iron; but it was to be rejected if contaminated with arsenious acid as indicated by becoming brown through liberation of metallic arsenic after being heated with stannous chloride. Nothing is now said as to limit of impurities. The crude acid is used in Germany in the preparation of baths.

Acidum Hydrochloricum Dilutum. U.S.P., P.G.—The U.S.P. dilute acid, which is stronger than that in the U.S.P. of 1870 (sp. gr. 1·038), and slightly weaker than that in the B.P., is made by mixing 6 parts of hydrochloric acid and 13 of water; its sp. gr. is 1·049 and it contains 10 per cent. of HCl. The P.G. dilute acid is made by mixing equal parts by weight of hydrochloric acid and water; its sp. gr. is 1·061, and it contains 12·5 per cent. of HCl. The increase in strength of the U.S.P. dilute hydrochloric acid to 10 per cent. appears to be a decided improvement. In the Danish Pharmacopœia this strength had previously been adopted, and but little alteration would be required to bring those of the B.P. (10·58 per cent.) and the Dutch Pharmacopœia (10·50 per cent.) to the same standard. In the Austrian Pharmacopœia, on the other hand, it is close to that of the P.G., viz., 12·4 per cent.

Acidum Hydrocyanicum Dilutum, U.S.P.—Contains 2 per cent. of HCN. Two processes are given: one resembling that of the B.P., but in which the distillate from 20 parts of ferrocyanide is collected in 60 parts of dilute alcohol, and diluted to proper strength with distilled water; the other consists in decomposing 6 parts of cyanide of silver by a mixture of 5 parts of hydrochloric acid and 55 of water and decanting. The U.S.P. official method of assaying the strength of the solution in HCN, based upon Pappenheim's process (*Archiv*, 1878, 408), and the error vitiating it, have recently formed the subject of a paper by Cripps (*Pharm. Journ.*, [3], xiii., 917). A simple solution of hydrocyanic acid has not yet been included in the P.G., and the aqua lauro-cerasi has now been omitted; when this latter preparation is ordered aqua amygdalarum amararum, containing 0·01 per cent. of HCN is to be dispensed.

Acidum Lacticum, U.S.P., P.G.—In the U.S.P. this acid is described as a nearly colourless, syrupy liquid, sp. gr. 1·212, containing 75 per cent. of $HC_3H_5O_3$, odourless and having a very acid taste and acid reaction, freely miscible with water, alcohol and ether, but nearly insoluble in chloroform; not vaporized by a heat below 320° F. Tests are added to prove the absence of hydrochloric, sulphuric and sarcolactic acids, lead, iron, sugar, glycerin and organic impurities. In the P.G. the percentage strength is not indicated, but the sp. gr. has been decreased from 1·24 to 1·21–1·22, or equal to at least 10 per cent. Treatment with an equal volume of strong sulphuric acid is given in both works as a test for the presence of organic impurities (sugar, etc.); but whilst the U.S.P. implies that the mixture should be kept cold and allows a pale yellow colour the P.G. merely says that the mixture should remain colourless. The U.S.P. sp. gr., (1·212) is said to represent 75 per cent. of $HC_3H_5O_3$, but according to Hager (*Commentar*, p. 134) it would be 80 per cent.

Acidum Nitricum, U.S.P., P.G.—The acid described in the U.S.P. remains practically the same as the nitric acid, B.P., sp. gr. 1·420 and containing 69·4 per cent. of HNO_3; but tests have been added for the absence of arsenic acid, free iodine and hydriodic acid, the latter probably in consequence of the more extended use of Chili saltpetre in the manufacture of nitric acid. The P.G. acid under this name is much weaker, being of sp. gr. 1·185, and containing only 30 per cent. of acid. The P.G. also gives a test for the absence of hydriodic acid.

Acidum Nitricum Dilutum, U.S.P.—This has been reduced in strength in order to bring it into the category of 10 per cent. dilute acids. Its sp. gr. is 1·059; it is, therefore, considerably weaker than the B.P. "dilute" acid, which contains 17·44 per cent. A dilute acid (sp. gr. 1·086 to 1·089) has now been omitted from the P.G. Of the other European pharmacopœias, the Austrian has a dilute nitric acid containing 21·42 per cent. of HNO_3; the Russian and Swiss order 15 per cent. and the Dutch 17 to 17·5 per cent.

Acidum Nitricum Fumans, P.G.—This has been substituted in the P.G. for "acidum nitricum crudum," sp. gr. 1·323 to 1·331. It is described as a clear red-brown liquid, sp. gr. 1·45 to 1·50, giving off yellow-red suffocating vapour. Diluted with 150 parts of water, it must not be rendered turbid in five minutes by barium nitrate or silver nitrate. Notwithstanding this requirement the principal medicinal use of this acid in Germany is as a caustic.

Acidum Nitrohydrochloricum, U.S.P.—Nitric acid, 4; hydrochloric acid, 15. The relative proportion of hydrochloric acid in this and the dilute form is much larger than in U.S.P., 1870, where in the dilute acid it was then larger than in the B.P. Sp. gr. not given. There was an acidum chloronitrosum in the P.G., 1872, which was "non nisi ad dispensationem paretur," but this acid has now been omitted.

Acidum Nitrohydrochloricum Dilutum, U.S.P.—Nitric acid, 4; hydrochloric acid, 15; water, 76. The water to be added when effervescence has ceased.

Acidum Oleicum, U.S.P. (new).—The increasing use of the oleates has been recognized by the introduction of "oleic acid" into the U.S.P., but it is not in the P.G. It is described as: "A yellowish, oily liquid, gradually becoming brown, rancid and acid when exposed to the air; odourless or nearly so, tasteless, and when pure of a neutral reaction. Sp. gr. 0·800 to 0·810." Insoluble in water, completely soluble in alcohol, chloroform, benzol, benzin, oil of turpentine and fixed oils. Semisolid at 59·2° F., and when cooled to 39·2° it becomes a whitish mass of crystals. It should be completely saponified by potassium carbonate at a gentle heat, and the soap dissolved in water and exactly neutralized with acetic acid should give a precipitate with solution of acetate of lead which after twice washing in boiling water is almost entirely soluble in ether (absence of more than traces of palmitic and stearic acids). Equal volumes of the acid and alcohol, at 77° F., should give a clear solution, without separation of oil drops.

Acidum Phosphoricum, U.S.P. (new); P.G.—From the U.S.P. "glacial phosphoric acid" is now omitted, and its place is taken by an acid of sp. gr. 1·347, containing 50 per cent. of H_3PO_4. A recommendation of the Committee in favour of a stronger acid, sp. gr. 1·700, was not adopted. A process is given similar to that of the B.P. The finished product is specially directed to be tested for nitric, phosphorous and arsenic acids. If it be found to contain nitric acid, it is to be heated until the reaction disappears and then re-made up with water to 100 parts. If phosphorous acid be present, a mixture of 6 parts of nitric acid and 6 parts of water is added, the product evaporated until it no longer gives a reaction for phosphorous or nitric acids, and then again brought up to 100 parts with water. If arsenic acid be present this is to be removed by means of sulphuretted hydrogen, after diluting the product with 150 parts of water. The "acidum phosphoricum," P.G., for which no process is given, is of sp. gr. 1·120, and contains 20 per cent. of H_3PO_4.

Acidum Phosphoricum Dilutum, U.S.P.—Phosphoric acid, sp. gr. 1·347, 20; water, 80. It has a sp. gr. 1·057, and contains 10 per cent. of H_3PO_4. In the U.S.P., 1873, the sp. gr. was 1·056, and, besides the process of preparing it direct from phosphorus, there was an alternative one of preparing it from glacial phosphoric acid.

Acidum Pyrogallicum, P.G. (new).—Pyrogallol, or pyrogallic acid, which is a product of the action of heat on gallic acid, though largely used in photography, is not much used in medicine. It is reputed to have anti-fermentative and anti-putrefactive properties and has been recommended for the external treatment of psoriasis and other skin diseases, but the danger arising from its poisonous properties would appear to be a great drawback to its use. According to Hager a prescription ordering more than 0·25 gram in a single dose, or 1 gram in the day, ought not to be dispensed without special authorization. An alcoholic solution of pyrogallic acid is sometimes used as a brown hair dye.

Acidum Salicylicum, U.S.P. (new); P.G. (new). —In the U.S.P. the characters given for this acid are "Fine, light, white, prismatic, needle-shaped crystals, permanent in the air, free from odour of carbolic acid, but sometimes having an aromatic odour, of a sweetish and slightly acrid taste and an acid reaction." Solubilities: in water at 59° F., 1 in 450; in alcohol, 1 in 2½; in absolute alcohol and in ether, 1 in 2; in amylic alcohol, 1 in 3½; in chloroform, 1 in 80; in boiling water, 1 in 14; very soluble in boiling alcohol. Heated to about 347° F. (175° C.) the crystals melt, and at about 392° they sublime; at a higher temperature they are decomposed. The tests given are for hydrochloric acid, iron, carbolic acid and organic impurities. The test given for the presence of carbolic acid is that when 5 c.c. of an aqueous saturated solution is poured into a test-tube containing a crystal of potassium chlorate and 2 c.c. of hydrochloric acid, and solution of ammonia carefully poured on the top, the latter should assume a reddish or brownish tint.

It is interesting to note that in some respects these characters differ from those given for salicylic acid in the new German Pharmacopœia, into which it has also been introduced. The German work does not restrict the official acid to "fine" crystals, although according to Mr. Williams (*Pharm. Journ.*, [3], viii., 785), that form of crystallization is a distinctive mark of the pure natural acid; but it says:—"Crystalla levia, alba, aucubus similia vel *pulvis laxus, albus, crystallinus.*" Then the melting point is given as 15° C. lower, whilst with respect to the solubility in cold water there seems to be great diversity of opinion. The United States Committee had under its notice a statement of the German Committee, made in a preliminary report, similar to what has frequently appeared elsewhere, that salicylic acid is soluble in 300 parts of cold water; it preferred, however, to adopt 1 in 450. But the new German Pharmacopœia now says, "in aquæ frigidæ partibus quingentis triginta octo solvuntur;" whilst, as if to increase the confusion, in an appendix in the same work, giving the solubilities of chemicals in "numeris rotundatis," the solubility is given as 1 in 600. As it may be assumed that salicylic acid will be included in the forthcoming edition of the British Pharmacopœia it is to be hoped that these apparent discrepancies will soon be cleared up.

Acidum Sulphuricum, U.S.P., P.G.—In the U.S.P. the strength of this acid has been decreased from "sp. gr. 1·843" to "sp. gr. not below 1·840;" it contains not less than 96 per cent. of H_2SO_4. Tests are now given for freedom from lead, arsenic, copper, iron, and nitric, hydrochloric and sulphurous acids. In the P.G. also the character has been altered from "sp. gr. 1·840, answering to 98·5 per cent. of H_2SO_4" to "sp. gr. 1·836 to 1·840, containing in 100 parts 94 to 97 parts of H_2SO_4."

Acidum Sulphuricum Aromaticum, U.S.P.—Tincture of ginger and oil of cinnamon have been substituted in the formula for the corresponding powders. The preparation is of sp. gr. 0·955, and contains about 20 per cent. of official sulphuric acid. It is therefore nearly 7 per cent. stronger in acid than the B.P. preparation. Under the name of "*Mixtura sulfurica acida*," the P.G. has a simple solution of sulphuric acid in alcohol, without aromatics, sp. gr. 0·993 to 0·997, containing 25 per cent. of acid.

Acidum Sulphuricum Crudum is still retained in the P.G. It is an oil of vitriol of sp. gr. not less than 1·830, and containing not less than 91 per cent. of H_2SO_4. An "*Acidum sulfuricum fumans*" has been omitted.

Acidum Sulphuricum Dilutum.—The formula for the U.S.P. dilute acid is, sulphuric acid 1; water, 9. Its sp. gr. is 1·067 nearly, and it contains 10 per cent. of official sulphuric acid. It is therefore weaker than in U.S.P., 1870, or the B.P. The P.G. dilute sulphuric acid is the strongest of the four, having a sp. gr. of 1·11 to 1·114, which would correspond to about 16 per cent. of H_2SO_4.

Acidum Sulphurosum.—In the U.S.P. the trength of this aqueous solution has been considerably reduced; the sp. gr. of the 1870 preparation was 1·035, corresponding to 6·4 per cent. of SO_2, whilst that now ordered has a sp. gr. 1·022 to 1·023 and contains about 3·5 per cent. of SO_2. Several years ago (*Pharm. Journ.*, [2], x., 516) Mr. Umney called attention to the practical difficulties attending the preparation by the charcoal process of an aqueous solution of sulphurous acid containing more than about 5 or 6 per cent. of SO_2, and suggested that a solution of 1·027 sp. gr., containing 5 per cent. by weight of SO_2, should be substituted for the B.P. official preparation, which should contain 9·2 per cent. But the compilers of the U.S.P. have thought it convenient to go below even that standard. No attempt appears to have yet been made to introduce a solution in alcohol, which is said to be capable of taking up 300 times its bulk of sulphurous acid gas (*Pharm. Journ.*, [3], i., 465).

Acidum Tannicum, U.S.P., P.G.—The process has been omitted from the U.S.P. where the acid is described as in "light yellowish scales, permanent in the air, having a faint, peculiar odour, a strongly astringent taste and an acid reaction." Solubilities: in water at 59°, 1 in 6; in alcohol, 1 in 0·6; very soluble in boiling water and boiling alcohol; in glycerin, 1 in 6; sparingly soluble in absolute alcohol, freely in dilute alcohol, moderately in washed ether, and almost insoluble in absolute ether, chloroform, benzol and benzin. The P.G. describes tannic acid as "pulvis albus vel subflavus vel massa laxa, nitida, coloris pæne expers."

Acidum Tartaricum, U.S.P., P.G.—In the U.S.P. the solubilities given are—in water at 59°, 1 in 0·7; in alcohol, 1 in 2·5; in absolute alcohol, 1 in 36; in boiling water, 1 in 0·5; in boiling alcohol, 1 in 0·2; in ether, 1 in 23; in absolute ether, 1 in 250; nearly insoluble in chloroform, benzol and benzin.

Acidum Valerianicum has been wisely dismissed from both the U.S.P. and the P.G.

The following is a list of the acids included in the U.S.P. for 1870 and 1880, the P.G. for 1872 and 1882, and the B.P. for 1867, showing the representative percentage strengths so far as they are indicated. The sign o signifies that the acid is absent from the Pharmacopœia under which the sign is placed.

(*To be continued.*)

COMPARATIVE LIST OF POPULAR AND SCIENTIFIC NAMES OF THE ECONOMIC PLANTS OF BRAZIL.*

BY DR. T. PECKOLT.

Popular Name.	Systematic Name.
Abacateiro	Persea gratissima, Gaertn.
Abacaxi	*vide* Ananaz.
Abiu	Lucuma Caimito, Röm. et Sch.
Abobreira	Cúcurbita maxima, Duch.
Abobreira jerimú	Cucurbita Melopepo, L.
Abricoteiro	Mammea americana, L.
Abricoteiro de Brasil	Mimusops coriacea, Mart.
Abutua	Botryopsis platyphylla, Miers.
Acafrao da India	Crocus sativus, L.
Acelga	Beta Cicla, L.
Afiou	Arracacha esculenta, D.C.
Agoniada	Plumieria lancifolia, Müll.
Agriao	Sisymbrium pumilum, St. Hil.
Agriao da horta	Nasturtium officinale, R. Br.
Aipim	*vide* Mandioca.
Aipo	Apium graveolens, L.
Alcachofra	Cynara Scolymus, L.
Alface	Lactuca sativa, L.
Algarrobeira	Prosopis dulcis, H. B. K.
Algodoeiro	Gossypium vitifolium, Lam.
Alho	Allium sativum, L.
Alho grosso	Allium Scorodoprasum, L.
Alho porró	Allium Porrum, L.
Almacegueirà	Amyris ambrosiaca, Vellos.
Ambauba mansa	Pourouma cecropiæfolia, Mart.
Ameixeira de Canada	Eriobotrya japonica, Lindl.
Ameixeira da India	Eriobotrya japonica, Lindl.
Ameixeira preta	Prunus paranaense.
Ameixeira da terra	Ximenia americana, L.
Amendoim	Arachis hypogæa, L.
Amoreira	Morus nigra, L.
Amoreira da silva	Rubus brasiliensis, Mart.
Ananaz	Ananassa sativa, Lindl.
Anda-assú	Anda Gomesii, Juss.
Anil	Indigofera Anil, L.
Aniz estrellado	Illicium anisatum, L.
Araçazeiro	Psidium Araça, Radd.
Araçazeiro pera	Psidium variabile, Bg.
Arariba	Nossolia robusta, Vell.
Araríbá	Arariba rubra, Mart.
Ararixá (Rio)	Sterculia Chicha, St. Hil.
Arapoca	Raputia alba, Nees.
Araticum	Rollinia exalbida, Mart.
Araticum-Assú	Anona dioica, St. Hil.
Araticum mangue	Anona rhizantha, Eichl.
Arco de pipa	Erythroxylon utilissimum, Fr. All.
Aroeira	Schinus terebinthifolius, Radd.
Aroeira vajado	Schinus antiarthriticus, Mart.
Arroz	Oryza sativa, Linn.
Arruda do mato	Xanthoxylum Peckoltianum, ~~Eichl.~~ Engl.
Arvore do longa vida	Graphyria.

BLEACHING SPONGES.*

Several correspondents of the *Pharmaceutische Zeitung* communicate methods for bleaching sponges, all of which we have been acquainted with ourselves, and which we can recommend as quite satisfactory.

1. First clean, wash, and squeeze out the sponges; then dip them into a two per cent. solution of permanganate of potassium. Here they become quite brown (from separated manganic oxide); after ten minutes they are taken out, washed in water, again well pressed, and then dipped into a two per cent. solution of oxalic acid [we prefer diluted sulphuric (1 : 20) or diluted hydrochloric acid (1 : 15)], in which they become perfectly white. Success mainly depends on the soaking in the permanganate solution; if they are macerated too short a time, they do not become thoroughly white; if too long, they are apt to become rotten (Dr. Siemens).

2. First clean the sponges by immersing them in diluted hydrochloric acid. Then soak them in the bleaching liquid, composed of hyposulphite of sodium, one part, water, twelve parts, and hydrochloric acid, two parts. After some time, they are removed and well washed. To the last wash water a little glycerin is added in order to preserve the sponges soft. The liquid is best pressed out by passing the sponges through a clothes-wringer.

3. Toilet sponges, which have been in use, often become peculiarly slimy, fatty, and almost useless, owing to some action of the soap. Mere washing in distilled water does not remove the dificulty. It may be overcome by using fused chloride of calcium. The sponge is pressed as much as possible, placed on a plate, the powdered chloride of calcium sprinkled upon it, and allowed to deliquesce upon the sponge. After about half an hour, the sponge may be washed in water and dried, when it will become white (M. v. Valta).

Though all the above processes furnish satisfatory results, yet the following combination and modification of two of the above processes, which was devised by Mr. John Borham, and has been in use in Bellevue Hospital for a considerable time, will be found to work better still :—

Soak the sponges, previously deprived of sand and dirt by beating and washing, in a one per cent. solution of permanganate of potassium. Then remove them, wash them thoroughly with water, and press out the water. Next put them into a solution of one half pound of hyposulphite of sodium in one gallon of water, to which one ounce of oxalic acid has been added, and leave them in the solution for fifteen minutes. Finally, take them out, and wash them thoroughly.

By this treatment, the sponges are rendered perfectly white. Many sponges contain a more or less dark-coloured, brownish core. If treated only with permanganate and acid, the core is either not bleached at all, or if it has been somewhat bleached, the tint is apt to grow again darker. By the above modification, every portion of the sponge is rendered white, and remains so.

STATE AID FOR SCIENCE TEACHING.

THIRTY years have now elapsed since in a speech from the throne, upon the occasion of the opening of a session of Parliament, Her Majesty announced that a scheme had been prepared for adding a Science division to the Department of Practical Art, which had been established in the previous year. This scheme provided for an extension of a system of encouragement to local institutions for teaching practical science similar to that already commenced for schools for practical art, by the "creation in the metropolis of a science school of "the highest class, capable of affording the best "instruction and the most perfect training," and by aiding in the establishment of local science schools, such institutions to be made as largely self-supporting as possible. The praiseworthy ambition thus manifested for bringing Great Britain abreast of the continental nations most favoured in respect to scientific teaching has not been without result. It has no doubt extended and fostered a desire for scientific studies and been an immense boon to many who would not otherwise have been able to pursue them under such favourable conditions, and it has furnished opportunities to a much larger number of persons for acquiring a smattering of the sciences, which has at least the advantage of being better than no knowledge at all; on the other hand it has notoriously developed the art of preparing for examination, and it has made a considerable impression upon the national expenditure. To what extent the good effected preponderates over the disadvantages in the results, and whether the country derives the maximum possible of the former with the minimum of the latter are questions about which there has existed some diversity of opinion, especially in respect to the metropolitan "science school of the highest class," and this diversity of opinion has led to more than one reorganization before that institution took its present conglomerate form as the "Normal School of Science and Royal School of Mines." Some materials for assisting in the formation of a correct judgment are, however, furnished in the annual reports presented to Parliament by the Science and Art Department of the Privy Council, the thirtieth of which has just appeared.

The Report states that in the year 1882 the number of persons receiving elementary scientific instruction in 1402 schools having relations with the Department was 68,581, who were taught in 4881 separate classes, being an increase of 7404 pupils and 42 schools as compared with the previous year. The number of students who went up for examination from these schools was 43,331, and in addition there were 7290 candidates who presented themselves either as self-taught or from classes not entitled to claim payments on results, making a total of 50,621. Many of these persons presented themselves for examination in more than one subject, the number of papers worked being 76,063, of which 50,741 were passed, rather more than one-fourth of those accepted being ranked as "first class" in the respective stages. The "payments on results" made by the Department on account of the instruction that stands the test of examination are £2 for a "first class" and £1 for a "second class" in the elementary and in the advanced stages, and £2 for a "second" and £4 for a "first class" in "honours." Extra payments are made for attendance in organized "science schools," and special payments are made for practical chemistry and practical metallurgy. The total amount paid on account of the results of the examinations in 1882 was £45,376, or an average of 13*s.* 3*d.* per student. Payments were made to 1851 teachers, and the average payment per teacher was £24 10*s.* 3*d.*

So far as statistics are concerned therefore, the figures in the Report may be accepted as indicating that a slight break which occurred in 1881 in the steady but decided increase in the number of persons who annually prove capable of furnishing such evidence as the Department requires that they have been educated in certain sciences was not a commencement of a decline. When we turn, however, to the evidence as to the quality of the education, the statements in the Report are not so satisfactory. Apart from the disadvantage inseparable from any system of payment by results, in the temptation that it presents to teachers to neglect the systematic teaching of fundamental principles in favour of a preparation to meet certain anticipated, and to some extent inevitable, questions, the safeguards for ensuring proper qualifications in the teachers appear to be at present decidedly insufficient. This is not to be wondered at when it is remembered that during the last six years any person who has passed in the advanced stage of a science at an ordinary general examination in May has been deemed qualified to act as a teacher and earn payment on results, although this standard is not unfrequently attained by intelligent lads in attending a single course of twenty-eight lectures. It may be argued that the incompetent teacher will be checkmated by not producing "results," and consequently not becoming entitled to payment, but that would be to ignore what is due to the pupils who are betrayed into wasting their time and opportunities with useless teachers bearing the stamp of the Department. This may be illustrated plentifully from the reports of the examiners; for instance, from those upon the sciences of most interest to the readers of this Journal,—Chemistry and Botany. With respect to the elementary stage of Chemistry, Dr. ROSCOE and Professor RUSSELL say, "whilst admitting that "much good work is being done, it is also no less "certain that many of the teachers have not had the "opportunity of acquiring sufficient knowledge or "experience to enable them to give satisfactory syste- "matic instruction." Again, speaking of the advanced stage, the same examiners "strongly urge on the "Department the necessity of encouraging to the "utmost the formation of classes in the advanced "stage under competent teachers." The examiner in Botany, Professor THISELTON DYER, says it is plainly "evident that in each year many of the teachers are "quite incompetent to teach the subject. They seem "to content themselves, in fact, with teaching a "minimum in the most mechanical manner possible, "and obviously (from the uniformity of answering) "out of some inefficient manual compiled as a literary "venture by some person more or less ill-informed "as to the fundamental principles of the subject." It is therefore not so surprising to learn that the structure of the inflorescence of a daisy, which was one of the flowers set in the elementary stage, "was "generally misunderstood, and described as if it were "a flower, the involucre being treated as a calyx and "the florets of the ray as petals;" or that the vernal grass proved equally disastrous in the advanced stage, a large proportion of the candidates being evidently in total ignorance as to the structure of the gramineous inflorescence.

Professor THISELTON DYER is of opinion, and we think most people will agree with him, that as a temporary expedient a great improvement would be effected if groups of centres where scientific instruction is given would combine to secure the help of really efficient teachers, with an aptitude to instruct in particular subjects rather than a general disposition to undertake any in which they think they see a prospect of earning a grant. But he considers the present deplorable state of things must always be more or less irremediable until the work the Department is doing in training the teachers themselves gradually effects a leavening of the whole mass. In the face of such an opinion, and remembering that the reorganized "Normal School of Science and Royal School of Mines" at South Kensington was primarily intended for the instruction of teachers and of students of the industrial classes selected by competition, whilst other students were only to be admitted, so far as there might be accommodation for them, upon payment of fees fixed at a scale sufficiently high to prevent undue competition with institutions that do not receive State aid, it is not unreasonable to scan the Report for indications as to the rate at which the leavening process is going on. But it cannot be affirmed that the outlook is very promising. Of 78 students who received instruction in Chemistry during the session only 24 were Government students, the other 54 being private students, paying fees; of 31 who received instruction in Physics 13 were Government students; and out of 20 who were taught in Biology (including Botany) there were 13 more. These fifty students we presume, therefore, represent, as far as these three important sciences are concerned, the extent to which this "science school of the highest class" was during the year 1882 made available to the two kinds of students for whom it was primarily intended, and if from these fifty be deducted a proportion of the exhibitioners and scholars "selected by competition" it will be seen that the proportion of leaven introduced into the mass of nearly two thousand teachers is a very moderate one.

THE INTERNATIONAL PHARMACEUTICAL EXHIBITION AT VIENNA.

ON Saturday next, the 11th inst., the first of what is designed by the promoters to be a series of international pharmaceutical exhibitions, held in different parts of the world, will be formally opened in Vienna by His Imperial Highness the Archduke KARL LUDWIG, brother of the Emperor of Austria, and a hearty invitation to be present at the ceremony has been issued by the General Committee to pharmacists at home and abroad. It is perhaps unfortunate that such a movement was not initiated in a country more freely visited by foreigners; but this, if it be a disadvantage, is somewhat compensated by the fact that it is under the management of men who well understand the essentials to the success of such an exhibition, the Committee being presided over by Herr ANTON VON WALDHEIM, a former President of the International Pharmaceutical Congress and the present President of the International Pharmacopœia Commission. Notwithstanding the distance, we have reason to believe that between the 11th and the 27th of this month, when the exhibition will close, several Englishmen will be numbered among the visitors, and we hope to be able to lay before those pharmacists who have to stop at home an account of the most interesting of the objects shown.

We understand that there will be about three hundred exhibitors; most of these, as might be expected, will belong to the Austro-Hungarian empire, but Germany, Russia, France, England, America, Italy, Turkey, Spain, Portugal, Belgium, Holland, Denmark, Sweden, Norway, Switzerland and Roumania will be represented. Numerous scientific societies, also, have placed at the disposal of the Committee objects of very great interest, especially many illustrative of the conditions of pharmacy in the olden times.

The distinctions to be accorded for meritorious exhibits are of three kinds, diplomas of honour, silver medal diplomas and gold medal diplomas. These are to be awarded on the report of a committee of thirty-six jurors, nominated by the Executive Committee, care being taken that, as far as possible, every State participating in the exhibition shall be represented. Eighteen of these thirty-six jurors will deal with the class including drugs, chemical products, and pharmaceutical preparations and wares intended for medicinal use; the remaining eighteen being divided into groups who are to be intrusted with the other five classes devoted mainly to literature, pharmaceutical antiquities, scientific instruments and pharmaceutical apparatus. Where necessary the jurors are to be authorized to avail themselves of the assistance of experts, who also are to be nominated by the General Committee. The jurors are to meet on the 15th inst., and are to complete their labours by the 20th, immediately after which the list of awards will be published.

It only remains to repeat that the exhibition is to be held in the rooms of the Imperial Agricultural Society, which are beautifully situated in the Park-Ring, opposite the City Park. In the Rotunda, which formed part of the building erected for the universal exhibition of 1873, there will be held simultaneously an International Electric Exhibition; whilst two of the principal Austrian Pharmaceutical Associations will hold their annual gatherings in Vienna between the 20th and 25th of the month.

THE USE OF THE ROYAL ARMS.

It will be observed, from the correspondence laid before the Council at its meeting on Wednesday last that the Board of Trade recognizes the inconvenience which might be consequent upon the passing of the clause in the Patents Bill relating to the use of the coat of arms in its present form, and has suggested an amendment which the Council might adopt and procure to be moved upon the report of the Bill. Even in its amended form the clause would not be free from objection; but the real abuse at which the Government wishes to strike,—the fraudulent use of the arms by unscrupulous patent agents,—may be difficult to reach with a less stringent provision, whilst it is hardly probable that the law officers of the Crown would attempt to enforce a vexatious construction which it is now on record the clause is not intended to bear. The Patents Bill as amended was to be considered on Friday, and on Thursday Sir John Lubbock gave notice that he would move a fresh amendment, which is identical with that approved by the Council. It may, therefore, be assumed that a satisfactory decision will be arrived at, and we think that the thanks not only of chemists and druggists, but of the public generally, are due to the Council of the Pharmaceutical Society for the judicious manner in which it has brought the subject under the attention of the Government.

It appears from a remark made on Wednesday by Mr. Mundella on the occasion of receiving a deputation of Scottish graduates that the Government still hopes to be able to pass the Medical Acts Amendment Bill during the present session. It does not, however, appear to have been referred to by the Prime Minister in his statement as to the business before Parliament made on Thursday.

* * *

The Petroleum Bill was again set down for second reading in the House of Lords on Friday.

* * *

The British Medical Association commenced its fifty-first annual meeting at Liverpool on Tuesday last. The report showed that there had been an increase of nearly five hundred members since the meeting last year, the total number at the commencement of July being 10,050. The revenue for the year 1882 was £19,076, and the expenditure £16,288. A lively scene seems to have been provoked during a discussion of the bye-laws by the proposal of an amendment intended to exclude homœopathists from the Association, which, however, was not carried. On Wednesday it was decided that the meeting for 1884 should be held in Belfast, Dr. Cumming, of that city, being chosen President-elect.

* * *

The Honorary Secretaries of the Local Executive Committee at Southport have issued a circular stating that the Lancashire and Yorkshire and West Lancashire Railway Companies have arranged to issue season tickets at very cheap rates, permitting the holders to travel to and fro, as often as may be desired, between Southport and the chief stations on their respective lines for the period of a fortnight, covering the session of the Association. On production of the Association ticket or letter of invitation, also, return tickets will be issued to or from Southport from or to Lancashire and Yorkshire stations at a single fare, available on the day of issue only. Further, it may be convenient to intending visitors to the British Pharmaceutical Conference to know that the London and North Western Railway Company will attach through carriages to Southport to the carriages leaving Euston at 7.15 a.m., 11 a.m., 1.30 p.m., 3 p.m., and 4 p.m. on the 17th, 18th, and 19th of September.

* * *

We have received a copy of the programme of the International Medical Congress, with special reference to the Colonies, which is to be held in Amsterdam on the 6th, 7th and 8th of September. From it we learn that special reports by various eminent men will be presented to the Congress upon quarantine, the special education of colonial doctors; the hygiene of unhealthy professions, cultivations and trades in the colonies; the modifications which certain diseases, and especially infectious ones, undergo under the influence of tropical climates; phthisis in the colonies and tropical climates; and the treatment of exotic and tropical diseases in temperate climates. The President of the Organization Committee is Professor Stokvis, of Amsterdam.

* * *

We regret to have to announce that Mr. William Henry Slater, who was elected an Annuitant in 1878, died on the 29th ult., at the age of 59, from softening of the brain.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, August 1, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Butt, Churchill, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht and Williams.

The minutes of the previous meeting were read and confirmed.

DIPLOMAS.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Baily, Edward.
Barnes, James Burden.
Bessell, James Walter.
Corder, Edward.
Corder, Walter Shewell.
Crow, William Edward.
Dott, David Brown.
Gulliver, Walter Frederick.
Hopkins, William Richard.
Houfe, Robert William.
Ivatt, Albert.
Johns, Henry Benjamin Jeffery.
King, Arthur.
Presbury, Herbert Henry.
Ranken, Charles.
Rees, David.
Williams, William Lloyd.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Baily, Edward ....Ramsgate.
Barnes, James Burden ....London.
Bessell, James Walter............Ludlow.
Corder, Edward ....Norwich.
Crow, William Edward ....Louth.
Dott, David Brown ... .Edinburgh.
Hopkins, William Richard......Aberystwith.
King, Arthur ....Norwich.
Presbury, Herbert Henry ......Chaddesden.
Ranken, Charles ....Sunderland.
Rees, David ....London.

Chemist and Druggist.

The following registered chemist and druggist, who was in business on his own account before August 1, 1868, having tendered his subscription for the current year, was elected a "Member" of the Society:—

Anderson, Alexander Black ...Dundee.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Bowden, Thomas Lemon ......Keynsham.
Bowman, Edmund ....Edinburgh.
Gordelier, Frank Heward ......Sidcup.

ASSOCIATES.

The following, having passed the Minor examination, and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Adamson, Joseph William ......Epworth.
Arthur, John........................Chesterfield.
Badcock, Hy. Southgate R.......South Petherton.
Beale, William Scott ....London.
Brown, Joseph ....Walker-on-Tyne.
Burnett, Joseph Fearon ....Hyde.
Charge, Arthur William.........Chichester.
Crofts, John Ernest............ ..Leicester.
Crompton, William ....Bury.
Davies, Edward Charles James..London.
Denham, Albert Shaw............Preston.
Dewes, George ... .Wolverhampton.
Dickson, John ....Dumfries.
Edmunds, Henry Herbert ......Mere.
Elliott, Stephen James .. ..Preston.
Haddock, James ....Bedford Leigh.
Hart, Frederick Charles ....Tongham.
Hartley, Walter Edward.........London.
Heath, Walter Edwin ....Coleshill.
Hudson, Alfred Wickens..... ...London.
Jones, David.........................Carnarvon.
Kay, Thomas Wilkinson ... .Manchester.
King, Frederick Herbert.........Market Drayton.
Lambert, Oliver ....Hull.
Lees, James ....Leighton Buzzard.
Metcalf, Rowland Alfred ......Uxbridge.
Mowatt, John Rodman ....London.
Munkman, Robert Allen ......Boston.
Parker, Edmund Lloyd Philips..Nottingham.
Pottage, Edwin.....................Beverley.
Reynolds, Richard Freshfield...Leeds.
Roberts, Edmund..................Upper Norwood.
Rowland, Langshaw ....Wrexham.
Scupham, Herbert ....Ulceby.
Walker, George Edward.........Royston.
Wiggin, John Chinery............Ipswich.
Wilson, David William Richard.Thirsk.

Modified.

Bottomley, Lawrence Whinray..Sheffield.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Allison, Henry ....Birmingham.
Aspinall, John William ....Ulverston.
Barker, James Herbert Bond...Mold.
Bray, John ....Lochmaben.
Buxton, Alfred......... ....Stafford.
Clayton, George ....Manchester.
Cobham, George William ......Gravesend.
Crofts, Robart ....Canterbury.
Guest, William Joseph ....Walsall.
Harold, John P. ....London.
Haywood, William Henry ......Liverpool.
Heap, Arthur ... .Coventry.
Hulland, James ....Bath.
Jeffcoat, Joseph George.........London.
Johnstone, Edward Straus ......Whaley Bridge.
Jones, John ....Llandovery.
Keyzor, Alfred Abraham ......London.
Lawrenson, John..................Radcliffe.
Lewis, Thomas......................Wednesbury.
Lord, William Butler ....Lancaster.
Miller, William Gow ....Wick.
Morris, John........ ....Birkenhead.
Patchett, John ....Halifax.
Robinson, Richard Hardy ......Wainfleet.
Rogers, Charles Henry ....Ipswich.
Sewell, Thomas Arthur Wm....Lee.
Shand, Alexander, jun. ....Dunfermline.
Simpson, James William.........Maidstone.
Squire, George ....Barnsley.
Walter, John Albert ....Ampleforth.

Warren, Thomas ....Hingham.
West, George William.............Stokesley.
Williams, George Whitfield ...Cardiff.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Addition to the Register.

The Registrar reported that—

FitzWilliam Bennett Townley, 2 Commercial Place, Landport,

having made a statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and this declaration having been duly supported by a qualified person, his name had been placed on the Register.

Superintendents of Written Examinations.

The following list of Superintendents and Deputy-Superintendents of written examinations for the ensuing year was agreed to:—

Aberdeen ....Kay, James Petrie.
Birmingham ....Southall, William.
Brighton ....Gwatkin, James Ross.
Bristol ....Stroud, John.
Cambridge ....Deck, Arthur.
Canterbury ....Bing, Edwin.
Cardiff ....Munday, John.
Carlisle ....Thompson, Andrew.
Carmarthen ....Davies, Richard Morgan.
Carnarvon ....Lloyd, William.
Cheltenham ....Smith, Nathaniel.
Darlington ....Robinson, James.
Douglas, Isle of Man ......Brearey, William A.
Dundee ....Hardie, James.
Edinburgh ....Stephenson, John B.
Exeter ....Broom, William Willey.
Glasgow ....Kinninmont, Alexander.
Guernsey ....Arnold, Adolphus.
Hull ....Bell, Charles Bains.
Inverness ....Galloway, George Ross.
Jersey ....Ereaut, John, jun.
Lancaster ....Bagnall, William Henry.
Leeds ....Reynolds, Richard.
Lincoln ....Maltby, Joseph.
Liverpool ....Symes, Charles.
London ....Taylor, George Spratt.
Manchester ....Wilkinson, William.
Newcastle-on-Tyne ....Martin, Nicholas Henry.
Northampton ....Bingley, John.
Norwich ....Sutton, Francis.
Nottingham ....Bolton, Charles Alfred.
Oxford ....Prior, George Thomas.
Peterborough ....Heanley, Marshall.
Sheffield ....Ward, William.
Shrewsbury ....Cross, William Gowen.
Southampton ....Dawson, Oliver Robert.
Truro ....Percy, Thomas Bickle.
Worcester ....Virgo, Charles.
York ....Sowray, Joseph.

Deputy-Superintendents of Written Examinations.

Aberdeen ....Glover, William K.
Birmingham ....Churchill, William John.
Brighton ....Savage, William Wallace.
Bristol ....Pitman, John.
Cambridge ....Hoare, William Parker.
Canterbury ....Amos, Daniel.
Cardiff ....Coleman, Alfred
Carlisle ....Hallaway, John
Carmarthen ....Davies, R. Morgan, jun.
Carnarvon ....Francis, James
Cheltenham ....Barron, William
Darlington ....Hutchinson, Rev. E.
Douglas, Isle of Man ......Brearey, Arthur W.
Dundee ....Kerr, Charles
Edinburgh ....Ainslie, William
Exeter ....Harris, Henry William.
Glasgow ....Davison, Thomas.
Guernsey ....Collenette, Adolphus.
Hull ....Baynes, James.
Inverness ....Galloway, George.
Jersey ....Ereaut, John.
Lancaster ....Wilcock, John.
Leeds ....Smeeton, William.
Lincoln ....Battle, John Scoley.
Liverpool ....Sumner, Robert.
London ....Bremridge, Richard. Knapman, John W. Holmes, Edward M.
Manchester ....Wilkinson, George.
Newcastle-on-Tyne ....Stuart, Charles Edward.
Northampton ....Mayger, William D.
Norwich ....Corder, Octavius.
Nottingham ....Parker, William H.
Oxford ....Thurland, Henry.
Peterborough ....Buckle, Frank George.
Sheffield ....Wilkinson-Newsholme, G. T.
Shrewsbury ....Blunt, Thomas P.
Southampton ....Spearing, James.
Truro ....Anstey, John U.
Worcester ....Lunn, Thomas.
York ....Wilson, Thomas William.

FINANCE.

The report of this Committee recommended sundry accounts for payment. It also recommended that the Committee be authorized to sell out a sufficient amount of stock to complete the purchase of freehold ground rents at Paddington Green, Strawberry Hill and Wimbledon, which purchases had been already sanctioned by the Council.

The Council went into committee whilst the President explained the above business in detail. On resuming, the report and recommendations of the Committee were received and adopted.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow, aged 72, of a pharmaceutical chemist and member, who was also an annuitant on the fund.

£10 to a former member, in very infirm health. Applicant has had seven previous grants.

£10 to the widow, aged 71, of a registered chemist and druggist.

£10 to the widow, aged 74, of a pharmaceutical chemist member.

£10 to a registered chemist and druggist.

£5 to the widow of a chemist and druggist member.

The Secretary had reported that a grant of twenty guineas made in February last to aid in securing the election of an orphan had been expended successfully, and the child had been elected.

The Committee had declined to entertain one application which had been made for assistance.

The Isherwood Orphans.

Mr. Savage said he had recently had an opportunity of seeing the little girl Isherwood and he found that she was very comfortably domiciled. The gentleman with whom she was placed had died, but his widow carried on two businesses, the one a chemist's by the aid of a qualified assistant and the other that of a general trade, in which the girl Isherwood assisted, and her adopted mother said she could not think of parting with her.

Mr. Williams said this was a very gratifying statement and he hoped that its publication would have the effect of inducing some one to take the charge of the elder boy, who was now of an age when he ought to be doing something to earn his living.

The Vice-President said he was glad this subject had been mentioned, and he hoped some kind-hearted person would come forward and help. The lad was now between thirteen and fourteen; he was an intelligent boy, but of rather delicate health. The other boy, who was about nine, was still at school.

The Secretary read a letter which had been received from a widow who had received three separate grants of £15 each, at intervals since 1877, saying that she was no longer in need of assistance and enclosing a postal order for 5*s.* as a small contribution to the Benevolent Fund.

The report and recommendations of the Committee were received and adopted.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
June . . .	Day . . .	739	38	16	28
	Evening . .	148	16	2	7

	No. of Entries.		
Circulation of books.	Town.	Country.	Total.
June	170	118	288

Carriage paid, £1 7*s.* 2*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Bentley (Professor R.), Student's Guide to Structural, Morphological, and Physiological Botany, 1883. From the AUTHOR.

Coles (O.), List of Works on Dentistry, published between the years 1536 and 1882. From the BRITISH DENTAL ASSOCIATION.

Hooker (J. D.), Flora of British India, part 10. From H.M. SECRETARY OF STATE FOR INDIA.

The Committee recommended the purchase of the undermentioned works:—

Baillon (H.), Traité de Botanique Médicale Phanerogamique, 1883, 2 fascicules.

Köhler's Medizinal-Pflanzen.

Lindley (J.), School Botany.

The Librarian had informed the Committee that the annual meeting of the Library Association would be held at Liverpool in September. The Committee recommended that the Librarian should attend the meeting.

The President had afterwards recommended the purchase of another copy of Sachs' Botany.

Curator's Report.

The Curator had reported the attendance in the Museum to have been:—

	Total.	Highest.	Lowest.	Average.
Morning .	520	49	4	20
Evening .	147	13	2	7

Estimates had been obtained for new Museum cases in the examination room, and the Committee recommended that Mr. Howlett's estimate for £221 5*s.* be accepted.

Professors Redwood and Bentley had attended and reported satisfactorily as to their respective classes.

Professor Attfield had sent in his usual statistical report as to the Practical Chemistry class. The whole class had worked well, the progress made had been satisfactory, and the conduct of all unexceptionable.

The PRESIDENT asked for authority to carry out during the vacation certain small alterations, whitewashing and cleansing, etc.

This was agreed to, and the report and recommendations of the Committee were unanimously adopted.

Resignation of the Assistant-Curator.

The PRESIDENT reported that the Assistant-Curator in the Museum, Mr. Elborne, had written a letter tendering his resignation, as he had recently obtained the appointment of Assistant-Lecturer at Owens College, Manchester. He thought it was not desirable at the present moment to make a permanent appointment in the place of Mr. Elborne, but suggested that the Curator be authorized to employ such temporary assistance as he required for the present.

The letter was ordered to be entered on the minutes, and the resignation accepted.

The VICE-PRESIDENT said he understood that there had been a sharp competition for the post at Owens College, and he believed Mr. Elborne owed his success in great measure to the position he had held in connection with the Pharmaceutical Society.

Mr. GREENISH expressed his pleasure at Mr. Elborne's success, he having discharged his duties greatly to the satisfaction of the Committee.

GENERAL PURPOSES.

The report of this Committee included the reports of the Professors as to the School of Pharmacy prizes, the report of the Examiners appointed to conduct the competition for the Pereira Medal, etc., and Professor Bentley's report on the Herbarium Prize. The purport of these reports was as follows:—

Chemistry and Pharmacy.

Professor Redwood reported that at the examination held at the termination of the second course of five months four competitors had obtained sufficient marks to entitle them to recognition. He also reported that there had been twelve competitors for the Silver Medal at the sessional examination, of whom seven had distinguished themselves. The session had been generally a successful one, as indicated by the number of students from the School who had passed the Major examination during the session.

Materia Medica and Botany.

Professor Bentley reported the result of the examination held at the termination of the second course of five months. Two competitors were entitled to recognition. In the sessional examination for the Silver Medal, thirteen students had competed, all of whom acquitted themselves satisfactorily in the *vivâ voce* examination on medicinal plants and the diagnosis of the natural orders, and eleven of them did well in the written examinations. The Professor expressed his satisfaction at the working of the system of examining the class at the end of each lecture, and he reported most satisfactorily on the excellent conduct of the students generally.

Herbarium.

For the Herbarium Prize only two collections had been submitted, the best of which contained about 350 specimens, and for this Professor Bentley recommended the award of a bronze medal. The second contained over 200 specimens and also deserved recognition.

Practical Chemistry.

Professor Attfield reported that no less than twenty-three students competed for the prizes in his class, and that twelve of them had obtained sufficient marks to entitle them to medals and certificates.

Council Examination Prizes.

The examiners, Messrs. Plowman and Southall, appointed to conduct the examinations for these prizes, reported that there were thirteen competitors, two of whom were entitled to recognition. They had been unable to award the Pereira Medal, as no competitor had obtained the standard number of marks required, but recommended the award of the Society's Silver and Bronze Medals.

The report, which included the usual letter from the Solicitor, stating the progress made with cases which had been placed in his hands, was as usual considered in committee. On resuming, the report and recommendations of the Committee were received and adopted.

On the motion of the PRESIDENT, seconded by the VICE-PRESIDENT, it was resolved—

"That the best thanks of the Council be given to Messrs. Plowman and Southall for having conducted the Council Prizes examination; to Messrs. Ekin and Taylor for having conducted the Jacob Bell Memorial Scholarship examination; and to Professor Bentley for his report on the Herbarium competition."

Prize Awards.

The following awards were made on the recommendation of the General Purposes Committee:—

Chemistry and Pharmacy.

[Five months' course.]

Bronze Medal	Lewis Walter Hawkins.
Certificates of Merit	John Chinery Wiggin. Ernest James Reynolds. John Rodman Mowatt.

[Ten months' course.]

Silver Medal	David Rees.
Certificates of Honour	Francis Ransom. Edward Baily. David Low.
Certificates of Merit	Charles Ranken. William Edward Crow. Thos. Southall Dymond.

Botany and Materia Medica.

[Five months' course.]

Bronze Medal	John Chinery Wiggin.
Certificate of Merit	Ernest James Reynolds.

[Ten months' course.]

Silver Medal	Edward Baily.
Certificates of Honour	Francis Ransom. William Edward Crow. William Lloyd Williams. Equal. Charles Ranken. David Low. Edward Ernest Sewell.
Certificates of Merit	Thos. Southall Dymond. William Johnston. Arthur Pumphrey. John Chinery Wiggin.

Practical Chemistry.

Silver Medal	William Edward Crow.
Bronze Medals	Thos. Southall Dymond. David Rees.
Certificates of Honour	Charles Ranken. John Chinery Wiggin. William Lloyd Williams. Bernard Keene.
Certificates of Merit	Edward Baily. Francis Ransom. David Low. Edward Marsh. James Burden Barnes.

Herbarium Prize.

Bronze Medal	Thomas Stephenson.
Certificate of Merit	Frederick Miller.

Council Examination Prizes.

Pharmaceutical Society's Medal (silver); and Books value £3, presented by Mr. T. H. Hills.

William Lloyd Williams.

Pharmaceutical Society's Medal (Bronze); and Books value £2, presented by Mr. T. H. Hills.

Edward Baily.

Jacob Bell Memorial Scholarships.

The Committee appointed to make the award of the Jacob Bell Memorial Scholarships for the ensuing session, subject to the approval of the Council, reported that twenty-five candidates had presented themselves at the following centres:—Birmingham, 1; Cambridge, 1; Canterbury, 2; Cardiff, 1; Carnarvon, 1; Darlington, 1; Edinburgh, 1; Exeter, 1; Lincoln, 1; Liverpool, 2; London, 8; Manchester, 2; Oxford, 1; Sheffield, 1; Shrewsbury, 1. Of these, five had obtained more than the minimum number of marks requisite to entitle them to the award.

The envelopes bearing the mottoes of the successful candidates having been opened, their names were found to be

Fraser McDiarmid,
and
Robert Wynn Charles Pierce.

The report was received and adopted.

Mr. Hills said it was very satisfactory to find that five men had obtained enough marks to gain a scholarship.

The Education Scheme.

Mr. Schacht said he wished to take the opinion of the Council as to what it was desirable to do in connection with the education scheme. He would suggest that at the meeting in October a resolution should be submitted and the whole subject could then be discussed. It seemed a pity that the subject should be allowed to lapse, and by that time, the Council would be able to judge as to the probability of an Amended Pharmacy Act being passed, and might be induced, if necessary, to undertake substantial alterations independently of any amendment of the Act.

Mr. Williams remarked that if this were done, it would be very desirable that the scheme as drawn up by the Committee and approved by the Council should be submitted to the Solicitor, in order to have his deliberate opinion, and, if necessary, that of counsel, as to how far the proposed changes were or were not within the power of the Council to carry out. If there were no power to make the alterations, it would be mere waste of time to discuss the subject.

Mr. Richardson did not see that it could be waste of time to discuss such an important matter.

Mr. Schacht thought the proper time to take the Solicitor's opinion would be later, when the Council had determined on what it desired to do.

Mr. Hampson thought it unwise to continue the present conversation, which would necessarily result in discussing the whole scheme. The Committee had issued its report, which had been accepted by the Council, and there the matter ended for the present. He thought reopening the discussion at present would only prejudice the passing of an amended Pharmacy Bill.

Mr. Borland thought if Mr. Schacht's proposal were carried out it would be very desirable that Mr. Williams's suggestion should be adopted. Before the Council came to any definite conclusion as to the adoption of a new educational scheme it was very desirable that the legal position should be very strictly defined.

Mr. Schacht thought it would be premature to obtain the opinion of the Solicitor until the Council had decided whether it was desirable to take any action before an amended Pharmacy Act was passed. The report of the Committee had been agreed to, and his object was to ascertain whether any further step should be taken. He saw no objection to the Solicitor being present when the discussion took place, but he thought the Council should first decide what it wanted to do before ascertaining whether it was legal.

Mr. Williams thought it was no use coming to any conclusion until the Council knew whether it was legal or not.

Mr. Radley said the opinion of the Solicitor could be obtained on the general principle embodied in the report of the Committee.

Mr. Schacht said he had no objection to the Solicitor's opinion being obtained.

The President said the matter could not be more fully discussed then, but any member could give notice of a motion for the October meeting.

Mr. Williams then moved—

"That the opinion of the Solicitor be taken as to the legal power of the Council to carry out the scheme embodied in the report of the Committee."

Mr. Hampson seconded the motion.

The VICE-PRESIDENT thought it would be better to wait and see whether there was any chance of passing an amended PharmacyBill that would give the Council the powers required.

Mr. WILLIAMS, on the other hand, thought if it were shown that the Council could not carry out what was desired in the way of education under its present powers, it would be a strong argument to help the passing of a new Bill.

The PRESIDENT said if Mr. Schacht gave notice of motion for the October meeting Mr. Williams could propose an amendment, such as he had now proposed, but on consideration he did not think he could receive the motion at present as notice had not been given according to the standing orders.

THE HANBURY MEDAL.

The following report was received:—

"Pharmaceutical Society of Great Britain,
"17 Bloomsbury Square.

"We, the undersigned adjudicators, appointed under the provisions of the Deed of Settlement of the Daniel Hanbury Memorial Fund, award the second Hanbury Gold Medal to

JOHN ELIOT HOWARD, F.R.S.,

for his distinguished excellence in the prosecution of original research in the natural history and chemistry of drugs.

(Signed)	"John Lubbock...	President of the Linnean Society.
(Signed)	"W. H. Perkin ...	President of the Chemical Society.
(Signed)	"M. Carteighe ...	President of the Pharmaceutical Society of Great Britain.
(Signed)	"John Attfield ...	President of the British Pharmaceutical Conference.
(Signed)	"Henry B. Brady..	Pharmaceutical Chemist, nominated by the Presidents of the Pharmaceutical Society of Great Britain and the British Pharmaceutical Conference.

"*July*, 1883."

THE NORTH BRITISH BRANCH.

A resolution was passed authorizing the closing of the Society's premises in Edinburgh, from August 18 to September 17, for the vacation.

THE BRITISH PHARMACEUTICAL CONFERENCE.

The President and Vice-President, with Messrs. Butt, Greenish, Hills, Radley, Savage, Schacht and Williams, were appointed delegates from the Council to attend the Conference at Southport in September.

THE PATENTS FOR INVENTIONS BILL, ETC.

The PRESIDENT said he had seen Mr. Farrer, of the Board of Trade, on the subject of the clause in the Patents Bill forbidding the unauthorized use of the royal arms in connection with business under a penalty of £20. He understood that the cause of this clause being introduced was the use of the royal arms by certain patent agents, which had led to misunderstanding, persons from the country having entered private offices, and been led to part with their money under the impression that they were visiting the Government Patent Office. Mr. Farrer said it had not occurred to the authorities that the clause would interfere with the use of labels, and he invited him to send the Department a letter on the subject. The following correspondence was the result:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.
"T. H. Farrer, Esq., "*July* 18, 1883.
"Secretary, Board of Trade,
"Whitehall, S.W.

"Dear Sir,—I am requested by the Council of this Society to draw the attention of the President of the Board of Trade to the wording of clause 94 of the 'Patents for Inventions Bill' as follows:—

"94.—'Any person who without due authority assume or uses in connection with any trade or business, the royal arms, or any arms so nearly resembling the same as to be calculated to deceive, shall be liable on a summary conviction to a fine not exceeding £20.'

"The use of labels and wrappers bearing an impression of the royal arms is very general among manufacturing chemists, pharmaceutical chemists, chemists and druggists, drysalters, grocers and village shopkeepers, and I am directed to enquire if it is the intention of the Board that the users of such labels, etc., shall be liable to the penalty mentioned in the clause.

"I enclose a few specimens, obtained from the stock of one printer only, to illustrate the kind of labels, etc., referred to, and I may remind you that biscuits, nuts, and fruit of all kinds are very commonly sold in bags bearing an impression, more or less artistic, of the royal arms.

"A reference to the specimen book of any type founder will also show the enormous number of designs in which the royal arms form either the whole or a part.

"Soliciting the favour of an early reply,
"I am, dear Sir,
"Yours faithfully,
"M. CARTEIGHE,
"*President.*"

A second letter was addressed to Mr. Farrer, on July 27th, asking for a reply, in order that the subject might be considered by the Council at its next meeting.

The following reply was received:—

"(Immediate.)
"The Secretary,
"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, W.C.
"Board of Trade,
"London, S.W.
"*July* 28, 1883.

"Sir,—I am directed by the Board of Trade to acknowledge the receipt of your letter of the 27th instant, in respect to the provisions of clause 103 of the Government Patents Bill (as amended).

"In reply, I am to state, for the information of the President of the Pharmaceutical Society, that it appears to the Board of Trade very doubtful whether the clause in question would apply in the manner the Society anticipate. An amendment of the clause, is, however, under consideration, and the Board of Trade will forward it to you when prepared, and will be glad to consider the same with the representations of the Society.

"I am to add that, if agreed on, the clause might be proposed by some member on behalf of the Society on report of the Bill in Parliament.

"I am, Sir,
"Your obedient servant,
"HENRY G. CALCRAFT."

"(Immediate.)
"Board of Trade,
"London, S.W.
"The Secretary, "*July* 30*th*, 1883
"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, W.C.

"Sir,—Referring to the letter from this Department of the 28th inst., touching the provisions of clause 103 of the Government Patents Bill, I am now directed by the

Board of Trade to transmit to you, for the consideration of the Pharmaceutical Society, copy of an amendment of the terms of the clause in question, which the Board of Trade are disposed to think will meet the case.

"I am to request that the Board of Trade may receive the observations of the Society on this amendment at as early a date as possible.

"I am, Sir,
"Your obedient servant,
(Signed) "HENRY G. CALCRAFT."

"*Clause* 103, *page* 33. Leave out from beginning of clause to and inclusive of 'deceive' in line 17, and insert 'Any person who, without the authority of Her Majesty or any of the royal family, or of any Government department, assumes, or uses in connection with any trade, business, calling, or profession the royal arms, or arms so nearly resembling the same as to be calculated to deceive, in such a manner as to be calculated to lead other persons to believe that he is carrying on his trade, business, calling or profession by or under such authority as aforesaid.'"

Mr. HAMPSON asked if the President had referred in his interview to the use of the royal arms on specie jars, and so on. He hoped the clause would be withdrawn.

Mr. SCHACHT thought it was the general opinion when the matter was mentioned last month that the principle of the clause was right, and that there was no desire to defend an improper assumption and use of the royal arms. All, he thought, that was required was that persons who had labels in use having the royal arms upon them, should have fair time allowed to get rid of them. There was no more right to take liberties with the royal arms than with the arms of any private individual.

Mr. HAMPSON said the use of the arms on a specie jar or labels was only for the sake of ornament. It was not for the purpose of leading the public to suppose there was any special authority to use the arms.

Mr. ANDREWS said there was no doubt the royal arms were sometimes used for the purpose of defrauding the public by making them believe that the person using them had a royal appointment. So far as the clause would prevent that, it would do good. As now amended he saw no objection to it.

The VICE-PRESIDENT said this was a much larger question than that of a few specie jars; there were millions of labels and bags thus ornamented in use in every branch of business. He was astonished to hear of persons putting the royal arms over their door improperly, and agreed that any attempt to impose on the public should be put down.

The PRESIDENT remarked that the question was raised principally with regard to labels. He thought it would be impossible to put a sudden stop to a custom which had grown up during many years, and which by many was supposed to be a loyal custom.

Mr. ROBBINS did not think the public had ever been deceived by seeing the royal arms in a chemist's shop or on his labels, but there was no doubt that some people had improperly put the arms over the door without authority, and this should be stopped. He did not think much injury would be done by the clause as it originally stood, though it might involve some little expense. The street in which his business was conducted had recently been renumbered, and he did not know that he had suffered by having to change his labels beyond the expense.

Mr. SAVAGE thought the amended clause was not open to objection.

Mr. GREENISH thought this subject required very careful watching. There had been no intention on the part of chemists and other tradesmen to deceive anyone by the use of the royal arms, and he must confess he was not prepared to sacrifice a considerable amount of property in the shape of labels. It did not appear to him that the amendment was satisfactory, and he should much prefer to see the clause withdrawn. It seemed to him that enacting such a clause to meet the evil which had been complained of was like using a Nasmyth hammer to crack a nut.

Mr. CHURCHILL said it had been found in the case of another Act of Parliament, that whereas one thing was intended by the Legislature, the Act was used by inspectors for another. It would be preferable to have a clause forbidding the use of the royal arms over the door.

Mr. WILLIAMS thought this was one of those irritating little pieces of legislation which would annoy the public without doing any good. It would probably be wholly inoperative, but at the same time it might be used to annoy people who were perfectly innocent. He did not believe the public was ever deceived by this sort of thing, and he hoped the Government would be requested to withdraw the clause altogether.

Mr. HAMPSON thought it would be well to get more information as to what was the intention of the Government.

The VICE-PRESIDENT thought the members of Council were all in accord with the Government in a desire to put down any attempt at deception or improper use of the royal arms; and the only question was whether the amended clause was free from the objection felt to it as originally drawn.

Mr. HILLS thought the clause even as amended was a very clumsy instrument for meeting the evil to which special reference had been made. Nearly every shop in Regent Street had the royal arms over the door, but no one was deceived by it.

After some further conversation, Mr. ROBBINS moved—

"That the President be instructed to reply to the letter from the Board of Trade to the effect that as amended the clause would be satisfactory to the Council."

Mr. ANDREWS seconded the motion, which was carried by 8 votes to 5.

A letter from Mr. Keyworth on the subject of the Patents Bill and Poisons law was read.

It was arranged, in accordance with custom, that no quorum would be formed for the Council meeting in September.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, July 31, Mr. Jones, of Royton, read a paper before the members of this Association, in the room, Church Institute, on "Coal and its Chemical Products."

The essayist first gave a brief account of the supposed formation of coal, and afterwards spoke of the products, commencing with coal-gas and describing its constituent gases; then of the ammoniacal liquor and its uses in pharmacy; lastly, of coal tar, and benzine, aniline and naphthaline, etc., made from it.

The paper was most interesting.

A vote of thanks was proposed by Mr. Buckley, seconded by Mr. Smith, and passed unanimously.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, July 26. Prof. Attfield, F.R.S., President, in the chair.

The following report of the Executive Committee was read:—

Annual Report.

"The Executive Committee of the School of Pharmacy Students' Association have transacted the business of the past session at three Committee meetings. At a meeting held December 14, 1882, the Secretary reported that nomination papers had been printed at the commencement of the session and forwarded to all members who had previously paid their annual subscription.

"Your Committee have transacted the following business:—

"At a meeting held December 14, 1882, the following gentlemen were appointed as a Committee of Reporters, to report upon the progress made in the various branches of science allied to pharmacy:—

Pharmacology ....Mr. H. G. Greenish.
Practical Pharmacy.........Mr. R. A. Cripps.
Botany ....Mr. J. O. Braithwaite.
Materia Medica ....Mr. W. Elborne.
Physics ....Mr. H. Allen.
Organic Chemistry ....Mr. W. R. Dunstan.
Inorganic Chemistry ......Mr. F. W. Short.
Analytical Chemistry ......Mr. C. Thompson.

"At a meeting held February 15, 1883, your Committee made a grant of 5*s*. from the Research Fund to Mr. E. Baily, for an examination of commercial specimens of dried alum. The results were brought before the Association in a paper read March 8, 1883, which was subsequently published in the *Pharmaceutical Journal.*

"At a meeting held July 26, 1883, your Committee made a grant of 10*s*. to Mr. R. A. Cripps, for an examination of the deposits occurring in the principal tinctures of the British Pharmacopœia.

"At a meeting held July 26, 1883, the following statement of the Committee of Reporters, including the work done by them during the session, was read by the Secretary on behalf of the Committee:—

"The Committee of Reporters on Science have since their appointment in December, 1882, held two meetings for the transaction of business.

"At a meeting held Thursday, January 4, 1883, Mr. Greenish was appointed Chairman, and Mr. Dunstan Secretary of the Committee.

"The only alteration in the constitution of the Committee has been the division of the subject of Pharmacy into two parts, Pharmacology and Practical Pharmacy. This change has been found to be entirely satisfactory.

"The following reports have been made by the members of the Committee during the session:—

"Two reports upon Materia Medica (New Remedies; Commercial Rhubarbs), by Mr. W. Elborne; Report upon Pharmacology (Convallaria Majalis), by Mr. H. G. Greenish; two Reports upon Analytical Chemistry (the Separation of Cadmium from Copper (in two parts); the Estimation of Carbolic Acid), by Mr. C. Thompson; Report upon Organic Chemistry (the Chemistry of Mel Boracis), by Mr. Dunstan; Report upon Inorganic Chemistry (the Alkali Manufacture), by Mr. Short; Report upon Physics (Secondary Batteries), by Mr. H. Allen; Report upon Practical Pharmacy (Notes upon the United States Pharmacopœia), by Mr. Cripps; Report upon Botany (Plant Movement), by Mr. Braithwaite.

"The above statement was approved by your Committee. At the meeting held July 26, 1883, the following letter from the Honorary Secretary was read by the President:—

'London, 17, Bloomsbury Square, W.C.,
'*July* 26, 1883.

'Dear Mr. President,—I regret that I have to place in your hands the trust of Honorary Secretary of the School of Pharmacy Students' Association, which I now hold. During the three years that I have filled the office, my spare time has been gradually more and more encroached upon, and I now feel it is necessary that my work with the Association should be in some measure lightened. I say 'lightened,' for I shall ever feel pleasure in taking every opportunity to advance those objects for which the Association was founded, and in the promotion of which it has been so eminently successful.

'I remain, dear Mr. President,
'Very sincerely yours,
'Wyndham R. Dunstan.

'To Professor Attfield, F.R.S.,
President of the School of Pharmacy
Students' Association.'

"Your Committee considered this letter in the absence of Mr. Dunstan, and in consideration of his services to the Association unanimously resolved that the members assembled in Annual Meeting be recommended to appoint an Assistant Secretary for the next session in order to relieve Mr. Dunstan of some of the work. This action being represented to Mr. Dunstan, he kindly consented to withdraw his resignation.

"With regard to the statistics of the Association, your Committee would draw attention to the following points: The number of members upon the books shows an increase of 10 upon last session. The gross attendance has been 301, an increase of 48 upon last session; the average attendance has been 21 per meeting against 18 of last session. Besides the Presidential Address at the opening, meeting, the number of communications read has been 25, an increase of 2 upon last session. Eleven of these have been reports already noticed, and 14 have been papers. The following is the list of papers:—

"Introductory Address, by the President—The Pharmacopœia as a Students' Manual; Original Investigation in Pharmacy, by Mr. E. M. Holmes; Genius, Talent, and Industry, and their Relation to Pharmaceutical Research, by Mr. R. W. Giles; Notes upon Practical Photography, by Mr. R. J. MacDermott; The Detection of Strontium, by Mr. F. Ransom; Dispensing Notes, by Mr. W. Johnston; Linnæus, by Mr. W. E. Crow; Note on Dried Alum, by Mr. E. Baily; Vortmann's Method for the Separation of Chlorides, Bromides and Iodides, by Mr. J. B. Barnes; The Synthesis of Uric Acid, by Mr. T. S. Dymond; The United States Pharmacopœia Process for the Estimation of Hydrocyanic Acid, by Mr. R. A. Cripps; Acetic Acid and its Derivatives, by Mr. H. S. Elworth; Some Abnornal Flowers, by Mr. E. E. Sewell; Some Old and New Theories concerning the Vegetable Cell, by Mr. C. Ranken; The Characteristics of the Principal Natural Orders, by Mr. H. Hamilton.

"Fifteen of these communications, six reports and nine papers, have been published in full by the Editor of the *Pharmaceutical Journal*, besides abstracts of all the others. The Treasurer's accounts, to be presently audited, show that the receipts have exceeded the expenditure by £1, which leaves a total balance of £11 8*s.* 1½*d.* in the hands of the Treasurer."

Messrs. T. S. Dymond and G. Fowler having been appointed Auditors, they examined the Treasurer's accounts and reported them to be correct.

After some observations upon the progress indicated by the Report from the President and Mr. H. G. Greenish (Vice-President), Mr. H. Allen, B.Sc., moved the adoption of the Report, and referred to the satisfactory condition of the Association, remarking that the Research Fund would enable the Association to still further extend its sphere of usefulness.

This was seconded by Mr. C. Thompson, and upon being put to the meeting was carried unanimously.

Mr. R. H. Parker (Vice-President) then moved "That an Assistant-Secretary be appointed for the ensuing session." In moving the resolution Mr. Parker observed that the prosperous condition of the Association during the last three years was mainly due to the exertions of the present Secretary, and this resolution would enable the Association to still have the benefit of his services.

Mr. W. E. Crow stated that as a member of the Executive Committee he was able to fully appreciate Mr. Dunstan's services to the Association, and he therefore seconded the resolution.

After some remarks from Mr. Thompson and the President, supporting the resolution, it was put to the meeting and carried unanimously.

Mr. H. G. Greenish then moved, and Mr. J. O. Braithwaite seconded, a vote of thanks to the President for his continued interest in the Association; after this had been unanimously carried by acclamation, the Association adjourned over the summer vacation.

Parliamentary and Law Proceedings.

Prosecution under the 17th Section of the Pharmacy Act, 1868.

At the Clerkenwell Police Court on Thursday, July 26, before Mr. Barstow, Edward Knight, gold and silver refiner, of 29A and 30A, Percival Street, Clerkenwell, London, E.C., was charged on two summonses, 1. For having sold to Alfred Wright, Assistant Secretary of the Chemists and Druggists' Trade Association of Great Britain a certain poison, to wit, cyanide of potassium, in a certain packet, the cover of which packet did not set forth the name of the poison and the name and address of the seller of the same. 2. That the said sale was effected, the purchaser being unknown to the seller and not introduced to the seller, in contravention of the statute in such case made and provided.

Mr. Henry Glaisyer, solicitor of the Chemists and Druggists' Trade Association, appeared for the prosecution, and defendant appeared in person.

The defendant pleaded guilty.

A fine of 50*s.* and costs was inflicted on the first summons, and 5*s.* and costs on the second.

Review.

The Extra Pharmacopœia of Unofficial Drugs and Chemical and Pharmaceutical Preparations.* By W. Martindale, F.C.S., and W. Wynn Westcott, M.B. Lond.

New preparations are constantly being prescribed by medical men, and pharmacists as well as wholesale druggists are often puzzled to know where to find the formula for a particular preparation ordered in a prescription. In some cases, too, the strength and appearance of new preparations differ when obtained from different firms. A book, therefore, giving reliable formulæ and doses and comprising all the latest information on new drugs has for some time been a desideratum, although the want has been to some extent met by Squire's 'Companion to the Pharmacopœia.'

The little work before us was written, as the authors tell us in the preface, with the view of describing new drugs and their uses, as well as new uses of drugs already official and non-official preparations met with in pharmacy, the area of selection being limited by the personal experience of the authors.

Mr. Martindale's well-known reputation as a pharmacist is a guarantee that the selection is by no means a small one and that it possesses the essential element for proving useful, viz., that it is the outcome of the experience of a considerable period. It is now sixteen years since the last British Pharmacopœia was issued, and the number of new drugs that have come into general use since that date is by no means small, to say nothing of the many that are still on trial.

The drugs are arranged alphabetically throughout the book. Under each heading the Latin and English name is given and the synonyms in ordinary use. The dose, description of the crude drug and tests for its purity, and the preparations in use, follow in order; and, finally, references as to the therapeutic uses and the doses given in different diseases, etc. This portion of the work, while serving as a guide to the pharmacist as to unusual doses, is chiefly of use to the physician or medical practitioner, to whom, as a sort of handy *précis* of the uses of new drugs, it must prove of considerable value.

The references have been compiled by Mr. W. Wynn Westcott, M.B. Lond., from the leading medical journals, hospital pharmacopœias, Ringer's 'Handbook of Therapeutics,' the *Pharmaceutical Journal*, and the *Chemical News*, each paragraph being accompanied by an abbreviated reference to the page of the book or journal from which it is taken. In this portion of the work, which must have been prepared at no small expenditure of time and trouble, it may be hoped that the author has availed himself of the help of Neal's 'Medical Digest.' It is exceedingly well done, and forms a most admirable example of the value of *précis*, as applied to medical literature.

There are two appendixes at the end of the book. The first is an alphabetical list of antiseptic applications and surgical dressings, which serves at the same time as an index to the descriptions in the body of the work and as an indication to chemists as to the size and

* London: H. K. Lewis. 1883. Fcap. 8vo. Pp. i.-viii., 1-313. 6*s.*

weight of the packages met with in commerce. The second appendix gives a list of histological preparations for staining, hardening and mounting microscopic objects.

The volume concludes with an excellent index and posological table, in which the official preparations of the British Pharmacopœia that have a dose assigned to them in that work are given in addition to those comprised in the present book.

We have rarely seen a work which is so thoroughly up to date or which more fully meets the wants of the readers for whom it is intended than the 'Extra Pharmacopœia,' and can strongly recommend it as a most handy, useful and reliable book to both the pharmacist and the busy medical practitioner. It fairly represents what can be done when medicine works in accord with pharmacy. The book is of small size and can be easily carried in the pocket, and in fact is convenient in every way. We venture to prophesy for it a considerable success.

Obituary.

Notice has been received of the death of the following:—

On the 5th of July, Mr. Joseph James Scholey, Chemist and Druggist, Hemsworth, Yorkshire. Aged 55 years.

On the 14th of July, Mr. Frederick Blackwell, Pharmaceutical Chemist, Stoke Terrace, Devonport. Aged 42 years.

On the 20th of July, Mr. Charles Milnes Hallam, Chemist and Druggist, High Street, Burton-on-Trent. Aged 51 years.

On the 27th of July, from heart disease, after an illness of about six months, Mr. George Kendall, Pharmaceutical Chemist, Masham, Yorkshire. The deceased gentleman was 63 years of age and had been a Member of the Pharmaceutical Society since the year 1844. He commenced business in Masham about forty years ago, and led a very active and useful life, taking a leading share in every good work for the advancement and improvement of the town and neighbourhood, so that his loss will be deeply regretted by his fellow-townsmen, by whom he was deservedly held in great esteem.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Royal Naval Reserve Dispensing.

Sir,—A few weeks ago you were good enough to give publicity to a short note of mine referring to the Royal Naval Reserve and Coast Guard dispensing. I called attention to the fact that at the several stations throughout the country, the duties of dispensing, etc., for the men who belong to these forces, were relegated to the medical man, the druggist being entirely ignored, and I suggested that this was a matter on which more light might, with advantage, be shed.

My note eliciting no reply from any reader of the Journal, I communicated with Mr. Bremridge in hopes that the Council of the Society might be induced to take up the matter, but from the courteous reply received from that gentleman, I learned that it had already been a subject of much consideration by the Members of the Council, but that as a Council they did not see that they could do anything at present.

As the question was one of considerable importance to myself, I determined to "take the bull by the horns" and lay the case before Mr. Campbell Bannerman, the present Secretary to the Admiralty.

If you think the subject of sufficient importance, perhaps you will give this, together with that right hon. gentleman's letter, which I append, a place in your next issue.

Quærens.

Copy of Mr. Campbell Bannerman's Letter.

"*Admiralty, S.W.*,
"*July* 5, 1883.

"Dear Sir,—I am directed by Mr. Campbell Bannerman to inform you that he has looked carefully into the subject of your letter of the 16th ultimo, and after consultation with the head of our medical department he has come to the conclusion that it would be impossible for him to take any steps towards altering the present regulations, which direct that all medicines and dressings are to be supplied by the medical officer.

"Any change in this respect would probably be attended with increased cost to the public, and as in many districts it would be difficult to get at a good chemist or druggist it is considered desirable to make one general rule and oblige our surgeon and agent to supply his own drugs.

"I remain,
"Yours faithfully,
"Gordon B. Voules."

Battley's Liquor Cinchonæ.

Sir,—If Mr. Ekin will kindly travel back with me to the time when nauseating doses of 20, 30, 40, and even 60 grains of powdered bark, or cup of thick decoction, every four hours, were given to patients shaking with ague or debilitated by more serious diseases, he will realize the benign influence of a preparation which produced the same effects on the pulse and system by a dose of a few drops. Such is the only possible rendering of Mr. Battley's label, "1 drachm is equivalent to 1 ounce of the finest bark or 12 ounces of the decoction."

During the thirty-three years I have used Battley's bark, I have never once met with a doctor or chemist who was mistaken by Mr. Battley's statement.

Let Mr. Ekin estimate the cost of making by any process 1 lb. of liquor containing the kinates of 7 or 8 lbs. of bark. Has Mr. Battley raised or lowered the price according to the market value of bark? Is it not a fact that for many years 32*s*. per lb. has been the price, and 20s. for the liquor opii sedativus.

I believe Mr. Battley, like several of our early pharmacists of note, was an apothecary, and I know that his label was addressed to medical men.

"Tempora mutantur, et nos mutamur in illis."

George Mee.

Apex.—Not unless the person's name is on either the Medical Register or the Register of Chemists and Druggists.

A. S. Thompson.—(1) Such registration cannot be effected under the present law, but is provided for in a Bill at present before Parliament. See before, p. 73. (2) There are three registered persons bearing the name.

W.—The Pharmacy Acts Amendment Bill has not yet been introduced into Parliament.

A. W. Turpin.—Our statement was quite correct; you will find the name in Gray's 'Supplement,' and other works. It no doubt originated in connection with a process formerly adopted in the manufacture of vermilion, or "factitious cinnabar," in which a regulus of antimony was used, although no antimony remained in the finished product.

Communications, Letters, etc., have been received from Messrs. Worrall, Hayes, Spencer, Thompson, Mackay, Heger, MacEwan, Bates, F. C. S.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from p.* 84.)

ÆTHER, U.S.P., P.G., and ÆTHER FORTIOR, U.S.P.—The "ether" of the U.S.P., as in the previous edition, contains more alcohol than that of the P.G. or B.P., it having a sp. gr. of about 0·750 at 15° C., and consisting of 74 per cent. of ethyl oxide and 26 per cent. of alcohol containing a little water. It should be neutral to test paper, and 10 c.c. shaken with an equal volume of glycerine should not be reduced to less than 75 c.c. The "æther" of the P.G. has a sp. gr. of 0·724 to 0·728, and boils at 34° to 36° C., and therefore, closely resembles the "æther fortior" of the U.S.P., the sp. gr. of which is fixed at not higher than 0·725 at 15° C., and the boiling point at 37° C. There is no representative of "æther purus," B.P. in either the U.S.P. or P.G.

ÆTHER ACETICUS, U.S.P. (new); P.G.—The acetic ether of the U.S.P. is described as having a sp. gr. of 0·889 to 0·897 and boiling at about 76° C. The P.G. gives the boiling point as between 74° to 76° and the sp. gr. at 0·900 to 0·904. The corrected B.P. sp. gr. is 0·900. These figures have recently been criticized by Dr. Clark (see *Pharm. Journ.*, [3], xiii., 782). Both the U.S.P. and P.G. require that when acetic ether is shaken up with an equal volume of water, the water shall not be augmented more than one-tenth of its original volume.

ALCOHOL and ALCOHOL DILUTUM, U.S.P., and SPIRITUS and SPIRITUS DILUTUM, P.G.—From the U.S.P., the "alcohol fortior," sp. gr. 0·817, has been omitted; but there has been a considerable increase in the strength of "alcohol," for whereas in the 1870 edition it was of sp. gr. 0·835, and was, therefore, intermediate between the P.G. "spiritus" and the B.P. "spiritus rectificatus," the U.S.P. sp. gr. is now ·820 at 60°F., representing 91 per cent. by weight of alcohol. The "spiritus," P.G., remains unchanged, sp. gr. 0·830 to 0·834, containing 87·2 to 85·6 per cent. by weight of spirit. The "alcohol dilutum" of the U.S.P. is made by mixing equal weights of alcohol and water, and is also stronger than in 1870, being sp. gr. 0·928 at 60° F., and containing 45·5 per cent. by weight of absolute alcohol. "Spiritus dilutum," P.G., is of sp. gr. 0·892 to 0·896, and contains 59·8 to 61·5 per cent. by weight of absolute alcohol. The respective specific gravities and percentage of alcohol in the two strengths of spirit in the three Pharmacopœias, are shown in the following table:—

U.S.P., 1880.		P.G., 1882.		B.P., 1867.	
Sp. gr. at 60° F.	P.c. by weight.	Sp. gr. at 59° F.	P.c. by weight.	Sp. gr. at 60° F.	P.c. by weight.
·820	91	·830–·834	87·2–85·6	·838	84
·928	45·5	·892–·896	59·8–61·5	·920	—

Alcohol Amylicum is omitted from the U.S.P.

SPIRITUS ÆTHERIS, U.S.P. (new); SPIRITUS ÆTHEREUS, P.G.—A "spirit of ether" has now been introduced into the U.S.P., it consists of 30 parts of ether and 70 of alcohol. The P.G. formula is 1 part of ether to 4 parts of spirit. The relative strength of the "spirit of ether" of the three Pharmacopœias, taking into account the characters of the ethers used, may therefore be represented as:—U.S.P., about 22 per cent. of ethyl oxide and spirit of sp. gr. 0·820; P.G., about 23½ per cent. of ethyl oxide and spirit of sp. gr. 0·830 to 0·834; and B.P., about 28 per cent. of ethyl oxide and spirit of sp. gr 0·838. The U.S.P. also includes a "Spiritus Ætheris Compositus: Hoffmann's Anodyne," made with stronger ether, 30 parts; alcohol, 67 parts; ethereal oil, 3 parts; which is, therefore, about the same ether strength as the "spirit of ether," B.P.

SPIRITUS ÆTHERIS NITROSI, U.S.P., P.G.—A considerable modification has been made in the U.S.P. formula for "spirit of nitrous ether," which in the 1870 edition closely resembled the B.P. formula. Seven parts of sulphuric acid (sp. gr. 1·840) are added gradually to 31 parts of alcohol (sp. gr. 0·820), the mixture when cooled transferred to "a tubulated retort connected with a well-cooled condenser, to which a receiver, surrounded by broken ice, is connected air-tight, and which is further connected, by means of a glass tube, with a small vial containing water, the end of the tube dipping into the latter." The nitric acid is added and heat is applied by means of a water-bath until strong reaction occurs and the temperature reaches 176° F.; the distillation is then continued at a temperature not exceeding 180° F. until the reaction ceases. The distillate is immediately poured into a flask containing 16 parts of ice-cold distilled water and the flask closed and shaken repeatedly, the temperature being kept down by immersing the flask occasionally in ice water. Finally the ethereal layer is separated and mixed with 19 parts of alcohol. No copper is used. The sp. gr. of the product is given as 0·823 to 0·825. Ten grams macerated with 1·5 gram of potassa for twelve hours, with occasional agitation, then diluted with an equal volume of water and after being set aside until the odour of alcohol has disappeared, acidulated with dilute sulphuric acid, should discharge the colour from a solution of 0·335 gram of permanganate of potassium, which is said to indicate the presence of at least 4 per cent. of real ethyl nitrite. The P.G. formula, which has not been altered, consists in distilling a mixture of 48 parts of spirit (sp. gr. ·830) and 12 of nitric acid (sp. gr. 1·185) until 40 parts have passed over, using enough magnesia to keep the distillate neutral, and at the end of twenty-four hours rectifying from a water-bath. The sp. gr. given is 0·840 to 0·850; it should form with water a clear solution, which treated with concentrated solution of ferric chloride should turn black. The P.G. orders the preparation to be kept over some crystals of potassium tartrate.

ALUMEN, U.S.P., P.G.—The U.S.P., 1870, included both ammonia and potash alum, but ammonia alum has now been omitted; the P.G. also orders potash alum.

ALUMEN EXSICCATUM, U.S.P.; ALUMEN USTUM, P.G.—The U.S.P. specifies that in preparing dried alum a temperature of 401° F. shall not be exceeded; the limit of temperature in the P.G. is 160° C. (320° F.). Both Pharmacopœias require that the product shall be slowly but completely soluble in cold water.

ALUMINII HYDRAS, U.S.P. (new).—Prepared by boiling together 11 parts of alum and 10 parts of sodium carbonate, each previously dissolved in 150 parts of water, and washing the precipitate with hot water until free from traces of sulphuric acid. Not in P.G. Both Pharmacopœias include sulphate of aluminium.

AMMONII BROMIDUM, U.S.P., P.G. (new).—Bromide of ammonium has been introduced into the P.G.

AMMONII IODIDUM, U.S.P.—This salt is now ordered not to be dispensed when "deeply coloured," but it is pointed out that it may be deprived of all but traces of free iodine by washing it with stronger ether and rapidly drying.

AMMONII PHOSPHAS has been on the one hand introduced into the U.S.P. and on the other hand dismissed from the P.G.

AMYL NITRIS, U.S.P. (new); AMYLIUM NITROSUM, P.G. (new).—In the U.S.P. the sp. gr. is given as 0·872 to 0·874, and the boiling point about 96° C. (205° F.). In the P.G. no sp. gr. is given, but its boiling point is fixed somewhat higher, namely, 97° to 99° C., the latter, according to Guthrie, being the boiling point of pure amyl nitrite. In both Pharmacopœias the limit of acidity is fixed by requiring that 10 c.c., after the addition of 2 c.c. of a mixture of 1 part of liq. ammoniæ and 9 parts of water, should not redden blue litmus. The U.S.P. gives as a test to distinguish nitrite from nitrate of amyl that when mixed with excess of solution of potash, a little test solution of potassium iodide added, and then acetic acid to an acid reaction, there is with the nitrite an immediate separation of iodine, giving the characteristic blue colour with gelatinized starch. It also requires that when exposed to the temperature of melting ice it should remain transparent, or nearly so, denoting the absence of water. The U.S.P. recommends that it be kept in small glass-stoppered vials, in a cool and dark place, and the P.G. says over some crystals of potassium tartrate.

APOMORPHINÆ HYDROCHLORAS, U.S.P. (new); APOMORPHINUM HYDROCHLORICUM, P.G. — This powerful derivative from morphia is introduced into both Pharmacopœias. The U.S.P. describes it, not very elegantly, as follows:—"Minute, colourless, or greyish-white shining crystals, turning greenish on exposure to light and air, odourless, having a bitter taste and a neutral or faintly acid reaction. Soluble in 6·8 parts of water and in 50 parts of alcohol at 15° C., slowly decomposed by boiling water or boiling alcohol, almost insoluble in ether or chloroform; should it impart colour to either of these liquids, it should be rejected, or it may be purified by thoroughly agitating it with either liquid, filtering, and then rapidly drying the salt on bibulous paper, in a dark place. The aqueous solution, on gentle warming, rapidly turns green, but retains a neutral reaction." The P.G. says: "Sal, si cum partibus centum Aquæ solutionem smaragdinam præbet, rejiciendum est." It also gives the maximum single dose as 0·01 gram, and the maximum daily dose as 0·05 gram.

ARGENTI CYANIDUM is retained in the U.S.P. as a means of preparing "dilute hydrocyanic acid" extemporaneously.

ARGENTI NITRAS DILUTUS, U.S.P. (new), ARGENTUM NITRICUM CUM KALIO NITRICO, P.G.—Under the former name a formula has been introduced into the U.S.P. for a variety of nitrate of silver pencils that has met with some acceptance. It consists in melting together in a porcelain crucible equal parts of nitrate of silver and nitrate of potassium, at as low a temperature as possible, stirring the melted mass until it flows freely and then pouring it into moulds. This and the next preparation are ordered to be kept in amber-coloured bottles. The P.G. "argentum nitricum cum kalio nitrico" is a similar preparation made with 1 part of nitrate of silver to 2 parts of nitrate of potassium.

ARGENTI NITRAS FUSUS, U.S.P. (altered).—this preparation now contains a little chloride of silver to give it toughness. It is made by melting 100 parts of nitrate of silver at a low temperature, then adding gradually 4 parts of hydrochloric acid, stirring until nitrous fumes cease to be evolved and pouring into moulds.

AURI ET SODI CHLORIDUM, U.S.P. (new); AURO-NATRIUM CHLORATUM, P.G.—This, according to the U.S.P., is an orange-yellow, slightly deliquescent, odourless powder, consisting of a mixture of equal parts of dry chloride of gold and chloride of sodium. No process is given in the U.S.P.; that in the P.G. consists in adding sodium chloride to a solution of gold in aqua regia and evaporating the liquid to dryness. It is used as a caustic and internally as a remedy in syphilitic disorders, the maximum single dose being given in the P.G. as 0·05 gram, the maximum daily dose as 0·2 gram.

ARGENTI IODIDUM, U.S.P. (new).—"A heavy, amorphous, light yellowish power, unaltered by light if pure, but generally becoming somewhat greenish-yellow, without odour and taste, and insoluble in water, alcohol, diluted acids or in solution of ammonium." Soluble in about 2500 parts of stronger water of ammonia. The salt fuses at about 720° F., and should be free from chloride.

BENZINUM, U.S.P. (new); BENZINUM PETROLEI, P.G. (new).—In the U.S.P. "benzin" (synn. "petroleum benzin" and "petroleum ether") is defined as a purified distillate from American petroleum, consisting of hydrocarbons chiefly of the marsh-gas series, having a sp. gr. from 0·670 to 0·675 and boiling at 50° to 60° C. The P.G. "petroleum benzin" consists of the colourless non-fluorescent portions of petroleum, having a sp. gr. of 0·640 to 0·670, and distilling nearly entirely between 55° and 75° C. It appears a pity that the names and synonyms adopted for this indefinite mixture should so closely resemble those of well-known definite substances; that some consequent confusion is anticipated is shown by the fact that both Pharmacopœias give a test for the absence of benzene.

BISMUTHI CITRAS, U.S.P. (new), and BISMUTHI ET AMMONII CITRAS, U.S.P. (new).—Bismuth citrate is introduced into the U.S.P. for the sake of the ammonia compound. It is ordered to be prepared by boiling 10 parts of bismuth subnitrate with 10 parts of citric acid in 40 parts of distilled water until a drop of the mixture gives a clear solution with ammonia water. The soluble citrate of bismuth and ammonium is prepared by making a paste of the citrate with double its weight of water, then adding ammonia water until the salt is dissolved, filtering, evaporating to a syrupy consistence, and scaling. The scales should be shining, pearly or translucent, neutral or faintly alkaline, very soluble in water and sparingly soluble in alcohol; but they alter by exposure, and are, therefore, ordered to be kept in small well-stopped bottles protected from light.

CAFFEINA, U.S.P. (new); CAFFEINUM, P.G.—This alkaloid has now been introduced into the U.S.P., where its solubility is given as 1 in 75 parts of water or 35 parts of alcohol at 15° C., 1 in 9·5 parts of boiling water, very soluble in boiling alcohol and 1 in 6 parts of chloroform. The above solubility in boiling water does not agree with a statement in the P.G. that the crystals "in pondere duplici aquæ fervidæ solvuntur, refrigeratæ in pultem crystallinam rigescunt." The P.G. also gives the solubility in chloroform at 1 in 9. Neither of the more soluble double salts of caffeine described by M. Tanret (*Pharm. Journ.*, [3], x.) has been adopted. The P.G. maximum single dose is 0·2 gram and the daily maximum dose is 0·6 gram.

Calcii Bromidum, U.S.P. (new).—This is described as a white granular salt, very deliquescent, odourless, having a pungent saline and bitter taste and a neutral reaction. It must not contain more than a trace of magnesium or of chloride, and no iodide or bromate.

Calx Sulphurata, U.S.P. (new).—Under this name is included in the U.S.P. the mixture usually know as "sulphide of calcium," but consisting chiefly of sulphide and sulphate of calcium in varying proportions. It is ordered to be made by submitting 100 parts of lime and 90 parts of precipitated sulphur in a luted crucible to a low red heat by means of a charcoal fire so arranged that the upper part of the crucible is heated first. When freshly prepared it is a greyish-white or yellowish powder, and it should contain at least 36 per cent. of real sulphide (CaS).

Camphora Monobromata, U.S.P. (new).—The body ($C_{10}H_{15}BrO$), which was discovered by Swarts about twenty years ago and introduced into medicine about ten years afterwards, has been made official in the U.S.P., but not in the P.G. It was also included in the new list of medicaments drawn up a few year since by the Paris Society, and will, therefore, probably find a place in the next edition of the Codex.

Carbonei Bisulphidum, U.S.P. (new).—It is described as boiling at 46° C. and having a sp. gr. of 1·272. Tests are given for its freedom from sulphurous and hydrosulphuric acids and sulphur.

Chinoidin, Cinchonidine Sulphate and Cinchonine will be referred to together with the other cinchona compounds.

Codeina, U.S.P. (new); P.G.—According to the U.S.P. codeine occurs in white or yellowish-white, more or less translucent rhombic prisms, but the P.G. now requires that the crystals shall be "coloris expertia vel alba," although in the 1872 edition they were allowed to be yellowish-white. The P.G. mentions that when boiled with water, before being dissolved, codeine liquefies and forms limpid drops that crystallize upon being cooled. The maximum single dose is given as 0·05 gram, and the daily dose as 0·2 gram.

Cupri Acetas, U.S.P.—The crystalline neutral acetate of copper takes the places of the subacetate in the U.S.P., whilst on the other hand it has been dismissed from the P.G.

Ferri Oxidum Hydratum c. Magnesia, U.S.P.; Antidotum Arsenici, P.G.—This antidote to arsenic is now included in the U.S.P. in addition to the hydrated oxide of iron. It is prepared from 1000 grains of solution of tersulphate of iron mixed with twice its weight of water, and 150 grains of magnesia rubbed to a thin paste with water and then transferred to a bottle of 32 ounces capacity which is then filled with water. The two liquids are kept separately until required and then the magnesia mixture is added gradually to the iron solution and the whole shaken together until a homogeneous mass results. It needs to be mentioned that the liquor ferri tersulphatis, U.S.P., is not so strong as the corresponding B.P. solution; its sp. gr. is 1·320 and it contains 28·7 per cent. of the salt. According to Hager (*Commentar*, i., 347) the freshly prepared antidote, well shaken, should be given in doses of one to two tablespoonfuls; at first every fifteen minutes, afterwards at half, one or two hour intervals. It is recommended in the U.S.P. to keep in separate bottles in like manner the ingredients for preparing hydrated oxide of iron until required for use.

Ferri Sulphas Præcipitatus, U.S.P. (new).—Same as granulated sulphate of iron, B.P.

Ferri Valerianas, U.S.P. (new).—This ferric salt is described as "a dark tile-red, amorphous powder, permanent in dry air, having a faint odour of valerianic acid and a mildly styptic taste. Insoluble in cold water, but readily soluble in alcohol. Boiling water decomposes it, setting free the valerianic acid and leaving ferric hydrate. . . . Mineral acids decompose the valerianate, forming the respective ferric salts and liberating valerianic acid." This salt has not been introduced into the P.G.

Ferrum Reductum.—The U.S.P. now specifies that with the iodine and iodide of potassium test reduced iron should give results corresponding to at least 80 per cent. of metallic iron, and the P.G. that it should require for its oxidation a quantity of potassium permanganate solution corresponding to at least 89·75 per cent. A few years ago eight specimens from English, French and German sources were examined by Mr. Creuse, who reported (*Pharm. Journ.*, [3], vi., 127) that the richest sample contained only 52 per cent. of metallic iron, while only one other contained more than 30 per cent.

Glycerinum.—In the U.S.P. the sp. gr. of glycerine has been maintained at not less than 1·250, which is the same as in the B.P. and corresponds to the presence of 5 per cent. of water. On the other hand, in the P.G. the sp. gr. has been lowered from 1·23 to 1·25 to 1·225 to 1·235, which would admit of the presence of at least 10 per cent. of water, on the ground that in practice it is preferable to employ a glycerine containing that amount of water. It has been pointed out that a preparation made with nearly anhydrous glycerine is capable of causing a smarting sensation and also that it absorbs moisture from the atmosphere. (See, for instance, *Pharm. Journ.*, [3], ix., 815).

Glycyrrhizinum Ammoniatum, U.S.P. (new).—The intensely sweet compound of glycyrrhizin with ammonia was first described by Roussin in 1875 (*Pharm. Journ.*, [3], vi., 53) and is said to represent the form in which glycyrrhizin exists in liquorice root. The U.S.P. directs it to be prepared by macerating 100 parts of liquorice root (No. 20 powder) during twenty-four hours with a mixture of 95 parts of water and 5 parts of solution of ammonia (sp. gr. 0·959), then percolating with water until 500 parts of percolate have been obtained, to which sulphuric acid is to be added as long as a precipitate is produced. This precipitate is collected, washed with cold water, redissolved in a mixture of water and ammonia, the liquid filtered if necessary, and then again precipitated with sulphuric acid. The precipitate is washed and dissolved in a sufficient quantity of solution of ammonia previously diluted with an equal volume of water, and the clear solution spread out to evaporate upon plates on glass. The product should be in dark brown or brownish-red scales, inodorous, of a very sweet taste, and soluble in water and in alcohol.

(*To be continued.*)

PSEUDO-GUTTA PERCHAS,*

OR SUBSTANCES SUPPLEMENTARY TO GUTTA PERCHA.

Foremost amongst pseudo-guttas, as we use the phrase, stands Balata gum. It is obtained from the *Mimusops Balata* of Gærtner (Nat. Ord. *Sapotaceæ*) and is synonymous with the *Sapota Mulleri* of Bleekrod, the *Achras Balata* of Aublet, etc. It is found in Demerara, Berbice, British and French Guiana, Antilles, Jamaica and Surinam. It has many vernacular names, amongst which may be mentioned, Balata, Paardenvleesch (Dutch—horse-flesh), bullet-tree, etc.

One of the first writers on this substance was Professor Bleekrod, who communicated some information as to the plant and its product to the Society of Arts, in 1857. He, too, described the plant and named it *Sapota Mulleri*. In 1860, Mr. Walker communicated samples, etc., received from Dr. Van Holst, of Berbice, to the same Society, and in 1864 Sir William Holmes also drew attention to the same subject. The tree is a large one with a trunk of about 6 feet in diameter, and furnishes a wood much liked for building purposes and of the colour of horse-flesh—hence the Dutch name. The bark is thick and rough, and the fruit is of the size of a coffee berry, sweet like a plum, and with a hard white kernel which yields a bitter oil. The leaves are glossy, oval and accuminated. The milk is drunk by the natives, in cases of diarrhœa, and when diluted with water it is used as cow's milk. The trees grow in groups and in alluvial soil.

The "Balata" gum is of a character somewhat between caoutchouc and gutta percha, combining in some degree the elasticity of the one with the ductility of the other, freely softening and becoming plastic and easily moulded like gutta percha. What small parcels arrived in England met with a ready sale and were remarkably free from adulteration. But, unfortunately, through the difficulty of collection—the undertaking being so dangerous and unhealthy—the supply of this excellent article has fallen off. It is collected by making incisions in the bark about 7 feet from the ground, and a ring of clay placed round the tree to catch the milk as it exudes. The yield is said to be in profusion especially at the time of the full moon, and the operation can be repeated every two months in the rainy season. It takes six hours to bring about coalescence by simple atmospheric influence, but very quickly by boiling in water. A large tree is said to yield as much as 45 lb. of "dry gum." The tree in every way is well worthy of a trial by acclimating it.

In India there are several plants whose products may be classed as pseudo guttas. First and foremost of these we have the Pauchontee or India gutta tree, the *Bassia elliptica* of Dalzell, the *Isonandra acuminata* of Lindley, but now known as *Dichopsis elliptica*. It is found in the Wynaad, Coorg, Anamallay and Neilgherry Hills, Sholah Forest, Cochin, Sichar, and according to General Cullen, "appears to be common in all the forest tracts at all within the influences of the south-west rains." This tree, which is now placed in the same genus as the true gutta percha, is a large one—from 80 to 100 feet high—and was first met with by Mr. Dalzell, in North Canara, near the falls of Goirsuppah, in 1849. Since that date, General Cullen and Dr. Cleghorn have used every exertion to bring the substance prominently forward, but without success. The gum is obtained by tapping, $1\frac{1}{2}$ lb. being obtained from one tree by five or six incisions, a large tree yielding as much as 20 to 40 lb. of sap. Many experiments have been made with specimens of the raw milk, *i.e.*, milk simply dried by exposure to the atmosphere. The results of these experiments have shown that for telegraphic purposes it is wanting in some essential qualities, but it has been recommended as a subaqueous cement or glue. When dissolved in ordinary gutta percha solvents, it, after the evaporation of the solvent, remains some time soft and viscid, and partakes somewhat of the character of bird-lime. When cold, it is hard and brittle. Without wishing in the slightest degree to throw doubt or discredit on the many and valuable experiments made, we would suggest that good samples be collected and treated in the same manner as recommended for gutta percha. We have no doubt that many a parcel of what would otherwise be *good* gutta percha, is spoilt through not being well boiled *immediately* after collection from the tree. At present this is the only way in which we see there is a possibility of ascertaining whether this product can be utilized, and we have the more hope from the fact that the structural character has led the plant to be placed in the same genus as the true gutta percha—structural affinity agreeing so often to chemical affinity.

There are in India other nearly allied *Sapotaceæ* which deserve attention in order to ascertain whether any of them yield a milky juice likely to be of commercial use. Amongst the *Euphorbiaceæ* there are two plants worthy of notice. The *Euphorbia Cattimandoo*, found in various parts of India, was first brought to notice by the Honourable W. Elliot, and a prize medal was awarded for this substance by the jurors of the 1851 exhibition. This spiny euphorb grows to the size of a shrub or small tree, and the milk flows out freely when a branch is cut. The natives use it as a cement to fasten knives in handles, etc. Under the influence of heat it becomes soft and viscid, and when dry, very brittle. The *Euphorbia Tirucalli*, the milk hedge or Indian tree spurge, is a succulent unarmed plant attaining a height of 20 feet, and its inspissated milk is used for various—chiefly medicinal—purposes, and has been recommended as a gutta percha substitute; but like gum *Euphorbium*, it has a very acrid character, and the collection is a very dangerous operation to the eyes.

* From the *Indian Agriculturist*. Reprinted from the *Tropical Agriculturist*.

THE RAPID DETERMINATION OF THE VALUE OF EXTRACT OF MALT.*

BY J. F. CARL JUNGK.

It is customary to consider an extract of malt good, if it readily dissolves in water, has a pleasant taste and also remains unfermented for a long time. Worthless preparations may have all these properties, therefore such an examination is only superficial. Thus far no convenient process has been published by which the pharmacist or physician may convince himself of the value of extract of malt. Such a process, in daily use by me, may, therefore, be of interest. A good extract of malt should, I think, possess the following properties in addition to those noted above.

I. The extract should be light in colour; dark coloured preparations are partly burned, therefore contain neither active diastase nor soluble albumen, and differ from ordinary molasses only in containing dextrin.

II. The free acid should not be present over a certain proportion.

III. The proportion of water and solid matters should be within certain limits.

IV. The principal determination is that of the diastastic strength. A good extract should contain all soluble substances of the malt, of which diastase is the principal one. If the extract contains no diastase it differs little from honey or any other saccharine preparation. The action of diastase on amylaceous substances is wanted if the extract is to possess any value for a sick stomach at all.

Liebig uses powdered malt in preparing his infants' food, in order to change the starchy matter, before it enters the stomach, into easily digestible compounds. If we consider how much amylaceous food we use which could be changed by a small quantity of diastastic extract

* From the *American Journal of Pharmacy* for June.

of malt into dextrin and sugar, the value of such a preparation in the process of digestion is readily seen. Although the saliva possesses the same properties as the diastase of the malt, the action of the latter is nearly five times as great as that of the former, and the diastastic action of the malt can stand about four times more acid than that of the saliva without being interfered with.

V. Nitrogenized constituents (albuminates) should be present in an easily digestible form.

These are the principal conditions in the analysis of an extract of malt.

Many put a great value on the soluble phosphates in the examination of the ash, but it cannot be accepted as a criterion of a good extract. The percentage of the phosphates will vary according as hard or soft water is used, and furthermore, these substances can be added to the most worthless preparation. The examination of the ash will not be described here, as directions can be found in every analytical work.

The estimation of the percentage of dextrin and maltose is also of no consequence, as a preparation which has the properties noted above will have the proper amount of dextrin and sugar.

Estimation of Solid Matters and Water.—Twenty grams of extract are dissolved in enough distilled water to make the solution weigh 200 grams. With this solution I determine the percentage of extract by means of a Czeczetka's maltometer, which shows the percentage of extract dried at 110° C. Those not in possession of one or of a similar instrument should estimate the specific gravity of the liquid at 17·5° C., and compare the same with a table by Griesmayer, published in 'Fresenius' Analytische Zeitschrift,' 1880, page 104, in order to determine the amount of extract. Another method is the following:—

Specific gravity.	Extract dried at 100° C.
1·1032	50 per cent.
1·1053	51 per cent.
1·1075	52 per cent.
1·1096	53 per cent.
1·1117	54 per cent.
1·1138	55 per cent.
1·1159	56 per cent.
1·1180	57 per cent.
1·1202	58 per cent.
1·1235	59 per cent.
1·1258	60 per cent.
1·1281	61 per cent.
1·1305	62 per cent.
1·1329	63 per cent.
1·1353	64 per cent.
1·1377	65 per cent.
1·1401	66 per cent.
1·1425	67 per cent.
1·1449	68 per cent.
1·1473	69 per cent.
1·1497	70 per cent.
1·1521	71 per cent.
1·1545	72 per cent.
1·1569	73 per cent.
1·1594	74 per cent.
1·1618	75 per cent.
1·1668	77 per cent.
1·1691	78 per cent.
1·1718	79 per cent.
1·1741	80 per cent.
1·1767	81 per cent.
1·1792	82 per cent.
1·1818	83 per cent.
1·1844	84 per cent.
1·1870	85 per cent.
1·1897	86 per cent.
1·1925	87 per cent.
1·1952	88 per cent.
1·1979	89 per cent.
1·2007	90 per cent.

A certain weight of extract is dissolved in an equal weight of water, the specific gravity of this solution at 17·5° C. is determined and from the table given the percentage of extract is ascertained. On subtracting the extract from 100 the percentage of water is found.

A good extract containing both diastase and albumen seldom contains more than 25 per cent. of water. Should the percentage of extract fall to 50 or, as with many so-called beers, to 5 or 6 per cent., diastase cannot be present, as it would not keep in such diluted liquids. To such preparations salicylic acid is usually added to prevent for some time the decomposition of the dextrin. On agitating such a preparation with strong ether, the salicylic acid is easily separated. Evaporate the ethereal solution, dissolve the residue in water and test this solution with diluted ferric chloride, when the salicylic acid is easily recognized by the violet colour produced. If we reflect that the addition of one-fourth to one-half per cent. of salicylic acid to solutions of starch renders even preparations very rich in diastase inactive, it becomes obvious that the addition of this acid to an extract of malt is incorrect.

Determination of Free Acid.—The free acid of freshly prepared extract of malt is almost exclusively lactic acid; but with the age of the preparation other acids are formed, and for this reason I estimate the amount of caustic soda used and note this as percentage. In a solution of pure caustic soda, 5 grams to 1000 c.c. water, each c.c. represents 0·005 sodium hydrate. Ten grams of extract are dissolved in 100 grams of water and neutralized with the soda solution. For this purpose a burette graduated into one-tenth c.c. is used, and the point of neutralization determined by means of very sensitive litmus paper. With a little practice the estimation of the acid does not present any difficulty. Good extract of malt tested by this method will seldom require more than 6 to 7 c.c. soda solution.

To take an example, suppose 6 c.c. soda solution, that is, $6 \times 0·005 = 0·030$ hydrate of sodium, to be necessary for complete neutralization of 10 grams of extract of malt, then 100 grams of extract must need 0·30 sodium hydrate. If for 100 parts of extract of malt more than 0·5 sodium hydrate should be required, the durability of the preparation will be doubtful and the diastatic power will soon disappear.

Estimation of Diastatic Strength.—Twelve clear and uniform 2 oz. vials each filled with 2 oz. distilled water and 2 drops of iodine solution, prepared from 2 grams iodine, 4 grams iodide of potassium and 250 grams water; a good thermometer and starch mucilage are needed for this purpose.

Ten grams of starch are stirred with 30 grams of water and poured into 125 or 150 grams of boiling water. The mixture is stirred and boiled for some time. The thermometer is then introduced and the mucilage is allowed to cool to and kept at a temperature of 100° F. by means of a water-bath.

Ten grams extract of malt dissolved in 10 c.c. water are then stirred into the mucilage, the time being accurately noted. After one minute a good extract will have converted the thick mucilage into a thin liquid. As soon as this change has taken place it is necessary to examine the progress of the conversion of starch into soluble starch, dextrin and sugar at the end of every minute, by the following method:—

After the expiration of the first minute transfer two drops, by means of a glass rod, into one of the 2 oz. bottles. The bottle is shaken and placed near a window. At the end of every minute repeat this manipulation with a new bottle until the coloration is no longer produced. The time necessary for effecting this change gives the indication as to the amount of diastase present. Undecomposed starch mucilage gives a greenish blue colour and after standing some time a blue precipitate. Soluble starch, the first product of the change, yields with iodine, a dark blue solution without a precipitate.

If the amount of soluble starch equals that of dextrin and sugar the colour of the solution will be purple. As the soluble starch disappears the solution will be of a decided red colour if dextrin predominates, or faintly red if the sugar be in excess; and when starch and most of the dextrin have been converted into sugar, the liquid will be nearly or entirely colourless. This experiment is very interesting and is simple to perform.

A good extract of malt should convert its own weight of starch within ten minutes at 100° F.; at 62° F. forty minutes will be necessary for the conversion, and at 150° F. only three minutes. An extract of malt of the above strength will convert five times its weight of starch at 100° F. in forty minutes and eight times that amount in ninety minutes.

Furthermore, an extract of malt which converts its own weight of starch at 100° F. in ten minutes into dextrin and sugar will in the following time digest the following boiled amylaceous articles:—

Boiled potatoes, 4 parts in three minutes; 16 parts in fifteen minutes.

Boiled rice, 4 parts in ten minutes.

Boiled bread, 4 parts in nine minutes; 16 parts in forty-five minutes.

Boiled crackers, 4 parts in five minutes; 16 parts in twenty-five minutes.

Boiled sago, 4 parts in twelve minutes; 8 parts in thirty minutes.

The following experiments made with the view of studying the influence of acids and alcohol on diastase and the conversion of starch are produced in tabular form in comparison with saliva. They may interest many readers, and encourage them to similar investigations.

The experiments were conducted as follows:—

1. A paste was made by boiling starch in water until it was thoroughly gelatinous, 5 fluid ounces containing exactly 100 grains of starch; the specific gravity of this paste was 1·0117.

2. For each experiment, 5 fluid ounces of the paste were mixed in a porcelain capsule with 200 minims of a mixture of equal parts of malt extract and water. The malt solution was freshly prepared each day from the same sample of malt extract, and tested, to secure a uniformity of *diastatic power*. In the experiments with saliva, 100 minims were added to the 5 fluid ounces of starch paste. The saliva was collected from a number of persons, both adults and children, and was tested from time to time. The saliva always gave a neutral reaction, while the malt extract always gave an acid reaction, owing to the presence in the latter of $\frac{4}{10}$ per cent. of acid calculated as lactic acid.

3. Before adding the malt extract solution or saliva, the starch paste was by means of a water-bath brought to a temperature of 100° F., and maintained at a temperature ranging from 95° to 100° F. until the experiments were completed.

4. The acids or alkalies were always added to and thoroughly mixed with the paste before adding the malt extract solution or saliva.

5. When the change in the condition of starch paste operated on was very rapid, it was tested every minute with iodine, otherwise every five minutes. In a few instances the action was so rapid that tests were required to be made in fractions of a minute.

6. The iodine solution was made and used as described above.

7. Except in a few instances, the experiments were discontinued at the end of an hour.

8. The acids were calculated as anhydrous.

Malt	$1\frac{1}{2}$	21·7*	3·2	3·2	—	1	2	3	5

* Starch precipitated.

The last table shows that the diastatic action of extract of malt and of saliva is but little affected by the presence of alcohol in the starch solution, but is influenced by the acid. The small amount of sulphuric acid contained in the wine interferes little with the action of malt extract compared with that of saliva.

DETERMINATION OF THE NITROGENIZED BODIES.

Albuminates.—For this estimation I use a solution of picric acid in water, saturated in the cold; also a glass tube such as is used for the estimation of nitrogen in elementary analyses, divided into one hundred equal parts, the lower five divisions being further divided into fifths; but any tall narrow glass cylinder, which is divided accurately into equal parts, will answer the purpose. The cylinder is filled with eighty parts of the solution of picric acid, and twenty parts of extract of malt, and well agitated until the extract is dissolved with the exception of the albumen, then placed in a vertical position for twenty-four hours and the quantity of precipitate read off. Each division represents 1 per cent. by weight of albumen (nitrogenous matter) dried at 100° C.

The correctness of this estimation is reliable within $\frac{1}{5}$ per cent. and has been verified by a series of elementary analyses, undertaken with the view of convincing myself of the exactness of this method, which may be approximately proven by coagulating the albumen by boiling. This last method is never exact, since malt contains some nitrogenous matter which is not coagulated by heat.

The average amount of nitrogenous matter contained in extract of malt of the consistency of honey is 3 to 3·25 per cent. A well prepared extract of malt produces, with cold water, a faintly turbid solution, which becomes much clearer if carefully heated to 150° F.

The above described determinations with extract of malt furnish the proof as to whether the preparation is of good quality or is worthless.

Simple Estimation of Dextrin, Sugar and Glycerin.—A polariscope is not always available, and if at hand the instrument must first be tested with pure crystallized malt sugar; the separation of the sugar from dextrin, and the decolorization of the liquid are tedious operations. For these reasons I use this method only occasionally for controlling the results; but the following short process will be found to give quite accurate results.

Weigh from 2 to 5 grams of extract of malt; mix with 20 grams of dry sand which has been previously washed with hydrochloric acid and water, and dry this mixture in an air-bath at 100° C. until it ceases to lose weight. The loss of weight represents amount of water.

Transfer the mixture into a small glass percolator (glass syringe) supported by a wire stand of such a size that the entire apparatus may be weighed on an analytical balance. Dry thoroughly in an air-bath and weigh. Now percolate with strong ether, evaporate the percolate and dry the residue; its weight indicates the *resin of hops.* The apparatus is also dried in the air-bath and weighed; the loss in weight shows likewise the resin of hops.

Then percolate with a mixture of two volumes of absolute alcohol and three volumes concentrated ether until a drop of the percolate heated on a platinum foil will not char. The loss of weight after drying in air-bath represents *glycerin.* A mixture of chloroform and alcohol cannot be used as a solvent for glycerin, as the malt sugar is somewhat soluble therein.

Exhaust the residue completely with stronger alcohol; dry and weigh. The loss of weight gives amount of *sugar.*

The balance, after subtracting the weight of sand is *dextrin* and *albumin.* The dextrin may also be extracted with hot water and determined from the loss of weight.

After igniting the sand its weight must be the same as in the beginning. The difference in weight before and after ignition indicates the weight of albumen.

By the methods detailed above I have examined twenty different malt extracts of American and European manufacture; but the publication of the figures obtained would be of no value unless accompanied by the designation of the articles, which appears to be inadmissible.

THE SPONGE TRADE OF THE BAHAMAS.*

Next to the pine-apple business the sponge trade is the most important industry of the Bahamas, bringing considerable money into the colony, and furnishing steady and lucrative employment to several hundred vessels and several thousand persons.

Forty years ago the gathering and shipment of sponges was practically unknown in these islands. The people found so much more profit and excitement in the business of "wrecking" that the ordinary methods of procuring a livelihood were not in much favour.

Gradually, however, as the erection of lighthouses upon exposed points and the substitution of steam for sailing craft lessened the number of wrecks, the colonists began to cultivate the soil and to explore the depths of the sea in the pursuit of wealth.

At first sponges were divided into only two classes, the coarse and the fine, the former bringing about 5 dollars per cwt., and the latter about double that sum. Sponges are now divided into many varieties, the principal of which known to the trade here are as follows, in the order of their value, the first being the best, viz.:—Sheep-wool, white reef, abaco velvet, dark reef, boat, hard-head, grass, yellow, and glove. Of some of these varieties there are several grades designated by numbers, all being useful for mechanical, surgical, and bathing purposes. Bahama and Florida sponges are of about equal value, both kinds being inferior in texture and market value to those of the Mediterranean.

From the opening of the trade in the Bahamas up to the year 1864 the amount of sponges gathered was small, averaging only 3331 pounds per annum, valued at 26 dollars per cwt. During 1863–65 the business of blockade-running so engrossed the Bahamians that nearly all legitimate business was suspended, and the sponge industry sank to a low ebb. In the years immediately subsequent to our civil war the trade grew brisker until the outbreak of domestic troubles on the adjacent island of Cuba gave it a check, the Spanish authorities withdrawing the privilege of fishing for sponges upon the Cuban coast, lest the spongers might carry on a contraband trade with the insurgents. In 1878, the insurrection having been substantially quelled, the Spanish consul at Nassau issued over one hundred licences, at 25 dollars apiece, to Bahamian vessels to sponge in Cuban waters, and the trade was rapidly reviving when the jealousy of the Spaniards was aroused, and all the licences were peremptorily revoked. Since then the Bahama spongers have confined operations to their own waters, but with such assiduity that new fields have been discovered, and the yield has materially increased.

The vessels employed in sponging are small craft, their average being about ten tons burden, each vessel carrying from six to twelve men. These vessels take on board about six weeks' provisions and start out coasting along the banks and reefs, where the water is shallow, and among the islands, for in such localities the sponges are found. In case of a storm the little craft takes refuge inside the coral reefs or under the lee of an island. The sponges are readily seen growing upon the rocks reefs and shallows, for the water is marvellously clear, and they are brought to the surface by means of iron

* From a Report by Consul McLain of Nassau. Reprinted from the *Canadian Pharmaceutical Journal*, July.

hooks fastened to long poles, or by diving. When first caught they are found to be covered with a soft gelatinous substance, full of life, and as black as tar, the sponge proper being really only the skeleton or the support of this living organism.

The day's catch is spread upon the deck so as to kill this living covering, which in decaying emits an odour by no means as fragrant as that of frangipanni. When a sufficient quantity of sponge has been gathered to warrant it the spongers go ashore, build a pen or "crawl" of stakes at the water's edge, and place the sponges therein, when the action of the tide helps to remove the black covering, the process being completed by pounding the sponges with sticks. Having been cleansed in this manner the sponges are strung upon small palmetto strips, each string containing three or four sponges, being called a "bead," and with this cargo the vessels return to Nassau. A cargo will range in value from 75 dollars to 300 dollars, according to quality, quantity and demand.

The sales and handling of sponges are substantially controlled by what is known as the "Nassau Sponge Exchange Company, Limited," an organization holding a charter from the colonial Legislature, with a capital of £600, and possessing certain privileges. The company has erected a commodious building upon one of the wharves, and here all the sponges are sold, subject to certain taxes and restrictions. No person is permitted to buy until he has become a member of the exchange, under certain conditions, and a seller who attempts to dispose of his cargo outside of the exchange will soon be put under the ban. Sales are made upon every week day, except Saturday, at 11 o'clock a.m., each buyer offering his tender in writing and privately, and he is expected to make some offer for each lot on sale.

As soon as the daily sale is concluded, the sponges are hauled away to the packing yards, where they are assorted and clipped into good shape. They are then put into tubs or vats of lime-water to soak for several hours, and are afterwards spread upon canvas to bleach and dry in the sun. Next they are pressed by machinery into bales about 3 by 2 feet in size, each containing 100 pounds, the packages being covered with coarse bagging securely sewed and corded, and are then ready for shipment. All the work bestowed upon the sponges from catching to shipment, except the purchasing at the exchange, is performed by the native blacks.

There are at present only about a dozen qualified buyers of sponges in Nassau, nearly all of whom buy exclusively for houses in America and England.

The American trade is monopolized by a few firms in New York (through resident agents in Nassau), the leading houses being as follows, viz.:—Messrs. A. Isaacs and Co., Mansell, Birnbaum and Co., Raboteau and Moses, Lasker and Bernstein, McKesson and Robbins, and Wrightington and Jackson.

The average current market value of sponges in this colony for the past year or two is substantially as follows, which represents their cost on shipboard, viz.;—Sheep-wool, 75 cents per pound; white reef, 75 cents; abaco velvet, 55 cents; dark reef, 35 cents; boat, 35 cents; hardhead, 30 cents; grass, 20 cents; yellow, 20 cents; glove, 15 cents. These are for the best grades of each variety, and are the average of prices; the absolute prices, of course, changing at times, according to the laws of trade.

Bahama sponges are shipped to the United States and Great Britain, with an occasional lot to Paris. Up to three years ago, Great Britain got the bulk of the trade. Since then the United States has taken a greater part of the sponges. In 1881 the total value of the sponges shipped from these islands was 150,000 dollars, of which 36,357 dollars worth went to England, and 113,643 dollars went to the United States. The following figures will show the volume and course of the sponge trade of the Bahamas for the last eight years:—

Year.	Exports to Great Britain. Dollars.	Exports to United States. Dollars.	Total. Dollars.
1874	32,500	44,000	76,500
1875	42,600	34,400	77,000
1876	52,000	35,000	87,000
1877	59,300	30,700	90,000
1878	69,927	53,073	123,000
1879	95,000	70,000	165,000
1880	66,000	102,428	168,000
1881	36,357	113,643	150,000
1882 (first quarter only) . .	...	82,664	...

As appears above, the first quarter of the present year shows a signal increase in the trade with the United States, the amount shipped during January, February and March being more than two-thirds as much as the total for the year 1881, which year was itself an improvement over all the preceding ones.

There was no special increase during that quarter in the shipments to Europe. This sudden increase in shipments to the United States was owing to the discovery of a new and extensive field of sponges near the island of Elouthera, only sixty miles distant from Nassau, the product of which the American agents eagerly bought up.

The water on the new field is from five to eight fathoms in depth, making the gathering of the sponges tedious and laborious. It is thought that the field is a very extensive one, extending over many miles, and the sponges are, so far as known, all of the sheep-wool or most valuable variety.

The majority of the sponges found up to this time are of an extra large size, and they will not bear cutting to advantage, since the inner portions seem to be very tender. A medium sized and solid sponge would have been more valuable.

During the last quarter this field was actively worked, but a sudden interruption has occurred, caused by the fact that myriads of small fish called "sailors" have invaded the grassy bottom, stirring up the mud to such a degree as to prevent the sponges from being seen. Old fishermen give it as their opinion that the sponges can be gathered to advantage in this field only during a portion of the year, when the water is still and the "sailors" are absent. If this be true, it will detract somewhat from the value of the new find.

If the colonists could handle and ship the sponges on their own account, as they do with their pine-apple crop, the trade would be of more benefit to the islands; but their control ceases when the sponges are sold at the exchange, and all subsequent profits after shipment go to the foreign purchaser.

The business of gathering, curing, and packing, however, brings about 150,000 dollars of foreign capital into the colony every year, which is largely sent to the United States to purchase materials for the vessels, provisions for the men, and for general purchases; and so any increase of the sponge industry will enlarge the amount of goods which the colonists will be able to buy of us. In fact, the trade relations of the Bahamas are now so intimate with the United States, that the prosperity of the former is directly beneficial to the latter; and we do not overstate the truth when we assert that this colony, although politically a "dependency" of Great Britain, is in reality, so far as an increasing profitable trade and commerce is concerned, a "dependency" of the United States. A liberal spirit on the part of our Government, and fair and honest dealing by our merchants and manufacturers, are all that is needed to retain our present trade with the Bahamas, and to materially enlarge the same, as the colony itself develops its natural resources and prospers.

THE RELATION BETWEEN FLUORESCENCE AND CHEMICAL CONSTITUTION OF ORGANIC BODIES.*

Why do some substances exhibit fluorescence and others not? This is a problem that must remain for a long time unsolved, and we cannot, at present, expect to answer that question any more than we can tell why sodium sulphate is soluble in water while barium sulphate is not.

In order to approach a little nearer to an understanding of the subject, we must decide to proceed in such a way as to find out what may be called the *statistical* reason, as distinguished from the true and actual cause. This can be accomplished by grouping together known facts and cases so as to see what peculiarities of constitution are common to substances having the same physical peculiarities. This method has been pursued in the numerous experiments made to determine the cause of colours in dyes, and it can also be applied to the study of fluorescent bodies, of which there are already quite a large number to experiment upon.

Liebermann collected the fluorescent derivatives of anthracene, and thereby arrived at a very remarkable result. Anthracene has the formula $C_6H_4(CH)_2C_6H_4$, or two groups of C_6H_4 are connected by a pair of carbon atoms, to each of which is attached one of hydrogen; hence these hydrogen atoms (which we have placed in the parenthesis) have an entirely different position from the others. Liebermann found that all anthracene derivatives which contained these hydrogen atoms unchanged, or had them replaced by monad groups, possessed fluorescence. If, however, the CH groups are changed to CO groups, as in anthraquinone, which has the formula $C_6H_4(CO)_2C_6H_4$, and its derivatives, the fluorescence is wanting.

The most beautiful and intense exhibition of fluorescence is shown in a substance discovered by Baeyer, and called "fluoresceine." It is made from resorcine, $C_6H_4(OH)_2$, and phthalic acid, $C_6H_4(COOH)$, by fusing them together. The new compound may be looked upon as resorcine, in which one of the hydrogen atoms of the C_6H_4 group has been replaced by the residue of the phthalic acid. For brevity we may represent this residue by *Phth*, and write the formula of fluoresceine thus: $C_6H_3(Phth)(OH)_2$. It is a brick red powder, and when dissolved in alkalies forms a red liquid which has such an intensely green fluorescence that, viewed by reflected light, one thinks that he sees a glittering green precipitate in the liquid, which was clear by reflected light and of a red colour. This peculiarity enables us to utilize the phthalic acid as a delicate reagent for the detection of resorcine. If the slightest trace of the latter is melted with phthalic acid, and the fusion dissolved in alkali, the liquid will exhibit this magnificent fluorescence in the most intense degree.

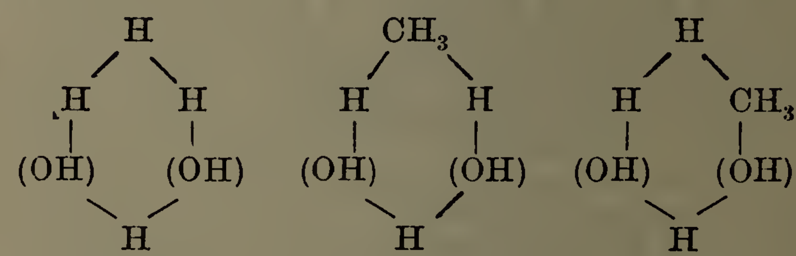
Orcine is a homologue of resorcine. In constitution it is a resorcine with the hydrogen atom replaced by the methyl group, CH_3, a methylated resorcine having a formula $C_6H_3,CH_3,(OH)_2$. This substance is very similar to resorcine in all its properties and reactions, except in its action towards phthalic acid. It does, indeed, unite with the latter, but the resulting compound has no fluorescence at all. In a free state it is colourless, and its alkaline solution is red both in transmitted and in reflected light.

To ascertain why it was that a substance so similiar to resorcine should act so differently in that one respect, Knecht adopted an ingenious method of experimentation. He prepared a substance homologous with resorcine, but having the same chemical composition as orcine, a new isomeric body. This substance, which he called *cressorcine*, has the formula $C_6H_3,CH_3(OH)_2$. It was made from cressol, or methyl phenol, the constitution of which is well known.

Cressorcine, this new isomer of orcine, was found to yield a fluorescent body when melted with phthalic acid, although the new substance had the same chemical composition as the colourless one obtained from orcine and phthalic acid.

The fluoresceine prepared from cressorcine is so similar to that obtained from resorcine that Knecht sought for a long time before he could discover any method of distinguishing the one from the other. Both are brick red powders, soluble in alkali with an astonishing green fluorescence, but by the action of acetic anhydride, acetyl ethers of unlike melting points are produced.

The theory proposed to account for this is that in orcine the CH_3 group occupies the position usually designated as No. 1, and that when this is left free the phthalic acid attaches itself there to form fluoresceine, but that is not possible when this is occupied, as it is in orcine, by a methyl group. The following diagrams exhibit the relative position of the groups on Kekulé's benzol ring:



Resorcine. Orcine. Cressorcine.

HEDGE-MUSTARD OIL.*

BY E. VALENTA.

To obtain a substitute for rape-seed oil there has been an oil manufactured of late years from the so called hedge-mustard or bank-cresses—*Raphanus raphanistrum* or *Raphanistrum arvense*, a plant which is now cultivated in Hungary. This oil is brought to the market either by itself or mixed with rape-seed oil and under this latter name.

The siliquous fruit of the plant mentioned bears little seeds which contain 30 to 35 per cent. oil. This can be for the most part obtained by pressing. It has a dark olive-green colour, and an odour and taste very similar to rape-seed oil; its density and faculty for saponifying with alkali is also nearly the same, so that it is difficult to recognize it in a mixture of the two oils. The author, who has made this point the object of a special examination, has tested the two oils as regards their behaviour to the usual reagents.

On acting upon them with acids of different strength, such as sulphuric and nitric acids, a mixture of these, aqua regia, phosphoric acid, etc., as well as with oxidizing mixtures, as potassium bichromate and sulphuric acid, or concentrated nitric acid saturated with nitric oxide, various colours are produced with both oils, by the shade and intensity of which they can be pretty well distinguished.

The author gives a list of these reactions. Most characteristic for hedge-mustard oil appears the following reaction:—About 5 grams of this oil are saponified with potassium hydrate and spirit with warming, and the soap thus obtained is filtered from the unchanged oil, which is golden yellow and almost odourless and tasteless. The concentrated filtrate, on adding hydrochloric acid to strongly acid reaction, assumes a distinct green colour if a somewhat large portion of hedge-mustard oil be present.

WHAT IS THE SOURCE OF LEDGER BARK?

AT a meeting of the Linnean Society, on May 3, a paper on this subject was read by Mr. J. E. HOWARD, F.R.S., the substance of which we had intended to lay before our readers as soon as the paper should be published in the Journal of that Society. A report of Mr. HOWARD'S paper has, however, in the meantime reached the Colonies and has provoked a somewhat animated discussion, as a result of which Mr. T. N. CHRISTIE, one of the leading cinchona planters of Ceylon, has forwarded to us samples and notes which he hopes may clear up the points in dispute.

The point at issue appears to be whether the plant named "*Cinchona Ledgeriana*" by Dr. TRIMEN is a true species or only a variety of *Cinchona Calisaya*. Mr. HOWARD published in his 'Quinology of the East Indian Plantations' a description by Dr. WEDDELL of a variety of *Cinchona Calisaya*, which he named *Ledgeriana*. Of this plant three plates were figured, all of which were drawn from plants grown from seed bought of Mr. LEDGER in 1868, and cultivated in Java.

In November 1881, Dr. TRIMEN, who had then seen, in a growing state, the "Ledgeriana" trees as known to planters in Ceylon, and as recognized by Mr. MOENS of Java, described the Ledgeriana tree as a distinct species, in the *London Journal of Botany* for that month, giving the features which he considered distinctive, and a full description of every part of the plant as well as a figure of the leaves, flowers and fruits. To this description of the Ledgeriana plant, as a good species, Mr. J. E. HOWARD appears to have taken exception in the paper read before the Linnean Society, and so far as we understand the remarks made, or reported to have been made, by him, he believes "the tree "figured as *C. Ledgeriana*, Moens, to be no Calisaya at "all, but a species, standing intermediate between *C.* "*Calisaya* and *C. micrantha*, or a mere variety of "*C. micrantha*," probably var. *Calisayoides*, and he thinks "it will be evident to any botanist" that the plates as well as the descriptions differ very widely. But it is a further question whether the plant thus referred to is that described in WEDDELL'S Notes (Translation, p. 40). Mr. HOWARD adds, "On Mr. MOENS' own authority, I claim that mine alone are authentic," and he seems further to have stigmatized Dr TRIMEN'S typical plant as derived apparently from seed of uncertain origin, given by Mr. MCIVOR.

The question therefore arises, what is the true Ledger Cinchona? Dr. TRIMEN says that the seed from which his plant was raised came from the late Mr. MCIVOR, and that there can be no doubt it was obtained from trees which originated from Mr. LEDGER'S seed. Mr. HOWARD states that his figures were drawn from trees grown in Java from LEDGER'S seed. His description of *Ledgeriana* is not so full as Dr. TRIMEN'S, and the points which Dr. TRIMEN mentions as characteristic of the tree do not appear in Mr. HOWARD'S statements. The features mentioned by Dr. TRIMEN as characteristic are as follows: Leaves always having the broadest part at or about the middle, flowers drooping or divaricate, flower-buds not at all or very slightly widened at the end and never abruptly enlarged there, corolla somewhat inflated in the middle. The unexpanded leaves and the buds and young soft shoots have a bronzed or olive-orange tint, by which, in a field of Calisaya, the plants of *Ledgeriana* may often be picked out at first sight. We have here, therefore, definite characters by which two excellent botanists as well as the planters in Ceylon distinguish a distinct form or variety or species, whichever it may be, for it can only be proved to be a distinct species by it coming true from seed. Dr. TRIMEN admits (*Journ. Bot.*, 1881, p. 322) that we have at present little direct evidence to show that the plant does come true from seed. He also remarks that the progeny which comes from any sowing of *C. Calisaya* seed are certainly less like one another than some are like *C. Ledgeriana*; moreover, seed from the latter has not hitherto been found to come very true, even the progeny of the original seed from Bolivia showing a good deal of variation. The theory that this is due in some measure to "cross-fertilization" might explain the undoubted improvement in the trueness of the seed from a tree grown in proximity to other species, after isolation. This has been conspicuously shown in the case of *C. Ledgeriana* in Sikkim, the seedlings from which, since Mr. GAMMIE uprooted nearly all the neighbouring trees, now come remarkably true, whereas before that was done the sporting was so great that Dr. KING would not propagate by seed at all. The results have been even more marked in Java.

According to statements now forwarded to us by Mr. T. N. CHRISTIE, there can be little doubt that the plant figured by Dr. TRIMEN is recognized in Ceylon by the planters, as well as by Mr. MOENS, as the "true *Ledgeriana*." Some flowers and leaves marked A and B received from Mr. T. N. CHRISTIE correspond closely with Dr. TRIMEN'S figures in the *Journal of Botany*. The flowers are small and drooping and the buds not swollen abruptly below the apices, these being the features pointed out by Dr. TRIMEN as most characteristic of his plant.

The samples of bark corresponding to these specimens give the following results on analysis:—

Quinine	7·50	8·32
Quinidine	—	—
Cinchonidine	·19	1·12
Cinchonine	·18	·20
Amorphous	·60	·60
	8·47	10·24

The amount of cinchonidine in one of these samples is certainly not in favour of its being the produce of a true *Ledgeriana* plant. Mr. CHRISTIE says, "The plant which Dr. TRIMEN figured was one "of those raised from McIVOR's seed by me, and "planted on Mahanilu by Mr. AGAR, and its descent "from LEDGER's original seed is undoubted. Other "plants exactly similar in blossom, raised from the "same pinch of seed, have given over 12, 13, and 14 "per cent. sulphate of quinine, and the very trees "which Mr. HOWARD called in to help him, the "Yarrow Ledgers, have the same blossom and came "out of the same nursery bed as the Ledger figured "by Dr. TRIMEN. Before the least doubt had been "thrown upon his figured type, Dr. TRIMEN selected "a tree here for specimens, as being botanically a "typical Ledger, and his selection was well borne "out when on the following day the analysis of that "very tree arrived from England, and showed 11·29 "per cent. quinine sulphate." The specimens sent by Dr. TRIMEN to the Museum of the Pharmaceutical Society are considered by some not to be typical *Ledgeraina*, but more probably hybrids of *officinalis* and *Calisaya*. Concerning the satiny gloss and hairy margin of the leaves, which Mr. HOWARD appears to have put forward as characteristic of the true *Ledgeriana*, Mr. T. N. CHRISTIE remarks, "The "veriest tyro in cinchona cultivation could have "told Mr. HOWARD that these characteristics are "common to all *Ledgerianas* and all the *Cali*-"*sayas* when young and that there is not a sign of either in the mature foliage." It is difficult to understand this remark, for Mr. HOWARD must certainly have cultivated seed of Calisaya and would scarcely have pointed out the satiny gloss and hairy margin of the leaves as characteristic of the *Ledgeriana* if it occurred in other Calisayas, and it certainly was not present in all the Bolivian Calisayas exhibited by Mr. HOWARD and Mr. T. CHRISTY at the meeting of the Linnean Society. Mr. CHRISTIE also points out that while Mr. HOWARD is said to claim "on Mr. MOENS' own authority" that his plants alone are authentic, he repudiates Mr. MOENS' identification of Dr. TRIMEN's plant.

Mr. T. N. CHRISTIE claims that he, "having lived "for years beside mature *Ledgerianas* which have "given the highest analyses we have yet heard of, may "presume to think that he knows a *Ledgeriana* when "he sees it, and that Dr. TRIMEN, who has seen the "Ceylon and Indian plantations and many mature "analysed *Ledgerianas*, knows *C. Ledgeriana*, and that "the latter has figured it; and that Mr. HOWARD, "with the knowledge of hot-house plants and dried "specimens, does not know and has not figured *C.* "*Ledgeriana*." In support of this claim he refers to Kew Gardens 'Report,' 1880, p. 12, where it is stated that some plants grown from seed were forwarded by Mr. HOWARD to Kew, and through Kew to Mr. J. A. CAMPBELL, of Lindula, Ceylon; and three others from the same authentic strain, to Jamaica. Concerning those received by Mr. CAMPBELL, that gentleman writes to Mr. CHRISTIE, "No one who "knows a *Ledgeriana* tree of pure type would think "of calling the trees I have (raised from cuttings "received from Mr. HOWARD) *Ledgerianas*. Two "of them are very shrubby in their growth and with "hard shiny leaves. The other is a Calisaya of the "broad-leaved variety very much like what I believe "is called in Java, *Calisaya Anglica*. I have also "another plant that Mr. HOWARD gave me, which "I understood him to say had been raised from "*Ledgeriana* seed, received from Java. This is the "best, so far as appearance goes, but I should not "call it a *Ledgeriana*."

It is not surprising that Mr. HOWARD should refer Dr. TRIMEN's *C. Ledgeriana* to *C. micrantha*, since in the 'Quinology of the East Indian Plantations,' p. 84, Mr. HOWARD remarks:—"By placing "my plate of the B-form of *Ledgeriana* beside that "of *C. micrantha* in 'Nueva Quinologia,' the reader "will be struck with a certain kind of analogy and "general resemblance." In a previous note on p. 5, he says:—"It is specially remarked by G. M. VAN "GORKOM that about three thousand plants raised "from seed from British India present quite a "peculiar character, which partly belongs to the "*Calisaya micrantha*," and adds, "I assisted at "the purchase of the bag of seeds (collected by "LECHLER*) for British India, to which no doubt "this refers, and having some growing freely side by "side with the *C. micrantha*, brought by PRITCHETT "from Huanuco, can quite confirm their resemblance. "The plants are, I think, those of the *C. micrantha* "(Bolivian variety) of WEDDELL." According to these remarks it would appear that Mr. HOWARD considered the plants raised from LEDGER's seed to strongly resemble *C. micrantha*, and his reference of Dr. TRIMEN's *Ledgeriana* to *C. micrantha* is therefore easily understood.

Mr. HOWARD's plates of *C. Ledgeriana* do not seem to belong to one distinct form, such as is recognized by Dr. TRIMEN and the Ceylon planters, since one variety has the flowers light-red, and another has scrobicules much more numerous than in the two others, and Dr. WEDDELL himself seems to have thought this, as indicated by his remarks ('East Indian Quinology,' p. 85):—"I think you

* Corrected to "LEDGER" on p. 84.

"are quite right in considering your two Java "plants as constituting a distinct variety of *C. Cali-* "*saya*, but whether one of the two forms you have "had pictured is worthy or not of being ranked as a "sub-variety of the other could hardly be affirmed "without comparing a considerable number of spe- "cimens."

Mr. HOWARD doubtless has a right to claim, not only on account of his special acquaintance with the subject, but also as a botanist, that a cinchona, not corresponding with his published description and plates, should not be called by the name he has adopted. In this case, if Dr. TRIMEN'S plant be distinct from what Mr. HOWARD has described, then the name of *C. Ledgeriana*, Moens, for the tree distinguished by the Ceylon planters as Ledger Cinchona is, to say the least, confusing, and the awkwardness would be best avoided by the adoption of a different name for Dr. TRIMEN'S plant. Mr. HOWARD seems to have recognized the likeness of his own *Ledgerianas* to *C. micrantha* when they first came into his hands, and now attributes the same likeness to Dr. TRIMEN'S plant. Moreover, it is understood that Mr. HOWARD, in selecting his types from a number of specimens, was partly guided by their large yield of quinine. The analysis of Dr. TRIMEN'S plant showed it to be equally rich in quinine, and the specimens now sent by Dr. TRIMEN show the same result. In any case, the question whether Dr. TRIMEN'S *Ledgeriana* and Mr. HOWARD'S *C. Calisaya*, var. *Ledgeriana*, are identical or not obviously requires further elucidation.

We must, however, admit that we do not understand the botanical part of the subject sufficiently to offer any opinion upon the point at issue or even to say with certainty what that point is. But at the same time the subject is of such importance, and has gained such an amount of public notice, that we think it desirable to place before our readers, so far as we can, a statement of what has been said upon it, without, however, accepting any responsibility for supporting either view.

In reply to a question by Sir Trevor Lawrence, the Prime Minister stated in the House of Commons on Monday night that it was undoubtedly the intention of the Government to proceed with the Medical Acts Amendment Bill, but as it was a measure that had come down from the House of Lords, precedence had been given to other Bills, hence the delay. The Second reading of the Bill was on the paper for Thursday, but at the time of going to press it had not been reached.

* * *

The Petroleum Bill was on the 3rd instant read a second time in the House of Lords and referred to a Select Committee, which met on Monday and again on Thursday. At a meeting of members of the Petroleum Association and others engaged in the petroleum trade, held on Wednesday, strong opposition to the provisions of the Bill was expressed.

SOCIETY OF ARTS.

SOLID AND LIQUID ILLUMINATING AGENTS.*

BY LEOPOLD FIELD, F.C.S.

Lecture I.

You, who come from stations lighted by electricity, and through streets brilliant in gas light, may find good cause for wonder that so much can be found to be said upon out-of-date subjects like the lamp and the candle, which are the simple equivalents of the title of these lectures.

The system according to which I have concatenated the various bodies, used for lamps and candles, is based upon the theories held by the generality of modern chemists. Every member almost of these myriad—these Mormon—families, can be assigned to one or the other of the four groups—hydrocarbons, alcohols, ethers, and acids. Hydro carbons may be regarded as parents of the others, which in theory, borne out to a certain extent by experiment, are derived from them by more or less complicated processes. As their name implies, the hydrocarbons consist entirely of hydrogen and carbon. The relative proportions of these elements in the different series vary by equal increments. First on the list, as to us they are most important, come the paraffins. The white solid familiar to us under that denomination consists of a number of the higher homologues of this series, the composition of which is so nearly identical as to defy the most cunning attempts at isolation. At the present time twenty well defined paraffins have been individualized. They all conform to one typical formula C_nH_{2n+2}, and are all very inert, characterless compounds, to which qualities they owe their name (*parum*, little, *affinis*, akin). The first of the twenty has long been known—it is the joy of the lecturer, as methane; the wonder of the bucolic, as marsh gas; and terror of the miner, as fire damp. The formula of methane is CH_4. It is a colourless gas, becoming liquid only under extreme cold and pressure. Its sp. gr. is ·55. Here is a cylinder of it: observe the bright, smokeless flame, characteristic of the paraffins generally. In this short, stout tube, there are confined four volumes of oxygen with two of methane: applying a light, the brisk detonation suggests that methane, at least, has kindred feelings to oxygen. But the methane exists no longer; at the moment of union, water and carbon dioxide—the dreaded chokedamp—were formed—

$$CH_4 + O_4 = CO_2 + 2H_2O.$$

Marsh gas is the invariable concomitant of slow organic decomposition. The formation of coal was attended with evolution of this gas, large volumes of which are often stored in coal mines. The mud-volcano of Bulganak, in the Crimea, belches forth pure CH_4. The fire-worshippers of Baku, according to O'Donovan,† prostrate themselves before a stream of this gas. It is also seen dancing over marshes, ablaze, as Will-o'-the-Wisp. Methane and the three following members, ethane, C_2H_6, propane, C_3H_8, and butane, C_4H_6, are gases of density, increasing with their molecular weights. The fifth, pentane, C_5H_{12}, is a liquid at 38° C., and so till the sixteenth, hexdecane, $C_{16}H_{34}$, solid at 21° C. Ethane, C_2H_6, is noteworthy as the parent of alcohol, ether, and acetic acid.

The paraffins allow of substitution products with the haloids, that is, they give up two atoms of hydrogen in exchange for an equal number of atoms of chlorine, bromine, or iodine. This is important, as the *substitution* compounds thus formed are identical with the *additive*

* Cantor Lectures. Reprinted from the *Journal of the Society of Arts.*

† O'Donovan, 'Merv Oasis.'

compounds of the haloids with the olefins; which are the next series. These bodies have C_nH_{2n} for their typical formula. Like the paraffins, they are colourless, readily inflammable, forming carbon dioxide and water. They are, however, much more easily acted upon by acids, and combine directly with the haloids. Here we have olefiant gas or ethylene, the first of the class, burning with a flame much resembling that of methane. In this jar, inverted over water, I have two volumes of ethylene. Passing up from this bottle an equal proportion of chlorine, you will see the water, at first displaced, soon rise rapidly, while drops of an oily liquid collect in the apex of the funnel, whence they can be drawn off afterwards. This oily pungent liquid is ethylene dichloride, called of old, Dutch liquid. The name olefiant—oil making—is attributable to this property.

The reaction, as before mentioned, is additive, and symbolized thus:—

$$\underset{\text{ethylene}}{C_2H_4} + \underset{\text{chlorine}}{Cl_2} = \underset{\text{ethylene dichloride}}{C_2H_4Cl_2}$$

which is identical with the substitution product formed by the action of chlorine upon methane.

With the exception of cetene and cerotine, constituents of wax and spermaceti, the other olefines are of no interest to us. What renders ethylene of moment is the method of its formation from acetylene, the head of the third series of hydrocarbons, called acetylenes.

The typical formula of these is C_nH_{2n-2}. We will only take acetylene itself, C_2H_2. Owing to the preponderance of carbon, it burns with a smoky reddish flame. Though colourless, acetylene possesses a strong unpleasant smell, familiar to all who have allowed Bunsen burners to ignite below. In fact, as methane is always attendant upon slow decomposition of organic bodies, so acetylene is formed in every imperfect organic combustion. The feature of salient interest in its character is its production from the direct union of carbon and hydrogen. When a stream of the latter is passed over the carbon electrodes of a powerful battery, combination takes place, thus:—

$$C_2 + H_2 = \underset{\text{acetylene.}}{C_2H_2}$$

Now, if nascent hydrogen act upon cuprous acetylide, we obtain ethylene, which combination we may depict simply as:—

$$\underset{\text{acetylene}}{C_2H_2} + H_2 = \underset{\text{ethylene}}{C_2H_4}$$

Again, by the action of sulphuric acid upon ethylene, ethylic alcohol, or spirits of wine, is formed:—

$$1.\ \underset{\text{ethylene.}}{C_2H_4} + H_2SO_4 = SO_4HC_2H_5$$

$$2.\ SO_4HC_2H_5 + OH_2 = \underset{\text{sulphuric acid}}{H_2SO_4} + \underset{\text{ethylic alcohol}}{C_2H_5OH}$$

And as from ethylic alcohol most other organic compounds may be built up, we may be fairly said to have started *ab ovo*, and call acetylene the tap-root of organic compounds. I must not detain you now with the remaining hydrocarbons, the benzines, terpenes, etc., which are adduced as playing, or having played, some part in the drama of lighting. Nor will we linger long over the alcohols, ethers, and acids, except for just such space as will give us an insight into the meanings and propriety of application of the terms. The alcohols owe their name to ethylic alcohol, the alcohol *par excellence*, our national beverage, commonly called spirits of wine. The word alcohol itself comes from the Arabic, *al kohol*, antimony. This metal, very subtlely powdered, was applied as a pigment to the brows of oriental beauties. Soon any very fine powder was called alcohol. We find Boyle talking of reducing a body to a very "subtile powder or *alcohol*, as the chemists speak." Ultimately, the epithet passed to all "subtile" bodies, and so to spirit of wine. The modern chemist then gave the name to a great order of compounds, which stood respectively in the same relation to hydrocarbons as ethylic alcohol does to its parent ethane; from which it is formed by the substitution of OH, hydroxyl, for H.

$$\left.\begin{matrix} C_2H_5 \\ H \end{matrix}\right\} + O = \left.\begin{matrix} C_2H_5 \\ H \end{matrix}\right\} O$$

ethane, or ethylhydride=ethylic alcohol.

Ethylic and methylic (μέθυ, wine) alcohols have been used for illuminating ends, when tempered with some carbonaceous substance. Here is pure spirit, burning, as you see, non-luminous; and here some spirit in which camphor has been dissolved. This, you perceive has a bright flame. But the sole use of methylated spirit to the chemist now is for heating; the flame gives very great heat; as Boyle remarks—"In lamp furnaces wherein I have used spirits of wine for oil, the same flame has melted foliated gold." The alcohol of chief interest to us, though not itself a luminant, is glycerine, of which later on.

The ethers (αἴθω, I burn) may be regarded as formed from the alcohols, by the substitution of another radicle for H. In fact, the alcohols may be called the hydrates of the anhydride ethers, as in metallic compounds of the same nature. So we have ethylic ether, and ethylic alcohol, formed from ethane, which may, in its turn, be regarded as a hydride of the radical ethyl. The following arrangement gives a brief idea of the view which is taken of the formation of the whole chain, from the melecule of hydrogen to that of acetic acid:—

$$\underset{\text{hydrogen}}{\left.\begin{matrix} H \\ H \end{matrix}\right\}} \ : \ \underset{\substack{\text{ethylhydride} \\ \text{(ethane)}}}{\left.\begin{matrix} C_2H_5 \\ H \end{matrix}\right\}} \ : \ \underset{\substack{\text{ethylhydrate} \\ \text{(alcohol)}}}{\left.\begin{matrix} C_2H_5 \\ H \end{matrix}\right\} O} \ :$$

$$\underset{\substack{\text{ethyloxide} \\ \text{(ether)}}}{\left.\begin{matrix} C_2H_5 \\ C_2H_5 \end{matrix}\right\} O} \ : \ \underset{\substack{\text{aldehyde} \\ \text{(alcohol dehydrated)}}}{\left.\begin{matrix} C_2H_3 \\ H \end{matrix}\right\} O} \ : \ \underset{\text{acetic acid}}{\left.\begin{matrix} C_2H_3 \\ OH \end{matrix}\right\} O} \ :$$

Acetic acid is more properly regarded as being formed from methane, by substitution of—

CO.OH (carbhydroxyl) for H:

$$\underset{\substack{\text{methane} \\ \text{(methyl hydride)}}}{\left.\begin{matrix} CH_3 \\ H \end{matrix}\right\}} + CO.OH. = \underset{\text{acetic acid.}}{\left.\begin{matrix} CH_3 \\ CO.OH \end{matrix}\right\}}$$

Ether also is itself of no consequence here, but the compound ethers, as tallow and palm oil, will fully vindicate the brief attention we have paid the chief of their clan. The word acid originally meant a substance of a sour taste, which acted upon metals. Working upon the typical properties of the first definite acids, as sulphuric and hydrochloric, the name is now bestowed upon an indefinite number of bodies; their qualification being the possession of hydrogen atoms, which they can exchange for metals or radicles. Considering that every flower, berry, insect, animal, metal; in short every body, animate or dead, furnishes a peculiar and distinct acid, it is not surprising that the number is large. Of the substances with which we have to deal, cocoanut oil alone furnishes ten different acids, and beeswax three.

There is an immense deal more to be said about the permutations and combinations possible between organic compounds. Time, and the fear of wearying you, forbid my pursuing the subject further.

Probably the earliest known means of lighting was the *torch*, used largely of old in north countries, and still, no doubt, lighting the Lapp and the Finn. This torch has been sent me from North Germany. It is cut from the pitch pine, and sticky with exuded resin. I will light it; you see the red large flame, and the volumes of smoke. This will presently condense into small particles of soot, colloquially termed "blacks," which adhere to faces and clothes with surprising determination, and may give some idea of the eminent comfort experienced in a hall lighted, like the Walhalla, with pine-splinters—*kien-spähne*. We may presume that, in cooking, some of the fat might saturate a brand, which would burn long without consuming its fibre. Or, perhaps, that the readier and brighter combustion of certain woods was attributed correctly to the resin they contained. This is the crude idea of a link—even of a candle. Substituting a rope for a splinter, and saturating this with pitch or resin, we have the *link* that still, on foggy days, connects us with the past. For the word, and, most probably, the idea, comes from the Greek, λύχνος, or perhaps the Latin *luchnus* (Cic.), as the German "fackel," from the Greek φάκελος (*faggot*), a bundle of sticks—after, a torch. Our word torch, though, is evidently the Latin "*tortitium*"—a twisted thing, which would now be applied more properly to the link; while our pine torch finds its Roman equivalent in *tædæ*—slips of the *tæda*, or Italian pitch pine—the usual outdoor light of Rome. Funalia, with which Virgil tells us Dido's palace was lighted (evidently from "funis," a rope)—

> "—dependent lychni laquearibus aureis
> Incensi, et noctem flammis funalia vincunt,"*

were probably *flambeaux,* a finer kind of link. Here we have specimens both of link and flambeau, disinterred from Lambeth cellars, where they have lain, perhaps, half a century.

The link, giving an eager, smoky flame, was held by the running footmen or linkboys, who quenched their light in the large extinguishers still to be found on houses of aristocratic antiquity. The flambeau has a centre of oakum, surrounded with alternate layers of rosin and crude beeswax, finished off with a coating of the latter, bleached, which gives it a very expensive appearance. This description of torch was more costly, and gave a cleaner flame than its brothers; and so was principally employed in lighting halls, staircases, etc. At what period the torch was superseded, and whether by lamps or candles, is, and will remain, a moot point. The fact is, the Greeks and Romans, regarding lighting as of very minor importance, were shockingly loose in their nomenclature. Nor are we much better in English. In our translation of the Scriptures the words "candle" and "candlestick" are used indiscriminately with "lamp;" though it is quite certain that a *bonâ fide* candle was not known. For example, in Exodus xxv., 31, we have "a candlestick of pure gold," but, from the after text, we may be certain that the right word should be "lampstand." Again, in Matt. v., 15, the words "men do not light a candle and put it under a bushel, but on a candlestick," would seem to positively attest the use of both candle and stick at that period, did we not know that the Latin *candelabrum*, and Greek λυχνία, Latin, *luchnuchus* (Cic.), meant "lampstand." Furthermore, as in the parable of the virgins, where oil is a specified condition, the word λύχνος is rendered lamp (Matt. xxv., 1–5). The confusion of names seems strange to us now, with whom lamp and candle enjoy such distinct individuality; but in old times, no doubt, the terms were interchangeable. Etymology shows the words to be derived from roots signifying to shine or burn—as, candela, κανδήλα, akin to *candeo*, to shine (Persian *kandeel*), (Sans. *kan*)—λύχνος, lucerna, from *lux*, light, (Sans. *lôk*), λάμπας, *lampas*, probably connected with *lame*, and the Hebrew *lapad*, to shine.

We are, I think, safe in concluding the torch to have been superseded by the lamp, and it is interesting to perceive how this is evidenced in mythology. Ceres, in the old legend, sought her daughter in Hell with a torch; Apuleius makes Psyche drop hot oil on Cupid from a lamp. Whether candles, properly so-called, *i.e.*, wicks surrounded with coatings of wax or tallow, were known before or after the use of lamps had become general, I cannot say. We have a passage from Martial (first century, A.D.), in which the candle is mentioned as an old affair. Says he:—

> "Nomina *candelæ* nobis antiqua dederunt,
> Non nôrat parcos uncta lucerna patres."
> (Ep. xiv., 43.)

But here he may mean torch—*funalia*—which the old Romans would more probably call *candela*, from its shining qualities, than *funalia*, in allusion to its manufacture. In the Greek, the word κανδήλα is derived from the Latin, and is not met with till the time of Athenæus, who lived in the reigns of Aurelius and Commodus (about 150-220 A.C.) In his 'Deipnosophistæ' we find one telling a waiter to bring farthing dips:—

> ἐμοι δέ παῖ δωρόιδειπνε ἀσσαρίου κανδήλας πρίω.

By this, no doubt, a rushlight is intended to be understood, which article had at that time come pretty generally into use.

But the most valuable information on this point is obtained from a passage in Apuleius' Metam. iv., where, at a noise in the dead of night, the household runs in with "*tædis, lucerna, sebaceis, cereis, et ceteris,*" that is, with torches of pine, lamps, tallow candles, and wax tapers. This is a decisive proof that candles both of wax and tallow were used. They were, however, at no time considered as respectable as the lamp, for we find in another verse of Martial (Apoph. 42.)

> "Hic tibi nocturnos præstabit cereus ignes
> Subducta est puero namque lucerna tuo."*

An apology for giving his friend a wax light, as his footman has walked off with the lamp. At Herculaneum, a chandler's apparatus was found, and in the British Museum there is a fragment of a huge candle found in Vaison, near Orange, and supposed to have been made about the first century, A.C. (Juvenal, iii., 287, also talks of the "breve lumen candelæ.") The wick of such candles would probably be the pith of rushes—*scirpus*—rudely covered with crude wax or tallow, and rolled into shape. Candlesticks to hold these existed, but later on with a spike to penetrate the butt of the candle. The name *candelabrum,* however, was applied generally to the pillar on which the oil lamp was placed, or from which it was suspended. I have here both diagrams and specimens of lucernæ and candelabra. This one especially deserves notice, as being a genuine bronze candelabrum, said to have been found in Herculaneum. The lamp upon it is a fair representative of its class, scarcely ornamental enough, perhaps, to be worthy of such a support, but the combination of the two will give you an accurate idea of a Roman house-lamp. I have given it a wick of oakum (*stuppa*), and filled the body with crude Italian olive oil, thus imitating, as exactly as may be, the actual light. Not a very brilliant one you will say, and smoking exceedingly. So did all old lamps of necessity, no attempt being made at creating the current of air requisite for proper combustion. You may imagine the state of a room the morning after a symposium, when, perhaps, a dozen lamps had been burning for six hours, smoking fearfully, without the least appliance for the escape of the heavy carbonaceous fumes. Indeed, it was one slave's recognized duty to go round in the morning wiping the sooty pictures and statues. The only instance, to my recollection, of a flue existing, was at the Erectheum of the Athens Acropolis. The lamp was of pure gold, and so large as to require replenishing only once a year. Callimachus designed it for the new temple, about 400 B.C., and provided it with a chimney, in the guise of a bronze palm tree inverted. Otherwise, the smoke appears to have been regarded as an unavoidable evil. Certain it is that, however magnificent and elaborate the design,

---

* This reminds us forcibly of Milton's description of Pandemonium—

> "From the arched roof,
> Pendent by subtle magic, many a row
> Of starry lamps and blazing cressets, fed
> With naphtha and asphaltum, yielded light
> As from a sky.

* Pliny, xxxiv., 3–6, speaks of "the extravagant prices of candelabra, which take their name from *so poor a thing*."

the economy of the light remained stationary. A wick, sometimes of oakum, sometimes of the dearer Carpasian flax (cotton?) passed through the nozzle into the body, filled generally with olive oil; though according to Pliny, bitumen was occasionally used. This is the less surprising, as Italy, in parts, is rich in springs of that mineral and petroleum. In the East, especially among the tribes dwelling in the vicinity of the Lacus Asphaltites, or Dead Sea, bitumen and naphtha were extensively consumed for lighting and other purposes. Perhaps *Nephi*, the sacred pit-fire, was of this nature; and, to speculate further, the emphasis laid upon the use of olive oil in the tabernacles of Israel may have been an implied condemnation of the mineral combustible, as peculiar to heathen ritual. Mr. Basil Cooper, the well-known Egyptologist, has kindly suggested to me a very fascinating etymology of the word *naphtha*—viz., NA, water; of PHTHA, the Hephæstos, or Vulcan of Egypt's deities, the god of fire. This is endorsed by the fact that the Indians, who sold the first petroleum as *Seneca oil*, and used it largely in their rites of worship, termed it *fire-water*, which name has descended to alcohol. About bitumen and its kindred we shall speak under the heading petroleum.

The introduction of lamps into Greece was gradual and slow. Probably by the end of the fifth century, B.C., they were in general use in the upper ranks of society. Herodotus, (ii., 62), writing of the *Lychnokaie* (feast of lamps) at Sais, in Egypt (450 B.C.), does not express surprise at the lamps themselves, but only at the great number thereof. Their lamp differed in no way from that of Rome; the wick (θρυαλλίς) made from the woolly leaves of an indigenous plant, passed through the nose (μυκτήρ) into the crude olive oil. Those who wish to become more intimately acquainted with the various styles of ornament in vogue among old nations, will find every conceivable shape and size in the Etruscan Vase gallery at the British Museum, to which I must beg to refer them for further illustration. Becker's 'Gallus' and 'Charicles' also are replete with information on this point. I could not pursue the subject further, without trenching on the ground of my future lectures, in which the main subject will always be prefaced by an outline history of that branch. You will be surprised to find both our latter day inventions foreshadowed in extreme antiquity, and the imperfections of the dark ages maintained to a recent date.

It is worthy of comment, in conclusion, how fire and light have ever been invested with celestial attributes, and reserved for divine worship. I need only instance the Caspian fire-worshippers, and the Persian monarchs, with their silver fire trays borne before them into battle. Great festivals of lamps have been common to all nations. The *Lychnokaie*, above mentioned as an Egyptian lamp-feast, has its parallel in the Chinese feast of lanterns. We send out annually many thousand scarlet candles, —*lobchocks*—for this festival, which happens on the fifteenth day of the first month. Then the Greeks had their λαμπαδη-δρομία, and the Romans their *Lupercalia*. In lieu of this feast, remarkable for its licentiousness, Pope Gelasius instituted Candlemas, falling on the 2nd February. Some have it, that Vigilius supplanted the *Proserpina* by this festival. Anyhow, though the significance be changed, candles play the chief *rôle* in both. According to Pliny ('Nat. Hist.'), the Romans themselves used wax candles in certain rites. I need scarcely hint at the eternal lamp of Vesta, tended by damsels of established reputation; the never-dying lights of Mahomet's tomb, Aaron's tabernacle, and Roman Catholic churches. The Romans lighted lamps in honour of Prometheus, who caught fire from heaven, of Minerva, who gave them oil, of Vulcan, who invented lamps; birthdays were sometimes called days of lamps, as the bulk of their gifts took that form, in cheap terra-cotta or costly metal; there was the *fax belli* or war torch, and *fax nuptialis*, the emblem of marriage.

"There let Hymen oft appear,
In saffron robe, with taper clear."
Milton ('Allegro').

On the tombs of the dead, lamps were placed by the sorrowing hands of their legatees, filled with scented oil. An oracular statue of Hermes, in Achaia, was "worked" by lighting a lamp before him, and placing a small coin at his feet.

Ingenious suggestions have been made about eternal lamps in tombs, which are positively averred to have been found burning after the lapse of centuries.

"Our wasted oil unprofitably burns,
Like hidden lamps in old sepulchral urns."
Cowper ('Conversation').

Indeed, Rosicrucius gives a description of his eternal lamp, with all the circumstance of discovery. "But this," says Disraeli, "is only dwelt on to make it appear that he did discover something." Boyle undertook a series of experiments with the air-pump, which demonstrated the absurdity of such statements. Reserving my private opinion as somewhat iconoclastic, I might suggest the possibility of an asbestos wick, communicating with a supply of light naphtha, burning indefinitely in a tomb not absolutely air-tight. Possibly, also, highly carbonaceous vapours in the sepulchre might have been kindled by the intruded torch.

After this hasty glimpse at our wretchedly illumined forefathers, you will be more than ever inclined to endorse Lamb's opinion, that "one can never hear mention of them without an accompanying feeling, as though a palpable obscure had dimmed the face of things, and that our ancestors wandered to and fro—groping."

SOCIETY OF CHEMICAL INDUSTRY.

Stassfurt Salts and their Mode of Treatment.

BY C. NAPIER HAKE.

(*Concluded from page 57.*)

The raw potash or carnallite salt has the following composition in 100 parts:—

		Per cent.
Chloride of potassium	carnallite	16·2
Chloride of magnesium	carnallite	24·3
Sulphate of magnesium—kieserite		9·7
Common salt		18·7
Chloride of calcium		0·2
Clay and anhydrite		2·1
Water		28·8

I propose first to describe the process by which the chloride of potassium is separated from this raw material, and shall then speak of the bye-products and waste products and their treatment. The manufacture of chloride of potassium is based on the decomposition of the carnallite, contained in the raw material, in a hot saturated solution, potassium chloride separating out on cooling and chloride of magnesium remaining in solution. The process, though simple in theory, is complicated in practice, owing to many difficulties, some of which I shall presently mention. The process of manufacture may be divided into four operations:—

1. Dissolving the raw salt.
2. Evaporating its cold mother liquor.
3. Dissolving the artificial carnallite resulting from the evaporation.
4. Refining the crystallized chloride of potassium.

The raw salt is delivered by the mines to the various factories in an unground state. The large blocks are broken up by a stone breaker, or by a mill of similar construction to a coffee mill, and the material is then lifted, by means of an elevator, into the dissolving pan, a cylindrical wrought-iron vessel, in which is contained a boiling saline solution, preferably of chloride of magnesium. The solution is kept boiling by high-pressure open steam, as the salt is delivered into it. The carnallite dissolves entirely, but the kieserite and common salt to a small extent only. The resulting hot solution which has a specific gravity of 1·32, is then run into deep pans, the sides of which are surrounded by some non-conducting substance. Milk of lime is sprinkled over the surface of the turbid liquor, which decomposes a small portion of the soluble magnesium salts, magnesia being formed, which, on subsiding, carries down with it the fine precipitate of sulphate of calcium. This fine precipitate is formed during the boiling of the solution from the double decomposition of the chloride of calcium contained in the tachydrite with sulphate of magnesium. This method of clarifying the liquor has, after many experiments, been found to be the best and also the cheapest.

The hot solution, thus clarified, is then run into shallow pans and allowed to cool for two or three days. Two-thirds of the potassium chloride contained in the solution crystallizes out and a part of the common salt with it. By this method the first product of crystallization, when refined, contains from 80 to 85 per cent. KCl.

By another method the solution is boiled to specific gravity of 1·34 instead of 1·32, chloride of magnesium liquor being used as a solvent. The solution is then run into the settling pan, and diluted down to a specific gravity of 1·32, in order to prevent the separation of chloride of potassium as carnallite, which would otherwise take place at the higher grade. Less common salt is dissolved in the first place, consequently the solution is much richer in potassium chloride. The first product of crystallization, after being refined, is an almost pure potassium chloride, and is not less in quantity than by the first method. This simple process was introduced by Dr. Dupré into the works of Messrs. Leisler and Townsend in the year 1862, and was successfully kept a secret for fifteen years. It is now universally in operation.

As regards the cold mother liquor, the composition of this in 100 parts is as follows:—

	Per cent.
Chloride of potassium	4·09
Chloride of sodium	1·74
Chloride of magnesium	20·49
Sulphate of magnesia	2·98
Water	70·70

In order to obtain the 4 per cent. of chloride of potassium still remaining in this mother liquor, the solution is concentrated by evaporation to a specific gravity of 1·34, when the chloride of potassium almost completely separates out, on cooling, in the form of double chloride of potassium and magnesium, or artificial carnallite, this double salt being insoluble in a concentrated solution of chloride of magnesium. The double salt is allowed to drain, and is then dissolved in boiling water to saturation, and on cooling, deposits a very pure chloride of potassium. The chloride of potassium resulting from the various operations described is further purified by steeping in cold water, and is then allowed to drain, when it is afterwards either calcined at a gentle heat in reverberatory furnaces or dried by steam in specially constructed pans. It is generally exported packed in jute bags containing 2 cwt. each.

The bye-products resulting from the process just described are kieserite and Epsom salts, crystallized and anhydrous sulphate of soda, a mixed salt which is sold as potash manure, chloride of magnesium, magnesia hydrate and bromine. The first four, viz., kieserite, Epsom salts, crystallized and anhydrous sulphate of soda, are obtained from the residue remaining in the pan after the potash salt has been dissolved out of the raw material. The product sold as potash manure is obtained from the sludge remaining in the settling pan. The last three, viz., chloride of magnesium, magnesia hydrate, and bromine, are obtained from the last mother liquor. With regard to the first four, the deposit, which represents 30 to 40 per cent. of the raw material used, has the following composition:—

	Per cent.
Sulphate of magnesia	26·8
Common salt	34·2
Chloride of magnesium	9·9
Chloride of potassium	2·1
Sulphate of calcium	8·5
Anhydrite	10·3
Water	8·2

The deposit, while still hot, is thrown out of the dissolving pan into a funnel-shaped iron box, at the bottom of which is a grating with bars about ¼ inch apart. A shower of cold water is allowed to play on the surface, by which the common salt is dissolved. The kieserite breaks up into very fine particles, and passes through the grating as a sludge in suspension, accompanied by small quantities of undissolved common salt and crystals of anhydrite. It next passes into a drum sieve, which revolves by the action of the flowing liquor. The finely-divided kieserite falls through the meshes into a pan below, the impurities passing over and along, and falling out at the other end. The kieserite is then allowed to subside, and is rapidly formed into blocks weighing from 50 lbs. to 70 lbs. each. Within a few hours these become very hard from the absorption of 1 molecule of water, in which condition it is exported, without the necessity of further packing. It contains—

	Per cent.
Sulphate of magnesium	60
Sulphate of calcium	5
Common salt	3
Anhydrite	10
Water	22

The kieserite serves as a raw material, in Stassfurt and elsewhere, for the manufacture of Epsom salts. The process consists simply in dissolving it and allowing the hot solution to crystallize.

This same deposit also serves as a raw material for the manufacture of sulphate of soda, which can, however, only be carried on during the winter months, when the thermometer is at 0°. The residue is thrown from the dissolving pan and collected outside the works in large heaps, where it remains exposed to the action of the air until the kieserite, from the absorption of water, is converted into a more soluble form. When the heap accumulated is in a sufficiently soluble condition, a shallow trench is dug round it and puddled out with clay, with an outlet leading to a large tank. A steam and water pipe is laid side by side from the works on to the heap, and hot water injected over the surface continuously. A concentrated warm solution of common salt and sulphate of magnesia runs out at the bottom of the heap, and collecting in the trench flows into the tank, where it is allowed to clarify. The clear liquor is pumped into shallow wood reservoirs standing in the open air. One cold night affords sufficient time for the complete separation of sulphate of soda from this solution.

As much as 10,000 tons of sulphate of soda have been produced in Stassfurt during one winter. The crystallized salt is either recrystallized or is converted into anhydrous sulphate, either by calcination or by Pechiney's process, which consists in adding to a concentrated hot solution 17 to 20 per cent. of common salt. About 85 per cent. of the sulphate of soda present in the solution separates out as the anhydrous salt. Pechiney's process is used by the Stassfurt Chemical Company only, other manufacturers preferring to dehydrate the crystals by calcination. The residue remaining in the settling pans yields a not unimportant bye-product. This residue, which is in a more or less fluid state, is run into large reservoirs, in which the solid matter is allowed to subside, and the supernatant liquor is siphoned off. The still thin sludgy mass is thrown on to a sloping platform of brickwork, where is it left until it is sufficiently drained to bear transport, when it is calcined. The hard, partially-fused mass is then ground to a fine powder, and is packed in bags, each containing 2 cwt., and exported as a potash manure. The composition of this mixture will be seen from the analysis given below:—

	Per cent.
Chloride of potassium	15·0
Chloride of magnesium	19·8
Chloride of sodium	13·1
Sulphate of magnesium	16·8
Insoluble	35·3

It is a curious fact in connection with the calcining of this sludge that though the heat is sufficient to melt the mass only 5 per cent. of the chloride of magnesium present is decomposed. This is no doubt due to the presence of other salts, especially sulphates. In spite of the low percentage of potash in this so-called "potash manure," and of the high percentage of chloride of magnesium and other salts, which can scarcely be called fertilizers, it has an enormous sale, principally in Russia and the colder northern parts of Europe.

The last mother liquor supplies three bye-products, namely, crystallized magnesium chloride, magnesium hydrate, and bromine. This liquor has a specific gravity of 1·32, and consists of—

	Per cent.
Chloride of magnesium	35
Chloride of potassium	1
Chloride of sodium	1
Sulphate of magnesium	3
Bromide of magnesium	0·2
Water	59·8

The crystallized chloride of magnesium is produced by evaporating the mother liquor to a specific gravity of 1·34. The potassium and sodium chlorides and the magnesia sulphate separate out, and the hot concentrated liquor is run into casks, where it solidifies to a white translucent mass on cooling, containing about 50 per cent. of chloride of magnesium. It is largely exported to this country, being used by cotton spinners as a thread lubricator. The cost of production of one ton of crystallized chloride of magnesium in Stassfurt, including casking, is about 16*s.*

The Consolidated Alkali Company manufacture large quantities of magnesia hydrate by the following process: The 3 per cent. of sulphates contained in the last mother liquor are first removed by a solution of calcium chloride. A quantity of milk of lime is then added, rather less than sufficient to decompose the whole of the chloride of magnesium. The precipitated magnesia is allowed to settle as far as practicable, and is then passed through filter presses, in which it is thoroughly washed by water. The magnesia thus prepared contains only 0·1 per cent. sulphate of lime, and is used by Continental sugar refiners as a clarifier.

A certain quantity of this mother liquor is utilized for the distillation of the bromine contained in it. This is carried out in large sandstone vessels saturated with tar, binoxide of manganese and sulphuric acid being used to liberate the bromine.

Many proposals have been made and numerous patents have been taken out for the further utilization of this mother liquor, but it still figures largely as a waste product. Of the 6,000,000 cubic feet yearly produced, corresponding to 150,000 tons of dry $MgCl_2$, one-half only is recovered, the remainder being run into the river, carrying with it 300,000 lbs. of bromine.

The coal used in this industry is a lignite, the heating value of which is about one-third that of English coal. Large deposits exist in the immediate neighbourhood. The absence of good and cheap coal is a serious drawback to the development of a new industry, and this is one of the greatest difficulties manufacturers have to contend with. Another difficulty is that the water in Stassfurt is saturated with sulphate of lime, the river water in the immediate neighbourhood of the works not being available for manufacturing purposes, owing to excessive pollution by salt liquors. Thus manufacturers are compelled to study the economical use of fuel in the construction of their plant.

The dissolving pan, which is usually 7 feet in diameter and 8 feet deep, is entirely closed and steam tight, except where an iron tube passes into it. This tube is 1 foot in diameter, and projects about 2 feet above the cover of the pan. The coarsely-ground raw material falling from the elevator passes through the tube into the dissolving pan, in which there is a quantity of boiling mother liquor sufficient to close the lower end of the iron tube. Only just sufficient steam is allowed to enter so as to keep the solution gently boiling. If the steam valve is opened too much the contents of the pan are forced through the iron tube. With a little experience and care this result is easily avoided, and the arrangement works well, and the solution is completed with the use of a minimum amount of steam. The pans used in Stassfurt for evaporating the mother liquors are variously constructed. In the works built by Messrs. Leisler and Townsend, which have now passed into the hands of the Stassfurt Chemical Company Limited, the whole of the mother liquor is concentrated in iron pans by high pressure steam contained in copper coils, the condensed water being used for feeding the steam boilers. Messrs. Wüstenhagen and Company, in Heklingen, have constructed an evaporating pan which, I believe, gives good results as regards economizing fuel. In another method of dealing with the mother liquors, the pans, which are 15 feet to 20 feet long and 4 feet wide and about 3½ feet deep, are arranged in sets of three, and to each set a condenser is attached—that is to say, an iron reservoir, in which is placed a copper worm. The furnace is built on the central pan, the fire gases passing through the two tubes of this pan, and, further, through the tubes of the smaller closed pans to the right and left of it. The cold mother liquor is pumped into the condenser, when it becomes heated by the steam evolved from the pans. From the condenser it is run into the closed pans, where it is concentrated to a point just below that at which the common salt contained in it would separate out. At this point of concentration it is run into the open central pan, where the evaporation is completed.

The drying of the chloride of potassium is carried out in most of the factories in calcining ovens. Some of the works, however, have adopted a mechanical drying apparatus. This consists of a circular cast-iron plate, enclosing a series of pipes cast in the form of a coil. The plate is surrounded by a sheet-iron border. A stirring arrangement, consisting of a shaft with double arms, to one of which is attached scrapers, to the other rollers, revolves slowly, and continually turns over the salt and grinds it to a very fine powder. The apparatus is heated either by waste or high pressure steam. When the salt is sufficiently dry, the position of the scrapers is altered, the salt is pushed out through a door in the side, and falls into bags held under it. One apparatus is capable of delivering 2½ to 3 tons of dried salt into bags in twenty-four hours, at a cost of 1*s.* per ton.

As to the cost of production of chloride of potassium (known commercially as muriate of potash), taking the price of the raw material at 10*s.* per ton, and containing 16 per cent. chloride of potassium (one-fifth of which is lost during the process of manufacture), then, for the production of 1 ton of 80 per cent. chloride of potassium 6¼ tons of raw material would be required—

	£	*s.*	*d.*
At a cost of	3	2	6
For wages	0	12	0
Fuel	0	15	0
Repairs, packing, etc.	1	0	0
Making a total of	5	9	6

In the year 1880 a committee was formed by the owners of all the mines, or their representatives, to regulate the price of the raw material, and also the quantity that should be worked, the object being to keep the demand for the manufactured product in advance of the supply, and thus benefit the manufacturers. The price and output of the raw material are settled every three months, and a certain fixed quantity apportioned to each factory according to its size.

Private enterprise, however, is threatening the stability of this arrangement, and it is doubtful whether it will remain in force much longer. An English company in Aschersleben, near Stassfurt, has successfully sunk a shaft into the potash deposits, and has erected large works for the production of chloride of potassium, etc. The new Stassfurt Mining Company, one of the mines included in this arrangement, is, in anticipation of a change, erecting plant sufficient to consume 600 tons of its own raw material daily. Under these circumstances the price of chloride of potassium can scarcely be maintained so successfully as heretofore. Manufacturers indeed are anxiously looking out for sources of profit which would make them independent of the production of chloride of potassium.

The mineral kainite, which has hitherto been almost exclusively used as a fertilizer, is now attracting more attention as raw material for the production of the double sulphate of potassium and magnesium, a salt identical in composition with the very rare mineral schönite.

Between the years 1878 and 1882 no less than twenty patents were obtained for the working of kainite, but of these twenty processes only three have been successfully repeated on a manufacturing scale. Artificial schönite is in great demand as a fertilizer, also for the manufacture of sulphate of potash and potash alum, and realizes a comparatively high price.

The first of these processes, patented by Messrs. Botscher and Bruniyes, is worked by the United Chemical Company. The second, patented by my esteemed friend Dr. Precht, is worked by the New Stassfurt Mining Company, with which he has been so long and honourably connected. The third, by Dr. Dupré, of Stassfurt, and myself, has been in successful operation during the last three years at the works of the Stassfurt Chemical Company. Time and the inexorable law of the survival of the fittest will ultimately determine which of these three processes is the best.

There are many other matters connected with Stassfurt to which I have only time to refer, such as the future development of the soda manufacture by the ammonia-soda process, and the further treatment in Stassfurt of some of the manufactured products which, if I enter into at all, must form the subject of a future paper.

As regards the influence of the Stassfurt industry on allied manufactures in this country, doubtless many saltpetre makers have suffered from German competition, owing to the development of Stassfurt; and it is very well known that the manufacture of carbonate of potash is now almost entirely in the hands of the Germans.

After the learned and eloquent paper by our chairman, Mr. Weldon, which we heard not long ago, there is nothing left to be said with reference to the influence of Stassfurt on the alkali trade, though perhaps there are still some who may differ from him in his sanguine expectations. However that may be, the interest which attaches to Stassfurt salts and their treatment may serve, I trust, as an apology for the length of this paper.

So far, then, I have completed my task, viz., the attempt to give you an account of the Stassfurt salts and their mode of treatment. I esteem it an honour to have been requested to do this by our Secretary, Mr. Tyrer, and I have endeavoured to accomplish it to the best of my ability.

Review.

A Manual of Chemical Analysis: as applied to the Examination of Medicinal Chemicals.* A Guide for the Determination of their Identity and Quality, and for the Detection of Impurities and Adulterations for the use of Pharmacists, Physicians, Druggists, Manufacturing Chemists, and Pharmaceutical and Medical Students. Third Edition. Thoroughly revised and greatly enlarged. By Frederick Hoffmann, A.M., Ph.D., and Frederick B. Power, Ph.D.

Following on the heels of the recent Pharmacopœias of the United States and the German Empire, the third edition of this American work on the analysis of medicinal chemicals appears in a revised and enlarged form. The volume opens with a description of the simplest operations employed in analytical work, illustrations being copiously interspersed throughout the text. From this chapter the uninitiated may hope to gather some useful hints, though we cannot refrain from expressing our conviction that it has no legitimate *locus standi* in a manual devoted to an account of the processes of chemical analysis rather than to an explanation of first principles.

Directions for the preparation of reagents follow, the list being unusually lengthy, while a form of apparatus for the generation of sulphuretted hydrogen, though not original, deserves a passing notice.

Instruction upon a systematic course of chemical analysis constitutes the succeeding chapter, in which special attention is directed to what is designated the *dry method.* The scheme for the examination of solutions includes tests for the detection of such rare metals as palladium, uranium and molybdenum. The negative radicals might, we opine, have had a little more thought bestowed upon their arrangement so as to render their study more systematic. Here again we venture to affirm that the directions relating to the preparation of test solutions, and the action of reagents upon the respective groups of metals, belong essentially to an educational treatise which necessarily deals with the fundamental truths of chemical science. Surely such fundamental facts have already been acquired by those for whose special benefit the work before us has been compiled. Thirty pages are devoted to a description of the apparatus and processes used in volumetric analysis, illustrations of the former being inserted. The methods of preparing the usual standard solutions are supplemented by equations expressing their reactions and the corresponding equivalents of the substances estimated by their use. It is to us a matter of surprise that new developments of this simple and rapid method of quantitative determination find no place here. No reference is made to the estimation of phosphoric acid by uranium salt or of the much approved and reliable process of determining cyanogen compounds by mercuric chloride. Saccharimetry by Fehling's solution is treated in a succinct manner. A special feature in this edition is the care which has been exercised on the article on the alkaloids. It comprises a description of their general characters, the systematic separation and recognition of the more important ones, and allied principles. It cannot fail to commend itself to all who may require from time to time to determine the identity or test the purity of an alkaloidal substance.

The second part of the volume contains matter of considerable importance, interesting in varying degrees to the pharmacist, the manufacturing chemist and the commercial analyst. In it the chief medicinal chemicals and their salts are treated of in alphabetical order. The name of each medicament is given in Latin and immediately beneath it appear its German, French and Spanish synonyms. In the case of chemicals having a definite

* London: J. and A. Churchill, 1883. Royal 8vo. Pp. i.-xiv., 1-624. 16*s*.

constitution their formulæ are noted and their molecular weights affixed. Their physical characters are given at length, and not only are the crystallographic structures of solids described, but, in many instances, a woodcut of the perfect crystal is figured. In hydrated salts the amount of water of crystallization is stated, and what is of less practical advantage, the solubility of the majority of substances in various media is supplied. In not a few cases the list of impurities will be held to be too comprehensive, if not, indeed, superfluous. For example, under hydrargyrum ammoniatum, in addition to the usual impurities of mercuric and mercurous chlorides, there are enumerated plumbic carbonate and chloride, calcium carbonate, zinc and magnesium oxide, fusible white precipitate and starch, which would imply fraud rather than probable impurity. In like manner, under quinine sulphate, we find mention of stearic acid and mannite and an examination of our strychnine is to extend to the search for "cinchona alkaloids" and "cinchonine." On the contrary, we find no reference to tellurium as an impurity in bismuth salts, nor are we warned to test our cream of tartar for traces of barium.

No less a space than that occupied by one hundred pages is devoted to a consideration of the acids. The tables of strengths corresponding to various specific gravities and directions for dilution when it is desired to obtain a weaker acid of certain strength constitute an addition which will be highly appreciated. The chief published methods of opium and cinchona analysis are inserted and the characters of the official alkaloids and their salts are explicitly described. The number of medicinal chemicals which have received recognition in this volume is large, embracing such substances as menthol, pilocarpine, curarine and resorcin. By the insertion of medicaments whose introduction into therapeutics is comparatively new we recognize on the part of the authors a laudable effort to keep pace with the requirements of medicine and pharmacy. We trust, however, we shall be acquitted of any desire to be hypercritical if we refer to the number of times certain illustrations occur. Why the simple operation of testing for nitrates, why a graduated jar, why a test tube containing a little zinc, should be figured numerically into teens, baffles our powers of imagination. During a careful perusal of the book, we confess to having experienced some feeling of weariness at beholding these oft recurring illustrations. Need we remark that we are strongly of opinion that, in many instances, these illustrations might have been omitted without any disparagement to the neatly printed volume.

We congratulate the authors on the appearance of the third edition of their work, published for the first time in this country. On the whole it is an admirable compilation and the information it undertakes to supply is both extensive and trustworthy. The selection of processes for determining the purity of the substances of which it treats is excellent and the description of them singularly explicit. Moreover it is exceptionally free from typographical errors. We have no hesitation in recommending it as a useful book of reference to those who are engaged either in the manufacture or the testing of medicinal chemicals.

An Apprentice (who should have sent his name and address).—See an article in the *Pharm. Journal*, [3], vol. xii., p. 997; or the chapter on the subject in Proctor's 'Practical Pharmacy.'

Junior.—Powder the gallic acid, then add the sulphuric acid and afterwards the water. No heat should be applied.

J. F. Giles.—(1) *Origanum vulgare*. (2) *Euonymus europæus*. (3) *Rhamnus Frangula*.

F. C. S.—Apply to the Registrar under the Dentists Act, 299, Oxford Street, W

S. G.—We have been unable to find the receipt you refer to.

Battley's Liquor Cinchonæ.

Sir,—The appended extract from my note-book of observations made more than a year ago, without any idea of publication, may assist Mr. Mee if he should feel disposed to accept the suggestion that has been made to him to pursue his investigations into the merits of Battley's liquor cinchonæ further than his recent letter discloses.

I may say that at the period referred to I examined most of the cinchona preparations of the liquid extract type, and found that Battley's contained by far the largest percentage of alkaloid; but it may fairly be doubted whether something like 3 per cent. is a satisfactory percentage of alkaloid in a preparation professing to represent eight times its relative weight of finest cinchona bark. There are, however, other important conditions demanded from a good liquid extract which are too obvious to need enumeration, and it would seem from my notes that the process of "pegging away by steeping and boiling (?)" has produced changes in Mr. Battley's product which it is a well-understood object of pharmaceutical manipulation to avoid.

"*Note to Examination of Battley's Liquor Cinchonæ by "Prollius' Method.*

" . . . The decanted liquor (ether, ammonia and spirit) was allowed to evaporate spontaneously in a porcelain dish, leaving impure mixed alkaloid as residue. The residue was so largely contaminated with black resinous-looking matter that it was out of the question to estimate it as 'impure alkaloid.' It was therefore redissolved in weak hydrochloric acid, filtered and transferred to separating bottle and shaken with chloroform and caustic soda in excess, and left till the morrow to clear. The chloroform solution was dark in colour and not perfectly clear; it was drawn off and the chloroform distilled; the residue was black and obviously unfit to be weighed as alkaloid. It was, however, weighed, and gave as result 2·638 per cent. (or in reference to volume of liquor operated upon 2·923 per cent.) of total impure alkaloid. The last-mentioned residue (impure alkaloid) was treated with solution of oxalic acid which dissolved out alkaloids, but left a black residue soluble in hydrochloric acid. The black residue was very unlike any extractive which might be expected from cinchona."

N.B.—The actual percentage of alkaloid was estimated by Carle's process, the above being of course unreliable.

Richard W. Giles.

J. J. B. Woods.—(1) *Artemisia vulgaris*. (2) Probably *Atriplex angustifolia*: fruiting specimens only should be sent, with the stem and radical leaves attached. (3) *Eupatorium cannabinum*. (4) *Polygonum aviculare*.

"*Cymro*."—(1) *Ononis arvensis*. (2) *Chlora perfoliata*. (3) *Origanum vulgare*. (4) *Crepis paludosa*. (5) *Hypericum montanum*. (6) *Verbena officinalis*. (8) *Knautia arvensis*. (9) *Epilobium hirsutum*. (10) *Epilobium montanum*. (11) *Melampyrum sylvaticum*. (12) *Helianthemum vulgare*. Please not to send more than six specimens at one time in future.

Herbalist.—(1) *Trifolium arvense*. (2) *Equisetum arvense*. (3) *Ononis arvensis*. (4) *Clematis Vitalba*. (5) Too imperfect; probably *Athyrium Filix-fœmina*. (6) *Lastræa Filix-mas*.

J. Hicking.—The leaf is insufficient for identification but it probably comes from a *Chamærops*.

F. W. Bates.—"Zittmann's Decoction" is a compound decoction of sarsaparilla. It is prepared of two different strengths, the stronger containing calomel and cinnabar, which are left out in the weaker. The formulæ, which are too long for extraction, may be found in Gray's 'Supplement.'

R. A. Hoyle.—(1) *Sisymbrium officinale*. (2) Not found. (3, 4, 5) Named correctly. (6) *Parietaria officinalis*.

COMMERCIAL NITRITE OF SODA.

BY PETER MACEWAN.

The purity of nitrite of soda as found in trade at the present time has been discussed in this Journal.*

The method of preparing this salt most familiar to pharmacists is that of the British Pharmacopœia, 1864, namely, by fusion of a mixture of nitrate of soda and charcoal. The investigations of Howard, Miller and Warrington† showed that the product so obtained is a mixture of carbonate, hydrate, nitrate and nitrite of soda, the latter in varying quantity, never exceeding 42 and generally less than 25 per cent. To obtain a better article Mr. Howard suggested that the complex mixture should be dissolved and fractionally crystallized, the nitrite crystallizing after the carbonate and nitrate. This undoubtedly yields a purer nitrite, but it does not get rid of the principal objections to the charcoal process, namely, somewhat uncontrollable deflagration and formation of a large percentage of carbonate. By the employment of other deoxidizing agents, such as lead or copper (in a fine state of division), these objections are overcome, and a product obtained having a higher percentage of nitrite associated with nitrate and a small proportion of hydrate. This, by fractional crystallization, will yield a salt corresponding to Mr. Ekin's description, that is, containing "98 per cent. of real nitrite, the 2 per cent. of impurity consisting chiefly of moisture."

Previous to the communications of Dr. Hay and Mr. Ekin I had had opportunity of examining several commercial specimens of the salt, and since then have obtained a number from different parts of the country. The following table shows the results of the examination of twelve of these, which I take to represent fairly the commercial article:—

No.	Characters.	$NaNO_2$. Per cent.	Na_2CO_3. Per cent.
1	Large transparent crystals, very moist	0·011	35·5
2	"Old stock," small crystals, brownish	0·028	29·66
3	Large transparent crystals, very moist	0·945	32·6
4	Fused mass, white	9·6	27·34
5	White and granular, very moist	28·4	—
6	White and granular, dry . .	84·14	—
7	Small crystals, white, moist .	92·5	—
8	Small crystals, brownish, moist	93·65	—
9	Small crystals, white, moist .	95·1	—
10	Small crystals, brownish, moist	95·83	—
11	Small crystals, white, dry . .	97·21	—
12	Small crystals, white, dry . .	98·5	—

Nos. 1 to 3 are evidently the first crop of crystals from a solution of such a specimen as No. 4, which, itself, answers the description of the 1864 Pharmacopœia preparation. Nos. 5 and 6 contained undecomposed nitrate and the former much water. The others contained water in varying proportions and but mere traces of other impurity, the higher percentages of Nos. 11 and 12 being accounted for by the fact that they were examined as received from the makers, while the others had been in stock for a few months.

The percentages in this case were determined by decinormal permanganate of potash solution, which gives good results with care and some practice. A very good plan is to fill a burette with a solution of the salt under examination (1 gram in 100 c.c. distilled water is a convenient strength) and drop carefully into a flask containing 10 c.c. permanganate and an equal volume of sulphuric acid (1 in 4) until a pale pink colour is struck, which should not disappear within thirty seconds. The quantity of nitrite solution being noted, the titration is repeated twice, it being merely necessary to add 10 c.c. of permanganate to the contents of the flask each time. The mean of the three estimations is taken for calculation, 10 c.c. of the permanganate solution being equivalent to ·0345 gram $NaNO_2$. Old stock of this article should be looked over. The fused "nitrite of soda" of the 1864 Pharmacopœia (which I understand is not unfrequently sent out by wholesale houses) should certainly not be dispensed, and as the crystalline and granular varieties may be either good or bad, their strength should be ascertained and stock replaced if necessary.

MATE OR PARAGUAY TEA.*

BY DR. THEODORE PECKOLT.

This plant, which belongs to the holly family (Ilicineæ), has several names in different parts of South America. In the Guarani language it is called *Caá*, which is the Indian word for leaf. The prepared leaves were named by the Spanish "yerba" (herb), and the infusion "mate"† from the native name for the vessel in which the tea is made, and the drug is now generally known as mate in Brazilian commerce, although the Spaniards call it "yerva mate" or "yerva de palos." The name "congonha" has been said by some writers to be applied to mate, but this is an error, for the Brazilians understand by the names "congonha mansa" and "congonha brava," other trees belonging to the same natural order, which are used as a substitute for mate when it is not easily procurable.

The plant was first briefly described by St. Hilaire, in 1822, when he gave to it the name *Ilex paraguariensis*, which he altered in 1826, to *Ilex Mate*, subsequently publishing the first name again in 1833 and this is now adopted in the 'Flora Brasiliensis.' In 1824 the plant was described in detail by Lambert, under the name of *I. paraguensis* and the plant illustrated from specimens obtained from the Jesuit Missions. The synonyms stand as follows:—

Ilex paraguariensis, St. Hil.; *I. Mate*, St. Hil., *I. paraguayensis*, Hooker, fil.; *I. paraguensis*, D. Don.; *I. paraguariensis*, *a*, *obtusifolia*, Mart.; *β*, *acutifolia*, Mart.; *Cassine Gongonha*, Raben.; *C. Gouguba*, Guibourt; *Chomelia amara*, Vell.

The mate plant attains the height of an apple tree, becoming even larger in favourable situations, but when cultivated and deprived from time to time of its leaves, it remains small and forms a mere bush. The leaves are shortly stalked, simple, wedge-shaped, obovate or elongate-lanceolate, toothed, dark green above, paler beneath, shining, of leathery consistence, 1 to 3 inches long, and ½ to 1½ inch broad. The flowers are axillary, situated on one to three times forked peduncles, white, and of similar size to those of the common holly. The calyx consists of four nearly orbicular sepals with a four-parted corolla and four short stamens, the ovary being crowned with a four-

* Abstracted from a paper in the *Zeits. d. allg. öster. Apot.-Verein.*

† The word is not accented, as sometimes written.—T. P.

lobed stigma. The fruit is red and of the size of a pepper-corn, containing four seeds enclosed in a slightly glutinous pulp, but often one seed only is developed. The home of the Paraguay tea plant is said by Martius to lie between 18° and 30° S. latitude, but the district in which the tree grows most luxuriantly is between 21° and 24° S. latitude in the watershed of the Paraguay river on the west, and in that of the Parana on the east, and it is here in a zone between the Serra Amambuhy on the south and the Serra Maracajú on the north that the best and most highly prized mate is prepared.

How long the South American Indians had been in the habit of using mate is not known, but when the Spaniards seized the provinces on the rivers Paraguay and Uruguay they found this custom prevailed there exactly as first mentioned in the writings of Azara, who stated that the tree grew wild in different parts of Paraguay. In proof of the high estimation in which it was held by the Indians it may be mentioned that the name " caa," which signifies in the Tupi language a tree or plant, was given by way of distinction to mate, that being the tree valued above all others. The use of mate does not appear, however, to have extended to extra-tropical districts, but to have been confined to the more intelligent tribes known now under the name of Guarani Indians. Nevertheless, when these people were driven further north by Europeans, they do not appear to have carried the use of the drug with them, probably thinking it not worth while to obtain it from a distance and from a hostile people when they found a substitute close at hand in the Guarana plant.

The extensive use of mate in South America at the present time is probably due in great measure to the Jesuits, who encouraged its use, finding that it restrained the desire of the Indians for spirituous drinks, while its cultivation, collection and preparation gave employment to converted Indians and brought wealth to the order. In the Jesuit Republic, the Indians were not paid in money but in produce; 4 lbs. of meat, a definite amount of Indian corn and 1 oz. of mate were allowed to each family.

After the expulsion of the Jesuits, the preparation of mate was continued in the Paraguay Republic under the administration of the Dictator Francia and his successors, until the Dictator Solano Lopes was killed in battle with the Brazilians in 1870. An overseer was appointed over the work who also was paid in kind, receiving for each aroba of the tea natural produce of the value of $\frac{1}{5}$ ounce of gold. Since 1870 there has been free trade in the article, which renders an increase of the trade very desirable. At the present time mate is used only by about 12,000,000 of people, and the consumption amounts to about 8,000,000 pounds.

It has been stated that mate is not prepared solely from *I. paraguariensis*, St. Hil., but that the leaves of other species are mixed with it.

In 1842, Sir W. J. Hooker published in the *London Journal of Botany* (vol. i., p. 30) an exhaustive account of yerba mate, together with the characteristics of the different varieties which he considered identical with *Ilex paraguariensis*. This paper strengthened the previous opinion of Miers that probably more than one species was used in the preparation of the tea. The investigations made by Miers and the monk Leandro, Director of the Botanical Gardens in Rio Janeiro, confirmed by Bonpland, indicate that six different species are used for the purpose :—1. *Ilex theezans*, Bonpl., growing in Paraguay, Entre Rios and Brazil; 2. *Ilex ovalifolia*, growing in the neighbourhood of Rio Pardo; 3 *Ilex amara*, Bonpl., on the mountains of Santa Cruz and in the forests of the Brazilian province of Parana; 4. *Ilex crepitans*, Bonpl., in the interior of Santa Cruz and the banks of the Parana river; 5. *Ilex gigantea*, Bonpl., on the banks of the Parana river. This is the " caa-una " of the Guaranis. 6. *Ilex Humboldtiana*, Bonpl., in the province of Rio Grande do Sul. This is the "caa-unina" of the Brazilians. The last four species, more especially *I. amara*, yield the "caa-chira" of the Guaranis and the "caa-una" of the Brazilians. Martius, however, in the 'Flora of Brazil,' states that in the central districts of Paraguay, where the *I. paraguariensis* is especially abundant, only the leaves of this species are used; in other districts the various species of *Ilex* are similarly employed.

It is certain, however, that *I. paraguariensis* is the only species in cultivation, but this is carried on to a very limited extent as the wild plant is still abundant. The Jesuits planted the tree because they found that under cultivation the leaves had a milder and more pleasant taste. For cultivation the seeds are carefully freed by washing from the glutinous matter in which they are imbedded, without which treatment they would not germinate, this office being probably performed in a natural state by birds, since the Indians believe that the seeds will not germinate unless they have been voided by birds. The young plants are taken out of the hotbed when about 6 inches high and planted out about 12 to 15 feet apart, in a damp, somewhat marshy ground, so as to allow of a small trench being made around the plants in which water can collect. They must also be grown under the trees which afford shade, as the young plants are easily killed by a strong sun. When they are about 3 to 6 feet high some of the shade plants are removed, and in four years the leaf harvest can be begun. The young trees should not, however, be entirely deprived of their leaves lest they should not be able to recover. In the seventh year they will yield 30 to 40 kilos of leaves. It is calculated that on 220 square metres of land one thousand six hundred trees can be grown, yielding on an average 35 kilos of leaves per tree, or about 25,454 kilos of leaves, valued at 190,000 marks per 100 square metres. The cultivated plant remains a small bush and never reaches the stature or size of the wild tree. The cultivation of mate has been carried out with much success in the province of Parana by Dr. E. Westphalen, and it promises to be successful in the Dutch colony of S. Leopoldo in the province of Rio Grande do Sul, where the plant grows luxuriantly.

The tree has been planted in the Cape of Good Hope and seems to succeed well there, as well as in Spain and Portugal. The quality of Paraguay tea depends upon the time of year in which it is collected, the leaves possessing most aroma when the fruit is nearly ripe. In the Argentine Republic and in the Brazilian province of Rio Grande do Sul the leaves are collected from February to the end of July. The new shoots are put forth in August, but at that time it would ruin the trees to gather the leaves. In the forest of the Brazilian province of Parana and Santa Catherina the harvest is collected from March to the end of September. In Paraguay it begins in December and continues till August. About a month beforehand the collectors set out in caravans with their wives and children into the forests where the mate trees are abundant, and make their encampment.

The first operation is to prepare a torrefier, which is made in the shape of an arbour. The twigs are cut off from the branches and slightly scorched by drawing them quickly across the fire. The twigs are then collected into bundles suspended over the torrefier, a small fire of dried wood being kept alight beneath. In about two days the drying is completed, the ashes are removed, and in the spot where the fire was an ox-hide is spread out, on which the leaves are beaten from the twigs with a wooden blade. The dried leaves are then powdered and packed in wooden cases made out of hollowed trunks of trees.

In the province of Parana the leaves have lately been dried in large wrought-iron pans, in the same manner as Chinese tea, or in specially constructed ovens in which they can be prepared so as to retain more aroma; they are then powdered by machinery and sifted: this kind of mate obtains a better price.

Another form in which the leaves are prepared is by carefully separating them from the stalks and twigs and roasting them, but this is not so much esteemed as the powder, except in Chili, where the leaves are preferred.

In the South American Republic and the Brazilian province of Rio Grande do Sul, mate is packed in serons of ox-hide holding 30 kilograms, and in half-serons, containing 15 kilograms; this packing gives to the mate a disagreeable flavour which detracts from its value.

In Parana it is packed in cane baskets; these are lined with dried grass, called Jacaes, and contain 50 to 60 kilograms. The mate in leaves is here sold at 280 to 290 reis (about 56 pence), powdered mate is sold in thick and better-woven cane baskets, containing in a half-seron, 15, and as a seron, 60 kilograms, the price being 10 to 12 per cent. more than the leaves.

In the Spanish Republic three different sorts are sold under the following names:

1st. Caá-cuy, or Caá-cuys: these are the new leaves of the scarcely developed shoots. They are of more delicate texture, and of a yellowish colour. They possess an agreeable and pleasant flavour, but are seldom met with in commerce.

2nd. Caá-mirim. This was the chief product in the time of the Jesuits, and consists of the leaves carefully separated from the twigs and stalks, the mid-rib of the leaf being also removed. This kind is chiefly esteemed in Peru, and principally exported there by the Brazilians. It is called Herva mansa.

3rd. Caá-guacu, or Caá-una, or Yerva de Palos, is the most inferior kind, consisting of the large and old leaves with the twigs and fragments of wood, and possessing a strong and bitter flavour.

In Rio Janeiro two sorts are known to commerce, mate in leaf and mate in powder. In order to test the quality of mate, the merchant takes a small quantity in his hand and blows upon it. If the greater portion is blown away he considers that it has been heated too much and thus deprived of its strength. If it is not easily blown away it is then considered of good quality.

Mate has been the subject of several analyses. In 1836, Trommsdorff analysed mate and found tannin, two resins, extractive matter, and a substance which he believed to be an alkaloid, but he possessed too little material for complete investigation.

In 1843 Stenhouse found in mate an alkaloid and proved that it was identical with caffeine.

In 1850, Dr. Rochleder investigated Paraguay tea and found the reactions of mate-tannic acid to be identical with those of coffee-tannic acid.

Lenoble, who, as well as Dr. Rochleder, supposed mate to be produced by *Psoralea glandulosa*, named the crystalline active principle he obtained from it, "psoralein."

He also found in it wax, albumen and volatile oil.

According to Dr. Byasson, mate contains as much caffein as the best Chinese tea. The variety which he experimented upon was caá-guacu. He found also a viscid substance resembling birdlime, soluble in ether; this he considered to be a fatty body of the nature of a compound ether whose alcohol was allied to cholesterine. His analysis was as follows:—

	Grams.
Caffeine	1·850
Substance resembling birdlime, fat substance and colouring matter	3·870
Complex glucoside	2·380
Resin	0·630
Mineral matter	3·920
Malic acid	Not estimated.

Robin has examined several different kinds of mate. The amount of caffein in young leaves dried without special care was 0·02 to 0·03 per cent.

Mate prepared by the Indians and containing twigs and fragments of fruit yielded 0·16 per cent., and mate from the Mission of the Province of Corrientes, 0·14 per cent. The peculiar tannic acid, which Dr. Byasson did not find, varies between 1 per cent. and 1·6 per cent. The ash of young leaves varies from 0·12 to 0·2.

Professor A. W. Hoffmann, of Berlin, found 0·3 per cent. of caffeine. The average of the published analyses indicates about $\frac{1}{2}$ per cent. of caffein, that of Indian tea being 2 per cent. The value of mate, as in the case of tea, depends not merely upon the caffeine but also upon the tannin and aromatic principles. He considered the tannin to be identical in every respect with that found in tea.

The aromatic principle has not been isolated, but by dry distillation a volatile oil is obtained, which belongs to the phenol group and is soluble in alcohol.

In 1877 the mate-tannic acid was examined by Dr. Pedro N. Arata, who found that the tannin of mate, while analogous to that of coffee, was not identical. The chief differences noticed by him are as follows:—Lime water gives with the coffee-tannic acid a small precipitate soluble in excess, but an abundant insoluble precipitate with the tannin of mate. This, however, does not hold good with all samples of mate, the precipitate being sometimes soluble in an excess of the tannin. Coffee-tannic acid gives by dry distillation pyrocatechin, while the tannin of mate yields in addition to pyrocatechin the isomeric body resorcin.

Coffee-tannic acid is soluble in 52·84 vol. of alcohol, while mate-tannic acid requires 73·66 vol.

Dr. Arata considers that coffee-tannic acid may be regarded as dioxyparacinnamylic acid, whilst mate-tannic acid must be classed in the group of oxyphenylpropionic acid.

Soubeiran and Delondre state that mate contains the same essential constituents as the coffee leaf, and in greater amount than the coffee seeds, which I can confirm after numerous experiments with large and small quantities.

In the years 1860 to 1865 I analysed mate and Congonha leaves. My analyses were made with fresh leaves of the *Ilex paraguariensis* from the Orgel Mountains in Neufreiburg, and roasted and unroasted leaves from the province of Parana.

In the air-dried leaves from the Orgel Mountains I found the following substances in 1000 grams.

	Grams.
Stearoptene	0·021
Volatile oil, extracted by ether	0·099
Fat and wax	19·800
Green colouring matter	10·900
Chlorophyll and soft resin	20·966
Brown acid resin	48·500
Caffein	6·398
Bitter extractive matter	2·033
Sugar	39·266
Extractive matter and organic acids	8·815
Mate-tannic acid, pure	27·472
Mate-viridic acid, crystallized	0·024
Albumen, organic acid, inorganic salts, dextrin, etc.	47·660
Moisture	166·660
Cellulose and lose	601·386

In 1000 grams of air-dried little twigs of the *Ilex paraguariensis* from Neufreiburg I found:—

	Grams.
Green soft resin and chlorophyll	9·400
Brown acid resin	19·700
Caffein	2·579
Mate-tannic acid and extractive matter	30·000
Extract, cellulose and water	938·321

In 1000 grams of air-dried leaves from Parana, from which the roasted mate is prepared, I found the following substances:—

	Grams.
Stearoptene	0·019
Volatile oil, obtained by ether	0·179
Fat and waxy substance	18·800
Green colouring matter	10·800
Chlorophyll and soft resin	51·200
Brown acid resin	84·500
Caffein	16·750

	Grams.
Aromatic substance	2·500
Mate-tannic acid, pure	44·975
Mate-viridic acid, crystallized	0·025
Extractive matter	65·130
Saccharine extractive matter, sugar	6·720
Albumen, salts, dextrin, etc.	36·102
Moisture	104·600
Cellular matter	557·700

In 100 grams of commercial mate from Parana I found:—

	Grams.
Volatile oil, obtained by ether	0·026
Caffein	5·550
Chlorophyll and soft resin	6·102
Brown acid resin	25·500
Mate-tannic acid pure	16·785
Pyromate-tannic acid	1·465
Mate-viridic acid, crystallized	0·024
Extractive matter	16·610
Caramel-like extractive matter	1·370
Salts, dextrin, etc.	18·189
Cellular matter and moisture	908·379

The ash of mate analysed by Dr. Busse and Herr Riemann was found to contain potassium, sodium, magnesium, oxide of manganese, calcium, aluminum, iron, phosphoric acid, sulphuric acid, carbonic acid, chlorine, silicic acid; but the analyses vary so much in different samples as to lose some of their value.

I found in leaves of mate gathered in Neufreiburg—

	Per cent.
Oxide of manganese	8·958
Sodium	10·062
Potassium	14·615

Whereas these were not found at all by the above-mentioned analysis in leaves obtained from Rio.

THE ACTION OF CERTAIN VEGETABLE ACIDS ON LEAD AND TIN.*

BY FRANCIS P. HALL.

The enormous and continually increasing use of canned goods—fruit, vegetables, meat, etc.—has led to the discussion, on sanitary grounds, of the possible injurious effect of the material of the can on its contents; and among other chemical questions is that of the effect of various vegetable acids upon the material of the cans, *i.e.*, upon the can itself and upon the solder which may be exposed on the inside. The fear also has arisen lest the tin-plate itself of which the cans are made should, for the sake of greater cheapness, be made not with pure tin, but with an alloy of lead and tin.

The following paper contains the results of experiments on the action of certain acids on tin and on alloys of tin and lead, and also the results of some investigations as to the quality of the tin plate and tin foil in actual use as envelopes for food products.

Action of Vegetable Acids on Alloys of Lead and Tin.

One of the most important things to be considered in investigating the power of an alloy to resist corrosion is the electrical relation of the metals which compose it. Lead and tin are so nearly alike in this respect that their relation to each other may be reversed in different liquids, or even in the same liquid under different circumstances. On this subject chemical literature contains many and quite discordant statements. It seems, however, to be fully established by the experiments of Weber that ordinary vinegar will dissolve lead from an alloy of lead and tin containing only 5 per cent. of lead, and further, that from a dilute acidulated solution of acetate of lead, lead is precipitated by an alloy containing as little as 5 per cent. of tin.

In the following investigation I wished to ascertain quantitatively the action of several of the more common vegetable acids, all quantitative experiments that I had seen being made with acetic acid only.

* *American Chemical Journal.*

To ascertain definitely the effect of alloying on the corrosion of the metals, the amount of lead or tin dissolved when pure must be compared with the amount dissolved, under the same conditions, from an alloy exposing the same surface of the metals in question. To make the experiment, as is usually done, with equal sized pieces of pure metal and alloy is not fair, if we consider the action to be proportional to the surface of metal exposed, because then the united surface of the two pieces of pure metal is twice that of the alloy and the surface of either metal exposed in the alloy is less than that exposed by the piece of pure metal.

To overcome this difficulty I proposed to proportion the size of the pure metal plates according to the composition of the alloy. In order to proportion them more easily and to have them of a size readily comparable with one another, I took into account the specific gravity of the metals in making the alloys. Hence, barring the unequal contraction of the metals on alloying, I had alloys exposing a known surface of lead and tin. I could now expose an equal surface of pure metal to the same acid under the same conditions and compare the action, thus getting a fair idea of the effect of alloying the metals, as well as the action of the acid on a known surface of pure lead or tin.

I made after this plan three alloys — one with equal parts of lead and tin, one with an excess of lead, and one with an excess of tin. These were all I had time to experiment with, but the researches of Weber show that, for acetic acid at least, the action on the alloys increases quite regularly as the proportion of lead increases; therefore the action on alloys containing lead and tin in different proportions than those I took can be inferred with fair accuracy by interpolation.

The alloys were made from pure lead and tin, well stirred when melted, then cast in thin sheets in iron moulds. Afterwards these sheets were rolled into thin strips and trimmed to the size desired. Strips of pure lead and tin were made at the same time. The tin used was Banca tin, containing 99·78 per cent. of tin, a trace of lead and a trace of copper.

For acids I used a solution of glacial acetic acid in distilled water, which, on titration with a standard solution of ammonia, proved to have a strength equal to 5·75 per cent. of acetic acid; also solutions of crystallized tartaric and citric acids, which neutralized the same amount of ammonia.

The tartaric and citric acids contained, as they always do, a trace of lead, but the amount was much too small to appreciably influence the results.

Strips of the alloys 1·2 inch wide and 12 inches long were cut out, exposing, therefore, counting both sides, 28·8 square inches or one fifth of a square foot. Pieces of pure lead and tin were taken of the same width, but varying in length to suit the composition of the alloy to which each corresponded. These strips of metal were rubbed until perfectly bright, washed with a little dilute alcohol, heated in a drying closet, and when cool weighed. Immediately after weighing they were put into separate beakers each containing 200 c.c. of acid. The long strips were coiled and kept off the bottom of the beaker by a ⟍⟋ of glass rod. In each case the liquid covered the metal by more than an inch, so that the air did not take part directly in the action. Each beaker was covered with a watch glass.

After standing for two weeks in a place where the temperature varied from 25° to 35° Centigrade, the contents of the several beakers were examined. The most notable change was that the acid containing the tin, as well as that containing the alloys, had a decided yellowish tint, while that containing the lead was perfectly clear and colourless. The metal in all cases was more or less tarnished, but the tin much more noticeably so than the lead. Two of the alloys in the acetic acid were sprinkled with little black crystals. These crystals were evidently metallic; they were carefully collected, washed with alcohol, dried and analysed. The result of the analysis is given later. The smallest of the pieces of lead in the tartaric acid was covered with small transparent crystals; these were set aside for further examination. The pieces of tin were covered with a dusty powder, but there was not enough of it to analyse.

When the contents of each beaker had been carefully examined, the strips of metal were lifted out, washed with a jet of water, dried with a soft towel, and, after remaining a while in a drying closet, weighed. The loss of weight served as a rough check on the subsequent analysis of the solutions. Next, the metal in solution was precipitated by sulphuretted hydrogen. The lead caused dense black precipitates, much finer in the tartaric and citric acid than in the acetic. The tin in the acetic acid came down of a dark brown colour, showing the stannous salt, while that in the tartaric acid gave, at first, merely a yellow coloration. After standing some time, however, a flocculent, apparently hydrated precipitate settled out. The same seemed to be the case with the citric acid solutions, but on closer examination an almost transparent precipitate could be seen, and it settled much quicker than in the case of the tartaric acid. These same peculiarities of the precipitates of sulphide of tin were noticed throughout the whole investigation. It was also invariably the case with the alloys that the precipitates in acetic acid were dark brown, while those in tartaric and citric acids were light coloured and flocculent.

After some experimenting I found the best way to separate the sulphides of lead and tin in the solutions was to carefully decant as much as possible of the liquid through a filter, neutralize what remained with ammonia water, add a little yellow ammonium sulphide, and heat; then collect the sulphide of lead on the filter used before. The tin was determined in the alkaline filtrate. The sulphide of lead was converted into the sulphate before weighing; the sulphide of tin into the oxide in the usual manner. In no case was either metal determined by difference.

The results obtained are given in the form of tables.

TABLE I.

Kind of acid.	Surface exposed, in sq. inches.		Percentage composition.		Loss of weight, in grams.	Found in solution, in grams.		Percentage of dissolved metals.		Total amount dissolved (in grams) from

The first two columns of Table I. give the amount of surface of each metal exposed both as pure metal and in the alloy. The last two give the total weight of metal, lead and tin, dissolved from the alloy, and from an equal surface of the same metals exposed in the pure state. But although the surface exposed was the same, the unalloyed metals were exposed to twice as much acid, each being in a separate beaker with 200 c.c. of the acid. This might have been righted by proportioning the acid to the surface exposed, but this did not occur to me until too late. It will be noticed how often the amount dissolved when unalloyed is equal to twice that dissolved from the alloy.

The alloys Nos. 1 and 2 in the acetic acid were the ones on which the small black crystals before mentioned were found. The crystals on No. 1 weighed 0·0970 gram, and gave on analysis 0·0931 gram of lead, or 91·6 per cent. Those on No. 2 weighed 0·0620 gram, and gave 0·0586 gram of lead, or 94·45 per cent. They were evidently, therefore, crystals of lead. This amount of lead might have been considered as having been in solution, but it is not included in the amount given in the tables. Weber* noticed similar crystals in his experiments, and explained their presence by supposing that, at the surface of the liquid where the oxygen of the air and the acid both acted on the metal, so much lead was dissolved that it was precipitated again by the tin of the alloy below the surface. As, in my experiments, the metal was kept entirely covered by the acid, this could hardly have been the case.

The transparent crystals found on the smallest piece of lead in the tartaric acid were nearly, if not quite, insoluble in water. Under the microscope they appeared to be hexagonal, and very much like small quartz crystals. They were found, on comparison, to have the same form as crystals of tartrate of lead. From this and from a few qualitative tests I decided that they must be tartrate of lead. The crystals adhered so firmly to the lead that they could not be removed,—therefore, the loss of weight, as well as the lead in them, could not be determined.

The results of the experiment agree in all essential

* *Dingl. Polyt. Journ'* ccxxxii., 153, 264.

points with those statements which I have found that have been supported by actual experiment. Those statements which would have us suppose that alloying with tin increased the corrosion of lead seem to be founded on the case of some stray tank or pipe, rather than on a well-conducted research. Moreover, it does not appear, as is often supposed to be the case, that the alloy is more acted upon than either of the metals.

It was suggested that the galvanic action would influence more the rapidity of the corrosion than the total amount of metal dissolved; hence that the effect would be more clearly marked at the end of two days than at the end of two weeks, but experiment showed that this is not the case. For this experiment I used only one of the alloys, namely, that containing the most tin: the results are recorded in Table II. While the amount of

action is not exactly proportional to the time of exposure, it is not far from being so in the case of acetic acid, and in the case of citric and tartaric acids it is evident that the action is very slight at first and increases appreciably as time goes on.

In these experiments, although the metal was covered with the acid and the beaker with a watch-glass, the air had more or less free access to the surface of the liquid. To see what effect the air had on the corrosion, and to approach more nearly the conditions of a sealed can, I took some glass stoppered bottles and repeated the experiment in them. I weighed the strips of metal as before and placed them in the bottles, then heated the bottles on steam cups, and while hot filled them with the acid, also heated to boiling to expel any air. The bottles were at once tightly stoppered. As they cooled a few of them leaked a little, but as it was nearly full of liquid very little air could enter. They were put in the same place as in the former experiments, and left for two weeks. On being examined at the end of this time there was evidently much less corrosion than in the case of the corresponding experiments in open beakers. There was no discoloration, and no crystals formed. That the air had been pretty well excluded could be seen from the way the stoppers stuck in the bottles even after they could be turned with ease. The same difference in the character of the precipitates of sulphide of tin was noticed as before.

The results are given in Table III.

The acids used were of about the strength of good vinegar. It would naturally be supposed that less strong acids, such as usually occur in canned goods, would cause correspondingly less corrosion. This does not seem to be the case; an incomplete series of experiments seems to indicate that a dilute acid, if used in sufficient quantities, causes much more corrosion than would be inferred from its strength.

To try now the action on the cans themselves, and also the effect of the solder, I took three cans that had been emptied and put 200 c.c. of acid into each—acetic acid in one, tartaric acid in another, and citric acid in the third. I covered these cans as well as I could by tying two thicknesses of paper over each, but of course they were practically open cans; moreover the acid did not nearly fill them. They would represent, therefore, a can that had been partly emptied and sent away, rather than a fresh one. When examined at the end of two weeks, the tinning up as far as the acid reached was entirely taken off, except in the acetic acid. Th. citric acid had a yellowish colour, and a quantity of white powder was deposited on the bottom of the can. I emptied the acid from the cans and added a few drops of chlorhydric acid, fearing that the organic acid was not sufficient to hold up the sulphide of iron. The addition of chlorhydric acid and a little warming dissolved the white powder in the citric acid, and at the same time destroyed the yellow colour. On passing sulphuretted hydrogen through the solutions, a very large precipitate was obtained. This I filtered off, washed, and treated with ammonium sulphide; the residue was collected on a filter, dissolved in strong chlorhydric acid, and after evaporation the lead was precipitated as sulphate.

The tin was determined in the ammonium sulphide solution. The result was as follows:—

Acetic acid dissolved 0·4178 gram of tin and 0·0117 of lead.

Tartaric acid dissolved 1·0430 gram of tin and 0·0873 of lead.

Citric acid dissolved 0·6828 gram of tin and 0·1559 of lead.

In addition to the lead and tin there was a good deal of iron dissolved.

This shows that corrosion takes place very rapidly after a can is opened, and that a can once opened should be emptied at once. One would have supposed that the acetic acid would have acted more than the others, and it probably would if the conditions in the different cans had been exactly the same. It is probable that more solder was exposed in the cans treated with tartaric and citric acids; at any rate the lead must have come from the solder, as the tin from which the cans were made proved, on being tested, to be free from lead.

On the Quality of Commercial Tin Plate.

Having seen the action of some of the more common vegetable acids on lead and tin, and the alloys of the same, we come to the tin plate itself.

The tin plate used in America is entirely imported, most of it from England. The two principal kinds are "Bright plate" and "Terne plate." Bright plate is, or should be, tinned only with pure tin. It is divided into several grades, according to the thickness of the tinning and the quality and heaviness of the iron which forms the basis, but in all these grades the tinning is supposed to be pure tin. Terne plate, on the other hand, is known to contain large quantities of lead, and is often called lead plate, there being no attempt to pass it for tin, at least by respectable persons.

Tinware and fruit cans are made from bright plate, while terne plate is used altogether for roofing. Of course the boundaries are sometimes overstepped; those who are very particular use bright plate for roofing, and those who are too avaricious may make tin ware out of terne plate. This last, I think, however, is very seldom the case, and the heavy nature of terne plate unfits it for canning.

Knowing these divisions of tin plate, the questions before us now are: Is bright plate, especially that used in canning, always tinned with pure tin? and, How commonly is terne plate used where it will come in contact with food?

I procured some specimens of plate through the kindness of one of the largest importing houses in Boston. These I tested by several methods. With the bright plate, taking small pieces, I could find no lead at all, and only after taking half a square foot did I find a trace. This was no more than would be found in most English bar tin. I now tested a number of cans from various sources, as well as the worst-looking tinware from the so-called five cent stores, but not once did I find enough lead to show an intentional adulteration. Neither have I found any well instituted attack on the character of the tin plate in the United States. A good deal has been said and many suspicions thrown out, but the only statements of analyses that I have seen are in a Board of Health report of a Western State.* The author found lead so invariably in all tin articles that came into his hands that one cannot help suspecting that the methods of analysis were unreliable. He even observes that he found a considerable quantity of lead in what was sold for pure tin—a thing quite possible, it is true, but not likely to happen with dealers to whom a chemist would naturally go for pure supplies.

* 'Mich. Board of Health Report,' 1878, p. 29.

Even if the tin of the can is pure, there remains the solder, which always contains a large quantity of lead, and is used very freely. There remains, also, the fact that the vegetable acids act considerably upon tin itself. There are many published statements as to the presence of tin in canned goods, and the careful inspection of the inside of a can which has contained an acid fruit shows quite clearly in many cases that corrosion has taken place. Moreover, although my experiments tend to show that the amount dissolved when the air is excluded is much less than when open, still it is an appreciable quantity; and if, as seems to be the case, the amount increases with the time, that dissolved from an old can must be considerable.*

The terne plate, which is that most often used for roofing, cannot be considered quite harmless in cases where the water from the roof is used for household purposes. But as the tin roof as well as the whole house is generally covered with a paint containing far more lead than the terne plate itself, it would be absurd to complain while we use white lead to such an extent as at present.

I made a rough analysis of the tinning of terne plate by dissolving it off with chlorhydric acid, precipitating the lead and tin as sulphide and separating them with sulphide of ammonium. The result was as follows:—One-fifth of a square foot gave 1·1650 gram of lead and 0·4469 gram of tin, which would make the tinning consist of 72·27 per cent. of lead and 27·73 per cent. of tin. Terne plate can be readily told by its dulness; it comes also in larger sheets than bright plate.

Although constantly on the watch for tinware made of terne plate, I have been able to find none. I am informed on good authority, however, that it is sometimes used for that purpose, but conclude that such use must be rare in this section of the country.

On Commercial Tin Foil.

Tin foil is so much used now-a-days on chocolate, compressed yeast, cheese, and the like, that I thought the analysis of a few samples might not be amiss. Here at the outset we have a good proof of adulteration, from the fact that the price of most foil is but little more than half the price of pure bar tin.

I collected a number of samples from different importers and manufacturers. They varied greatly in thickness, colouring, and design, but I had reason to suppose that many were the same in composition. I took what I thought was a fair sample of them as regarded composition, and analysed them.

The method used was that usually used for solders, the oxidation with nitric acid. It was not thought necessary to correct for the trace of lead retained by the oxide of tin; neither were traces of copper or other metals sought for, which even if present would hardly influence the character of the foil, at least as far as sanitary purposes were concerned. The results of the analyses will be found in Table V. I give in the table the size of the piece of foil taken from analysis, its weight, and the weight of the lead and tin found in it, as well as the percentage composition. Only the first three foils were sold for pure tin. Some were sold as "composition foils," but generally, unless special inquiry was made, nothing was said of their composition.

* It is hardly to be supposed that the proportion indicated by the above experiments continues indefinitely.

TABLE V.

No.	Amount taken. Size in sq. in.	Weight in grms.	Amount found, in grms. Tin.	Lead.	Percentage. Tin.	Lead.
1	6	0·2285	0·2275	—	99·53	—
2	6	0·4260	0·4227	—	99·23	—
3	6	0·5950	0·5929	—	99·65	—
4	6	0·5150	0·1162	0·3945	22·56	76·60
5	6	0·9080	0·0902	0·8152	9·94	89·95
6	6	0·7140	0·1642	0·5464	23·00	76·41
7	6	2·0785	0·0839	1·9860	3·86	95·75
8	6	1·8580	0·1172	1·7360	6·31	93·43
9	6	0·3030	0·1125	0·1819	37·44	60·03
10	2·25	0·4720	0·1078	0·3678	22·84	77·94
11	3	0·8005	0·2004	0·5969	25·03	74·55
12	6	1·4940	—	1·2240	—	81·92

In order to see if I had had a fair sample of the foils in general use, and to see which of them were most used on articles of food, I took several foils that had been in actual use and analysed them. The results appear in Table VI. It will be seen that each corresponds very nearly to some one in Table V. Nos. 21, 23, and 28,

TABLE VI.

No.	Amount taken. Size in sq. in.	Weight in grms.	Amount found, in grms. Tin.	Lead.	Percentage. Tin.	Lead.
21	6	0·2650	0·2653	—	100·10	—
22	6	0·5145	0·5130	—	99·70	—
23	6	0·2560	0·2559	—	99·96	—
24	6	1·1175	0·1111	1·0040	9·94	89·87
25	—	1·1600	0·2570	0·8733	22·15	75·27

28	2	0·4850	0·0938	0·3879	19·34	79·99

were on chocolate; Nos. 22 and 27 on different kinds of compressed yeast; Nos. 25 and 26 on "Neuchâtel" cheese; No. 24 on the outside of a box of troches. No. 23 was on a small cake of chocolate bought at a street stand, while No. 28 was an embossed foil and on a very fashionable cake of chocolate. No. 25 was very brittle and showed signs of being acted upon. The cheese was quite acid to litmus.*

Mass. Inst. of Technology, Boston, Mass.

DIALYSIS CONDUCTED WITH EMPLOYMENT OF CHLOROFORM WATER, AND ON DIALYSED ALBUMEN.†

The process of dialysis has, during late years, been frequently employed in the study of albuminoids. The results were, however, often unsatisfactory, on account of the insufficiency of the conditions under which it was conducted. The failures may be attributed to the following three causes:—1. The liability of the substances to decompose; 2. the employment of parchment paper; and 3. the difficulty of examining the dialysed substances.

The first difficulty was attempted to be overcome by executing the dialysis at the lowest possible temperature, in the shortest possible time, and by frequent change of the external liquid and the parchment paper. But each experimenter was thereby made directly dependent upon temperature and time, and therefore was never in absolute control of the experiment. In regard to parchment paper, every one who has carried on the process of dialysis knows how difficult it is always to obtain a good and uniform article. London furnished the best paper for this purpose, which was much superior to the German. But even the English paper could not always be relied on, particularly if large surfaces were needed. If we also take into consideration the feeble resistance of the paper and the necessity of frequently renewing it and of working only with small quantities of liquids with avoidance of pressure, it is surprising that this medium has been so persistently retained.

The investigations of the author being such as to necessitate the avoidance of any decomposition in the substances operated on, and to guard against loss by softening or tearing of the paper, he discarded parchment paper altogether, and selected animal bladder or gut. These were first soaked in water, then deprived as much as possible of fatty particles, and finally treated with several successive portions of ether. The prepared bladders or gut were then preserved under ether, in which they keep perfectly for years. In this manner, any desired stock of purified membranes may always be at the disposition of the operator, and one and the same bladder may even be used for several experiments.

As dialysing menstruum (external to the membrane), the author uses chloroform water, obtained by shaking water with chloroform in excess, and subsequently allowing to settle; also pure ether.

[While the author has in view merely the operation of dialysis performed upon solutions containing albuminoids, and with special reference to the subsequent analysis of the dialysed substances, yet the *practical applicability* of the *improvements* described by the author *to many technical operations of dialysis* will at once suggest itself to the reader.—ED. N. R.].

The applicability and advantages of chloroform water as dialysing menstruum is based upon the remarkable antiseptic properties of chloroform even in minute quan-

* The use of a foil containing about 75 per cent. of lead for wrapping the so-called Neuchâtel and other soft cheeses is certainly reprehensible. Owing to the acid in, or developed in, the cheese the foil becomes crumbly, and even when the cheese is first covered with greased paper, particles of the oxidized foil are very likely to become attached to the cheese as it is used. Attention has been repeatedly called to this matter abroad, among others by Wittstein (*Dingler's Polyt. Journ.*, 208, p. 341), who found appreciable amounts of lead in cheese thus wrapped.

† "Die chemische Dialyse unter Anwendung von Chloroformwasser oder Aether, und ihre Bedeutung für die chemische Analyse eiweisshaltiger Substanzen aus dem Thier- und Planzenreich. Von Heinrich Struve."—*Journal f. prakt. Chem.*, 1883, 231. Reprinted from *New Remedies*, July.

tities. This property of chloroform is well known, but it does not seem to have been sufficiently known that the same property attaches to chloroform water.

In the year 1849, Dr. Augend drew attention to the antiseptic properties of chloroform, particularly when compared with ether (*Journ. de Chim. Méd.*). He cited the following experiments:—Three vials with well ground stoppers were selected; a few drops of ether were poured into the first, a few drops of chloroform into the second, and the third vial was left uncharged. A piece of meat was then placed in each vial, and the latter closed. After a few moments already, the following appearances were noticed:—The meat in the vial charged with chloroform had assumed a yellowish-red colour; no change was observed in the vial containing the ether. After one week, the meat in the uncharged vial exhibited no change; in the vial with ether, the meat had assumed a dark tint, and in that with chloroform the meat appeared as if it had been boiled. On opening the vials, it was found that the meat in the first two vials was putrid, and had a fetid odour; that in the chloroform atmosphere was found unaltered, except that it had an odour of chloroform and a disagreeable taste.

These results induced Th. Schmidt, the chemist of the Kaukasian Mineral Water Administration in Piütiporsk, in 1866, to make a new series of experiments with the modification that chloroform water was substituted for chloroform. The results were perfectly satisfactory, a number of animal and vegetable specimens having been preserved for months without alteration in this manner. The author reported on the subject in 1867 at the meeting of the Russian Balneological Society in Piütiporsk, and recommended the use of chloroform water as an excellent vehicle for preserving histological specimens.

The author of the present paper has followed Schmidt's suggestion, and has used chloroform water with uniform success. Its utility and peculiar effects become evident from the examples cited by the author.

In autumn, 1871, some ripe and quite fresh grapes (with the stems and a few leaves) were suspended in glass jars filled with chloroform water and closed with ground-glass stoppers. After a few moments, the action of the water upon the grapes became noticeable. Currents were noticed to proceed from the surface of the grapes, gradually descending towards the bottom, and rendering the water faintly yellow. After a few days the chloroform water in one of the jars was renewed; in the others, a few drops of chloroform were added, and the water stirred up. The action of the menstruum upon the grapes (and leaves) proceeded regularly; the tint of the light-coloured grapes and of the green leaves gradually became brownish, then brown, while the tint of the blue grapes remained unaltered. In some of the jars, the menstruum was regularly renewed every eight days; 200 c.c. of the old menstruum were evaporated and tested for sugar in order to obtain data for the estimation of the rate at which the process advanced. It was thus ascertained that all the sugar was extracted after the menstruum had been renewed about twelve times. From this period the menstruum was but rarely renewed, and in some cases has been left unchanged for four years without any signs of decomposition showing themselves.

The author further describes a series of experiments made for the purpose of studying the successive stages of development of the silk-worm. The several specimens were arrested in their growth by being immersed in chloroform water, and after the water had been once renewed, preserved in the liquid without change.

If the substance to be subject to dialysis is not already inclosed in a natural membrane, or otherwise forms a natural unit, it must be inclosed in a membrane (animal bladder or gut), which is to be tied with white silk and suspended in a glass vessel partly filled with chloroform water. Dialysis will then immediately begin, and the process may be followed in all its details without the risk of decomposition. It is only necessary that the vessel be *well closed*, and that the dialysing menstruum (the chloroform water) always retain the odour of chloroform.

If larger quantities of a substance are to be subjected to dialysis at one operation, it is to be feared that not enough chloroform water can penetrate through the membrane in time to prevent decomposition of the whole mass. In such cases it is well to add a definite volume of chloroform water to the substance itself before placing it in the dialyser.

With the above-described process it will be found that all water-soluble substances will diffuse more or less rapidly, while all substances insoluble in water will remain behind unaltered in chemical nature or form.

The author very properly remarks that in many or perhaps most cases the dialytic process is much more complicated than it would appear at first sight. The principal process, that which alone is open to our observation, takes place at the point of contact of the dialysing menstruum and the membrane. Inside of the latter, however, within the substance to be dialysed, other dialytic processes occur between the contents of any single cells and the surrounding liquid. In consequence thereof, the cells not only lose their water-soluble contents, but also absorb more or less of the dialysing menstruum which produces contractions, coagulations, and other physical changes of the remaining contents of the cells, many of which may be followed and studied with the aid of the microscope.

[The practical application of the author's process is well illustrated by his experiments on egg-albumen, which may be the means of placing at the disposal of photographers and others requiring very *pure albumen* the desired article.]

DIALYSED EGG-ALBUMEN.

It is well known that egg-albumen consists of large, tender, cell-like envelopes, containing a pale-yellowish albuminoid liquid of an alkaline reaction. In order to separate this liquid, the envelopes must be cut (with shears), the separated liquid diluted with water, strained and pressed through linen, and afterwards filtered. But the filtration of such a liquid is a very tedious operation, and never yields a pure product, which is also acknowledged by Hoppe-Seyler, who states that the cellular membrane of egg-albumen has not yet been properly isolated.

If perfectly fresh egg-albumen—such as is obtained immediately after the breaking of the egg-shell and separation from the yolk—be subjected to dialysis in a bladder, with chloroform-water as menstruum, the *albumen will be found to dialyse with remarkable rapidity* until the last traces have passed through the membrane. It is only necessary to renew the chloroform water from time to time, and to test for the end of the process by taking a small volume of the dialysate and evaporating. If this leaves only a trace of a residue, the aqueous solution of which scarcely reacts with tannin, and which leaves only faint traces of ash, the process may be regarded as terminated.

The different diffusates or dialysates are perfectly clear, and have an alkaline reaction. When heated, and even when boiled, *no coagulation* takes place; but traces of hydrosulphuric acid are given off which may be detected by acetate of lead, and may be more amply developed by acetic acid. If the clear solution, however, be treated with acetic acid *before being boiled*, albumen will separate, but without the escape of hydrosulphuric acid, even on boiling.

All these diffusates may be evaporated on the water-bath without any coagulation or opalescence; and if the concentrated liquid be finally completely dried in a rarefied atmosphere over sulphuric acid and chloride of calcium, the albumen is obtained in form of a glassy, faintly-yellowish mass, which is completely soluble in water.

The author has also experimented with *ether* as dialysing menstruum. In this case he observed that the solution and extraction of substances soluble in ether contained in the interior of the object suspended in the liquid (as grapes, cherries, small animals, etc.) was accompanied by an expulsion of all water, together with the substances soluble in the latter. [In fact, the author arrived at the same conclusions which were already in 1876 made the basis of a process for extracting the soluble substances from fresh drugs. The process was devised by Legrip under the name of "dietheralysis," and is described in *New Remedies*, 1876, 168 (from *Répert. de Pharm.*). Mr. Schmidt appears to have remained in ignorance of the existence of this article. As the latter portion of Mr. Schmidt's paper is less likely to be of practical interest to our readers, though very much so to physiological chemists, we content ourselves with referring for further details to the original.—Ed. N. R.]

FREE FATTY ACIDS IN VEGETABLE OILS.

According to E. Schmidt and H. Römer (*Archiv der Pharmacie*) free fatty acids occasionally occur in larger or smaller quantities as constituents of normal vegetable oils.

The oil contained in the seeds and seed-vessels of *Cocculus indicus* consists chiefly of free stearic acid and small quantities of other fatty acids rich in carbon. The menisperm of commerce is in fact nearly pure stearic acid. "Nutmeg butter" contains from 3 to 4 per cent. of free myristic acid, and a small quantity of another acid, perhaps identical with stearic. The oil obtained by extracting dried laurel berries with hot alcohol, distilling off the alcohol, and washing the residue with hot water, exhibits a perceptible amount of free fatty acids, which cannot be separated from one another, but probably consist partly of palmitic acid.

PREPARATION OF LACTIC ACID.*

BY H. KILIANI.

The author recommends the following process: 500 grms. of cane sugar are heated to 50° for three hours, with 250 c.c. of water and 10 c.c. of sulphuric acid, in a flask holding about 2 litres. To the colourless or at most faintly-yellow solution of invert sugar is added, after cooling, 400 c.c. of a caustic soda solution (containing 1 part NaOH in 1 part OH_2), in quantities of 50 c.c. at a time. This ley at first forms a slimy layer at the bottom, and a fresh portion is not added until a homogeneous mixture has been promoted by agitation. The flask is judiciously cooled by cold water during the addition of the soda ley. The mixture easily becomes coloured, and if the alkali be rashly added the development of heat is so great as almost to cause the fluid to boil. In this way the amount of the yield, indeed, is not particularly affected, but highly-coloured products are formed, and the zinc salt subsequently obtained is by no means pure. Lastly, the mixture is heated to 60° or 70°, until a sample, heated to boiling with Fehling's solution, causes no separation of cuprous oxide, and only a green tint. The calculated quantity of sulphuric acid (obtained by mixing 3 parts of sulphuric acid with 4 parts of water and standardizing by titration with the soda solution used) is allowed to flow into the cooled mixture. As soon as the acid fluid is at the ordinary temperature, a crystal of Glauber's salt is dropped in, and the flask is immersed in cold water until a thin crystalline crust has formed on the sides. This is loosened by violent shaking. The cooling and shaking are continued until further formation of crystals ceases. The mixture is now allowed to stand aside from twelve to twenty-four hours until the contents of the flask appear as a cake of crystals saturated with a reddish fluid. Alcohol of 90 per cent. strength is now added, the mixture being shaken meanwhile, until no further precipitation takes place. The separated Glauber's salt is thrown on to a suction filter, and completely washed with a little more alcohol. One half of the filtrate is neutralized with zinc carbonate, on the water-bath, filtered while boiling hot and mixed with the other half. On cooling, crystallization commences at once, as a rule, and is finished when the solution has stood for about thirty-six hours. The lactate of zinc so obtained can be easily freed from the mother liquor by decantation, and especially by hard pressure, so that it is pure after once recrystallizing. The weight of the crystals obtained amounts to 30 or 40 per cent. of the sugar used, and the concentrated mother liquor yields a further quantity of zinc salt. Should a small portion of the mother liquor of the second crystallization, on shaking with ether, yield to the latter free lactic acid, half of the solution is again boiled with excess of zinc carbonate, in order to obtain more crystals, on the addition of the other half of the filtrate.

MICROSCOPICAL SEPARATION OF WHEAT AND RYE-MEAL.

In the Reports of the Botanical Society of Brandenburg, L. Wittmack makes the following statement with regard to the microscopical distinctions between wheat-meal and rye-meal. The amount of starch gives no certain character, nor is the size of the starch-grain in itself sufficient; the maximum size of those of rye is 42 to 52 μ (micromillimetres), of those of wheat 28 to 35 μ. Better characters are the following:—

	Wheat.	Rye.
Average thickness of skin in μ	43 to 50	31 to 40
Length of epidermal cells of skin	116 to 150	136 to 400
Breadth of epidermal cells of skin	20 to 28	26 to 62
Porous pitting	Very close	Less close
Length of subepidermal transverse cells	114 to 192	72 to 90
Breadth of subepidermal transverse cells	14 to 17	11 to 14
Thickness of walls of transverse cells	5·8 to 8·7	3·3 to 5·0
Pitting	Very dense and conspicuous	Less dense, inconspicuous
Average larger diameter of starch cells	56 to 72	40 to 64
Average shorter diameter of starch cells	32 to 40	24 to 40
Diameter of isodiametrical starch cells	40 to 48	32 to 36

The denseness of the pitting in the transverse cells of wheat gives them a chaplet-like appearance. The shell or pericarp is often difficult to meet with in the finer kinds of meal.

Good characters are also obtained from the hairs. Before grinding both ends are removed from the grain; the embryo end on account of the oil which it contains, the opposite apex on account of its hairs; but a few hairs are still to be found in the meal, which yield the following characteristics:—

	Wheat.	Rye.
Length of hairs in μ	120 to 742	50 to 420
Diameter of the largest hairs	15 to 21	9 to 17
Diameter at the bulbous base	28	23
Diameter of the smallest hairs	9 to 10	8
Diameter at the bulbous base	14	11 to 14
Thickness of the wall of the hair	7	3 to 4
Breadth of the cell cavity	1·4 to 2 (rarely 5)	7

Wheat has therefore thick-walled hairs with narrow cell cavity; rye thin-walled hairs with wide cell cavity.

THE INTERNATIONAL PHARMACEUTICAL EXHIBITION IN VIENNA.

ONE of the many beneficial results flowing from the wonderful increase in the facilities for travelling which has marked the last half-century is that it has developed to a large extent the desire for an interchange of ideas between the different countries of the civilized world, and especially of those which from their bearing upon the welfare of every community may be looked upon as cosmopolitan. Science, in the broad sense of the word, has been peculiarly active in this respect, and the advance in knowledge resulting from the establishment of points of contact between many minds, as, for instance, in the numerous exhibitions that have followed more or less closely the great one held in Hyde Park, in 1851, has not been found inconsistent with that other kind of remuneration, which, although not usually considered to be of so high a standard, must always constitute an important factor in any social movement. Amongst other branches of knowledge that have profited by the establishment of such international relations is Pharmacy, and it has been a source of pleasure to us to have been enabled from time to time to contribute to some extent towards bringing about this end. Until quite recently that personal acquaintance which so vastly increases the interest of men in the sayings and doings of each other was almost exceptional as between the pharmacists of Great Britain and of other countries. But the last decade has seen an improvement in this respect, which not only made the International Pharmaceutical Congress held in London two years ago a possibility, but also ensured its success, and we venture to say that the influence of that meeting has already produced a beneficial effect on the interests of pharmacy in this country, and we believe it will continue to do so for a long time to come.

While numerous other branches of technical art and industry have received the advantages that are to be derived from international exhibitions, pharmaceutical exhibitions have hitherto been of a more local character. If, however, we consider the rapid progress that is being made in the sciences and industries connected with the arts of medicine and pharmacy, as well as the keener trade competition between different countries which has resulted from increased facilities of communication, it will be evident that there is ample scope for such opportunities of comparing the condition of the industries connected with those arts in various countries. By such means it is possible to appreciate more thoroughly the necessity for turning to practical account the increased knowledge which science places at the disposal of manufacturers if they desire to avoid being driven out of the market by competitors of other nationalities more alive to the advancement of their interests.

It will be our pleasing duty now to place before our readers some account of an International Pharmaceutical Exhibition lately opened in Vienna, the first of its kind, and we hope of a series of successors in other countries. The proposition to carry out an international exhibition in connection with pharmacy originated with Dr. A. HELLMANN, a pharmacist in Vienna. A motion had been brought forward at the General Meeting of the Austrian Pharmaceutical Society in 1881, by Herr NEDWED, of Gratz, and Herr HELL, the President, to hold an exhibition of the pharmaceutical products of Austria, when Dr. HELLMANN suggested, as an amendment, that the exhibition should be international. This proposal was eventually adopted and in pursuance of it an Executive Committee was appointed to enter into communication with the pharmaceutical societies of other countries; but, with few exceptions, it received little definite support at the outset. By the 1st of May last one hundred and eighty applications had been made for an aggregate space of one hundred and fifty-eight square metres, and upon this basis, which was subsequently much extended, it was decided to carry out the Exhibition. For the purpose of ensuring the scientific character of the Exhibition, and keeping in view its proper object, applications were addressed to a large number of scientific institutes, museums, libraries, etc., soliciting support in the contribution of objects for exhibition. In this direction the Committee has been successful in obtaining many interesting objects from the Austrian Imperial and Royal University, the Court Library, the Library of the College of Physicians, the Medical Faculty in Vienna, the Oriental Museum, the German National Museum in Nuremberg, the Medical Department of the Austrian Ministry of War, and various corporate bodies. It was decided, in accordance with the principles laid down at the outset, to exclude all secret preparations, and to limit the admission of specialties to a few which were of reasonable and scientific character. Having made such progress as warranted the expectation that the success of the undertaking was assured, the Executive Committee addressed to the Archduke CARL LUDWIG a request that he would become the patron of the Exhibition, which he readily assented to. Upon the application of the Committee, Delegates to the Exhibition Commission were also nominated by the Imperial Ministry of Education, the Vienna Chamber of Commerce, the Lower Austrian Industrial Association, and the Vienna Town Council. In order to facilitate the transport of articles for exhibition the Imperial Finance Ministry granted exemption from import duty on goods sent by foreign exhibitors, under the condition that they should be sent back again upon the close of the Exhibition, and the Austrian railway authorities undertook the return carriage of these goods free of charge. Lastly, a Sub-Committee, consisting of Professor Dr. Godeffroy, Dr. Heger, Dr. Hellmann, and Herr Klinger, was entrusted with the preparation of a Catalogue.

The Exhibition is held in the handsome "Floral Hall" of the Horticultural Society, situated in the Park Ring, and a first glance at it shows that it is a decided success as an exhibition, though it must be admitted that on further examination its international character is less marked than would be desirable. This, however, is but a first attempt in that direction, and serves at least to show the utility of such opportunities for comparing from time to time the progress made by different countries and to enable those interested in such an effort to judge as to the best way of carrying it out at some future time in a more extended form. The Executive Committee has also set an exceedingly good example, in spite of numerous difficulties and unforeseen hindrances, in securing the opening of the Exhibition in a thoroughly complete condition punctually upon the day originally fixed. The Catalogue, too, in its completeness and the promptness of its appearance, proves to be a decided exception to the general custom, which postpones the appearance of such books until after they cease to be capable of rendering useful service.

The opening of the Exhibition took place on Saturday, the 11th instant, and long before ten o'clock, the hour fixed for the ceremony, a large number of visitors had assembled in the Hall. The representative of the Archduke Carl Ludwig, Herr von Eybesfeld, the Minister of Education, was received by the President of the Exhibition Commission, Herr von Waldheim, who in suitable words explained the objects of the Exhibition and the considerations which had led to its being undertaken, as desirable not only in the interest of pharmacy but also of the general public. He said that, consistently with the objects of exhibitions held from time to time during the last ten years, it was intended to demonstrate not only to practical pharmacists, but also to the members of the medical profession with which pharmacy was so closely connected for the benefit and service of suffering humanity, the scientific efforts, the discoveries and improvements that have been made in the art of pharmacy, as well as the progress achieved in those branches of trade with which pharmacy has the most intimate relations. In highly complimentary terms he expressed the sense of the obligations the Vienna pharmacists were under to the various public bodies and private individuals who had rendered their assistance in the organization of the Exhibition which they had the honour of carrying out, and more especially to his Imperial Highness for having honoured them by becoming the patron of their efforts. In reply, Herr von Eybesfeld said that, looking upon medicine and its gifted sister and assistant, pharmacy, and those scientific arts which were of greatest service for the public health, he was glad to have such an opportunity of studying the achievements of pharmacy, and of taking a retrospective view of its past history, which presented so many points of interest. Centuries ago it was chiefly in the monasteries that this art was cultivated, and in still more remote periods the physician of the time considered it his business to read the stars and to envelope all his proceedings with mystery. Astrology and alchemy were the associates of pharmacy until the light of science dispelled the clouds of superstition and raised the rude magic of the middle ages to that height of scientific development that the art of preparing medicines had now attained, and of which that Exhibition promised to furnish evidence. As the Latin words upon pharmacists' vessels are understood everywhere and are an indication that pharmacy is an art common to all countries and nationalities in the service of humanity, so the Commission had risen above all differences of nationality and language in uniting to carry out a work of general utility by making that Exhibition international. From this point of view the promoters of the Exhibition might be assured of the sympathy and countenance of His Imperial Highness the Archduke, and in his name he declared the Exhibition opened. The Vice-Burgomaster, Dr. Prix, then expressed his sense of gratitude to the Committee for having organized the first International Exhibition in the city of Vienna, and his hearty wishes that the undertaking would be a success. The several members of the Commission were then presented to the Minister of Education, after which the official inspection of the Exhibition was proceeded with.

The Second reading of the Medical Acts Amendment Bill was on the paper for Thursday, but it had not been reached at the time of our going to press. Mr. Sclater Booth has given notice of the following addition to clause 63:—"For the purpose of compiling the said Pharmacopœia there shall be established a Pharmacopœia Committee consisting of six medical practitioners, to be nominated by the Medical Council, and five pharmaceutical chemists, four to be nominated by the Council of the Pharmaceutical Society of Great Britain (one of the four to be resident in Scotland) and one by the Council of the Pharmaceutical Society of Ireland." In view of the probability of the Bill being read a second time within the next few days, the Secretary has issued instructions to local secretaries and others to have the petitions respecting this Amendment presented to Parliament immediately.

Detection and Estimation of Phenol.*

BY C. THOMPSON.

I. *The Detection of Phenol.*

There is not much difficulty in detecting the presence of phenol, or carbolic acid, as it is more generally termed. The principal methods in use for testing for phenol, are as follows:—

1. *The Solubility Test.*—This consists in seeing whether any of the sample is soluble, either in water or in an alkaline solution.

2. *Lex's Ammonia Test.*†—The liquid is mixed with a quarter volume of ammonia, a few drops of bleaching solution (1 to 20 water) added, then warmed, not heated to boiling; if phenol be present a blue coloration occurs; if the solution is very dilute, the colour will be green, becoming red on addition of sulphuric or hydrochloric acid.

This is said to detect 1 part in 3000.

3. *The Ferric Chloride Test.*—Put solution in a Nessler glass, add 2 or 3 drops of Fe_2Cl_6. A blue coloration is produced if phenol be present. The colour alters very rapidly. One part in 2000 can be detected by this method.

4. *Plugge's Reaction.*‡—This depends on the action of $HgNO_3$ on a solution containing phenol. When such a solution is added to a solution of $HgNO_3$, it slowly reduces the mercury, evolves a smell of salicylol, and at the same time the solution acquires a deep red colour. The author of this process declares it to be a most delicate one, being able to detect 1 part phenol in 60,000 or even in 200,000 parts of water.

5. *Pollaci's Test.*§—When a solution of phenol is oxidized by means of sulphuric acid and bichromate of potash, a brown coloration is produced, and if the solution be strong, a precipitate will be formed.

6. *Landolt's Bromine Reaction.*—This test, which is described later on, in connection with the estimation of phenol is the best and most certain means of detecting the presence of phenol.

II. *Estimation of Carbolic Acid.*

Until a comparatively recent date, phenol was estimated either by the "solubility" test or by the "ferric chloride," but since the introduction by Landolt, of bromine as a test for phenol, the two former have somewhat fallen into disuse, owing to the greater accuracy which can be obtained by the use of bromine.

First, as regards the "solubility" method. This may be worked either with water or an alkaline solution.

The sample to be examined is shaken up with sufficient water or alkaline solution to dissolve it, were it all phenol, and the amount of oil undissolved is measured.

With pure water there exists a difficulty, as the insoluble portion will partly rise to the top, partly sink to the bottom, and part again stick to the sides of the tube. This may be overcome by adding olive oil to the sample, which dissolves the impurities. Should not be added until after shaking up with water.

Making the test with a solution of fixed alkali presents fewer difficulties, but as some of the impurities not phenol dissolve in the alkali, the results are generally too high.

In either case the results are usually too high, as the crude phenol may hold a considerable quantity of water, which by this method is counted as phenol.

The ferric chloride test is a colorimetic one. To apply it, make a solution, say of 10 grams to the litre, filter it to clear it, and then comparing the colour obtained in 10 c.c. of this solution by the addition of two or three drops of ferric chloride, with the colour obtained in a solution of phenol of known strength in the same amount of reagent. The difficulty is that solutions of crude samples often afford a very different colour from that obtained with pure phenol; moreover the colour alters very rapidly as to give great difficulty in making a satisfactory estimation.

This method cannot be used with carbolates of lime or similar preparations.

In 1871, Landolt (*Deut. chem. Gcs. Ber.*, iv., 750–773), whilst testing for phenol in a well water, found that bromine water was a far more delicate test than any then known (1 in 43,700; Pollaci, 1 in 15,000). The addition of bromine water to a solution of phenol gives an immediate white precipitate of tribromphenol, according to the equation:—

$$C_6H_5-HO+Br_3=C_6H_2\begin{cases}Br_3\\HO.\end{cases}$$

Landolt used this for the estimation of phenol by filtering and drying and weighing the precipitate. This is open to one great objection, as pointed out by Koppeschaar, that since the tribromphenol melts at 91°, some of it is lost in drying at 100° C., so that it has to be dried over H_2SO_4, or else *in vacuo*, thus taking some time. Excess of Br must be added or else the precipitate redissolves in the solution of phenol.

Weight of phenol present $=\frac{28\cdot4}{100}$ of the weight of $C_6H_2Br_3HO$.

In 1876, Dr. Koppeschaar (*Zeitsch. Anal. Chem.*, 233—245) proposed a volumetric method for the estimation of phenol, based upon Landolt's reaction, which he says is uncertain. He gives two methods; in the first, he uses a standard solution of Br water, the strength of which is ascertained by the use of a solution of $Na_2S_2O_3$ of such strength that 1 c.c. = 1 c.c. of a solution of KI (5 grams to the litre). Br water should be such that 50 c.c. after the addition of 5 c.c. of the KI solution require from 18 to 20 c.c. $Na_2S_2O_3$.

Suppose a = number of c.c. used for this; 4 grams of the crude phenol are weighed up, dissolved in 1 litre of water; 25 c.c. of this are taken, put in a $\frac{1}{2}$ litre flask, filled with Br water up to the mark, well shaken, allowed to stand quarter of an hour, rinsed into a beaker containing 10 c.c. KI solution. Iodine set free, determined by $Na_2S_2O_3$ and starch solution.

Let b = number of c.c. used, then percentage of phenol $=0\cdot61753\ (9\cdot5\ a-b)$; process only fairly accurate, variation of 2 per cent. in results.

Bromine solution must be restandardized every day at least.

In second process he uses a solution of a mixture, 5 parts bromide, 1 part bromate of potassium or sodium, preferably latter. The strength of his solution was such that 50 c.c. mixed with 10 c.c. KI solution after decomposition with HCl (5 c.c. diluted with 100 c.c. H_2O) required from 86 to 95 c.c. $Na_2S_2O_3$ solution.

Let a = number of c.c.

To conduct this process 25 c.c. of solution of phenol to be examined, and 100 c.c. of the solution of the mixture of NaBr and $NaBrO_3$ are run into a 250 c.c. bottle, 5 c.c. HCl added, well shaken, stand quarter of an hour, rinsed into a beaker after addition of 10 c.c. KI solution, and treated with $Na_2S_2O_3$ and starch solution.

Let b = number of c.c. required. Then percentage of phenol $=0\cdot61753\ (2\ a-b)$.

Four results:—

99·2.
99·5.
99·3.
99·5.

Advantages over use of Br water, always having a standard solution at hand.

Since Koppeschaar's process several modifications have been published, only a few of which have any merit, *e.g.*, Dr. Waller's, Giacosa's, and Seubert's.

First, as regards Dr. Waller's* process. The originality here is in the addition of a solution of alum in dilute sulphuric acid to the solution.

The following is his process:—

Three solutions required.

1. A solution of pure phenol, 1 per cent.
2. A solution of Br, 30 c.c. = 10 c.c. phenol solution.
3. Solution of alum in dilute H_2SO_4 crystals of alum shaken up with dilute sulphuric acid (100 c.c. to 1 litre water).

Process.—Ten grams is dissolved in 1 litre of water, filtered through dry filter, and 10 c.c. taken; run into a 6 to 8 ounce stoppered bottle, 30 c.c. alum solution added, and in a similar bottle are placed 10 c.c. standard phenol solution with 30 c.c. alum solution.

Br water is now run in from a burette, the bottle being shaken after addition of a very few c.c. Towards the end precipitation is rather slow, but when the phenol is quite saturated a *very* slight excess of Br gives a decided yellow tint to solution. If precipitation does not readily separate the addition of some of the precipitate from standard phenol will cause it to quickly separate.

As the effect of Br on the homologues of phenol, such as creasol, phenol, etc., is most likely the same as on phenol; these, if present, will be reckoned as phenol.

Aniline, toluidine, if present, should be removed by treatment with alkali, etc.; these will not be found in ordinary commercial carbolic acid, but usually are in dead oils.

Giacosa's† process is very similar to Waller's, except that he does not use alum solution, and determines the point of saturation by means of a solution of KI in starch. He uses a 1 per cent. solution of phenol and a Br solution of same strength as Waller.

Instead of adding the Br water to the phenol solution the order is reversed, the Br solution being placed in a beaker and the phenol poured in, stirring quickly all the time. As long as any excess of Br is present, the supernatant liquid will be yellow and turbid, but on adding the phenol solution drop by drop the point of saturation will be indicated by the solution becoming clear and colourless.

Neither of these processes can be quite accurate, owing to the liability of loss of bromine, more especially in the Giacosa's method. Also there is the trouble of retitrating the Br solution every day.

Waller says that the variation is not more than 0·1 to 0·2 c.c. on 10 c.c. of standard phenol solution.

A method giving rather less trouble, inasmuch as it saves the bother of restandardizing, is to use a solution of the mixture recommended by Koppeschaar. This was proposed by Seubert (*Chem. Soc. Journ.*, 1882, p. 106). He uses a solution of KBr and $KBrO_3$, and phenol run in until a drop after filtration no longer gives any coloration to KI and starch paper. Necessary to filter because $C_6H_2Br_3HO$ has the power of liberating iodine.

After working on these processes it struck me that as good a way as any was to make a standard solution of NaBr and $NaBrO_3$ (using a 1 per cent. solution of pure phenol to standardize it with) of such a strength that 100 c.c. on addition of 5 c.c. HCl saturate 10 c.c. of a 1 per cent. solution of pure phenol. The plan I have adopted is to weigh up 1 gram of substance, and dissolve in 100 c.c. H_2O; then place in an 8-oz. stoppered bottle, 100 c.c. of the standard solution of NaBr and $NaBrO_3$, and 10 c.c. of the sample treated as above, add 5 c.c. HCl, stopper, and shake it vigorously; allow it to stand quarter of an hour, then titrate back with a solution of pure phenol, 1 c.c. of which = 1 milligram.

SOCIETY OF ARTS.

Solid and Liquid Illuminating Agents.*

BY LEOPOLD FIELD, F.C.S.

Lecture II.

Adhering to the plan of commencing *ab ovo*, we will apply ourselves in this lecture to the study of those substances which can be used for illumination in a crude manufactured form, or, rather, with unchanged chemical composition. Tallow, beeswax, and sperm wax are the chief of such naturals, and we will discuss them accordingly.

I have already referred to the distinction drawn by Apuleius between *cerei* and *sebacei;* also to the fact of wax candles having entered into certain rites of heathen worship. Partly from the smaller supply, chiefly though, no doubt, from the superiority of its appearance, hardness of grain, and sweeter odour, the wax candle has ever lorded it over the unsavoury tallow dip, associated with kitchen and garret, while the wax taper suggests cathedral and boudoir. In days before gas and Argand lamps, people's rank was not unfrequently gauged by the class of candle they affected. "Wax candles in the school-room!" says Mrs. Elton, in 'Emma.' Lord Bacon, in his 'Natural History,' extols wax lights as lasting longer than tallow candles, because "wax is more firm and hard." Tallow, however, can never be regarded as a good illuminant. Look at this clumsy apparatus of tray and snuffers, with the candle guttering in long winding sheets, every drop on the brass candlestick being marked by a green spot of "verdigris" (stearate of copper); and the long red point of the unconsumed wick protruding from the dull brown flame, exhaling nauseous odours, both from unburnt and burnt tallow. One would have imagined that such a candle would have fallen a victim to popular execration when Chevreul and Young provided their cheap and beautiful substitutes. But no, tallow candles are still burnt in tons—miners, cobblers, and other traditional craftsman adhere to the light of their fathers—and so we cannot avoid entering into the details of their manufacture. It may be, perhaps, that the recommending qualities of tallow to certain classes are, the readiness with which it adapts its form to circumstances, enabling it to be stuck into any crevice, without bending, as cheap paraffin will, and the large wick, keeping alight in draughty places, and giving a bulky flame, without much smoke.

Referring to old manuals of candle-craft, I find blendings of tallows recommended; certain proportions of beef and mutton fat. The best brand for the purpose is known as P.Y.C., which, I believe, means Petersburg Yellow Candle (tallow implied). This article has lost its prestige of late years by the enormous imports of Australian substitute, and now appears to serve rather as a basis of speculation than in any commercial capacity. However, the tallow should naturally be as hard as possible, without risk of cracking, which result can only be attained by experienced selection. The fat from various portions of the animal is rendered, *i.e.*, boiled well with salt (or acid) water till the fibrous portions have settled out, and the tallow swims white and sweet on the top. Of this, with no more ado, candles are made. A truly ancient form of tallow candle is the rushlight. As it is now, so it must have been thousands of years ago; it being impossible to figure a more primitive stage of existence than you see here. A rush, deftly stripped of its skin, of which a slender streak is left to act as a kind of backbone to the tender pith. A number being thus prepared, are allowed to become thoroughly dry, by hanging in an airy loft. They are then tied by the tops in little bundles of four or six, which are held in the hand, being kept apart by the intervention of the fingers. Thus disposed, they are discreetly immersed in the tallow, of a temperature just high enough to preclude solidification in

* Cantor Lectures: Delivered Monday, February 5th, 1883. Reprinted from the *Journal of the Society of Arts*.

bulk, yet to ensure a sufficient portion adhering to the cold rushes. After two or three dippings, the candle is complete. It remains now to let it harden and whiten, to which end it returns to the aforesaid loft, and in about a month of favourable weather is ready for sale. I had considerable difficulty in obtaining these specimens of rushlights, although my inquiries were made in the most out of the way country places. In Hampshire, I came across this instrument, which is really interesting, and which I am told is still used in the Isle of Wight farms. A small deal strip is stuck upright at angles to a broader piece of wood, which acts as a firm basis. The upright board is furnished at the top with a rude iron clamp, which holds the long rush, dipped once or twice into grease. The rush, as you see, is held at an angle of 30° to the basis, on which the end rests, the ash droping on the table. A more primitive candlestick and light cannot be conceived. But the rushlight itself I found, singularly enough, in the heart of London, where, imprisoned in a tall gauze shade, it still illumines, in perfect safety from fire, many a humble sick chamber. One very good quality of this light is the absence of snuff; the wick consuming as it reaches the air, leaving nothing but a slight feathery ash.

I cannot say when cotton wick was introduced. Oakum (*stuppa*) and papyrus (*scirpa*) were the ancient substitutes; but most probably, with us, the wicks were made of linen, gradually giving way to cotton, as that material became more familiar. All candles were "dipped," "rolled," or "poured," till the Sieur de Brez, in the 15th century, introduced the "mould" candles, which rapidly asserted a position of superiority. Of these we cannot speak till the last lecture, and with regard to dipping, not much remains to be told. The principle remains the same; but the pressure of increased consumption, concurring with superior mechanical skill, brought about several improvements in the method of working. The wicks were hung on hoops, and a row of three hoops on one arm of a revolving wooden star, so contrived that only three hoops at a time should pass over the kettle. Once in position, the craftsman depressed the arm with the three hoops pendant, which were withdrawn, on release, by the antagonistic weight of the opposite spoke. So with all the arms in rotation, and by the time the first came round again, the candles would be ready for another dip. The whole arrangement was suspended to one arm of a scale beam, which indicated when the candles had attained the legitimate thickness.

This was a great saving of labour, but still each individual wick had to be cut and fastened to the hoop. A good method of obviating this is shown in this retangular iron frame. To one corner I fasten the end of a wick on this reel. Adjusting the frame to a simple revolving appliance, I turn the handle rapidly, and you see the wick wound upon the frame. It is then secured tightly by a little clamp at either end, and a number of these frames adjusted to the revolving spokes already described. After one immersion, the wicks are rigid enough for independent action. Accordingly, a sharp knife is drawn along either row, at the base. Now, you see, the rudimentary candles swing loose, the lower part of the frame is removed, and the dipping proceeded with *en règle*.

Another form of tallow candle is the "flat candle," a kind of twin, or two candles joined side-ways, and flattened. This is much affected by cobblers, for no reason that I can see, except as alleged by a sutorial interlocutor of long experience, that it gives twice the light of an ordinary candle—in which, as it has two wicks, there is, perhaps, nothing remarkable.

The great fault of tallow candles, dips or moulds, is their tendency to gutter, and to exhale evil odours when blown out; also, the necessity for snuffing them. The first two vices are ineradicable, lying at the root of the composition of tallow itself. Being a mixture of hard stearin and soft elaidin, the latter melts first, and consequently overruns the hard cup formed by the former, producing the domestic phenomenon of "winding sheets." Again, each of the commixts is a compound of fatty acid, stearic and elaic, with glycerine. This conbination has to be split up, which operation, consuming heat, dims the light to begin with; and the malcombustible glycerine is vapourized as *acrolein*, a highly pungent compound. It remained for Chevreul to purge the candle from this abomination; Mr. Palmer, however, took the wick in hand, and, by a happy invention, rendered snuffing unnecessary. He introduced a fine thread (technically called "the doctor"), impregnated with impalpably powdered bismuth, into the body of the wick, which, further was not twisted after the ordinary fashion, but consisted of a number of parallel threads bound together by another one wound round them. The bismuth fuses into a little ball, the weight of which draws the wick laterally out of the flame into contract with the air, having performed which duty, the bead oxidizes, and volatilizes away. Here you have one of "Palmer's Metallic Wick Candles," burning side by side with an ordinary dip, and the difference in burning renders comment superfluous. Mr. Palmer has very kindly supplied me with a number of wicks and candles of different structure and for various purposes. In this large candle there are three convolute wicks. These were wound spirally round a rod, clamped at the top; the rod introduced into a mould, as here shown—the mould then filled with tallow, and allowed to cool, when the rod was withdrawn, leaving the wick round a tubulated passage up the centre. This kind of candle was much used in the candle lamp, of which I have here a very old specimen. You see the three wicks, untwisting as they burn, each with its bright little head. The flame is large, but owing to the reasons alleged before, not luminous in proportion.

Later on, I hope to give you some numerical values of the luminosity of candle flames, which will show you the great difference in the burning of stearin with, and stearic acid without, glycerine.

We have talked enough of tallow now, and shall discover nothing more to its advantage. By pressure, the softer elain may be, to a great extent, removed; look at this brilliant, blue-white substance, which you would hardly know to be tallow; and, again, at this mould candle made from it, burning without guttering, and with a metallic wick. Still the light is dim and the smell evil. In our fourth lecture you will see, though, how the coarsest tallow can be made, by the chemists' art, to rival paraffin in brilliancy of light, spermaceti in whiteness, and wax in cleanliness, sweetness and hardness.

Wax next demands our consideration. Here I must call your attention for a moment to the manner in which I divided the various substances that subscribe to the definition of fats. This is quite arbitrary on my part, but I am emboldened by the fact that every authority on the subject has followed his own ideas, and given his own definitions. Fats proper, I think, are such bodies as yield glycerine upon saponification. According to this definition, very few of the bodies we shall have to discuss can be called fats. But I have given the word a broader signification, and propose to extend the name to embrace all substances which possess both lubricity and inflammability, and leave a more or less permanent transparent stain upon paper. By taking, for the nonce, this view, we are enabled to include the paraffins, olefins, and waxes; also turpentine and camphor, with their isomeric essential oils. Oils themselves have long been divided into *fixed* and *volatile*, the latter being also termed *essential*. With these we have nothing to do; they are all isomeric either with turpentine, as lemon, bergamot, orange, and many other well-known essences; or with camphor, as rosemary, lavender, rue, and that class of perfumes. Turpentine and camphor may have to be mentioned in the lecture on lamps, but quite *en passant*.

The term *wax* used to be applied solely to beeswax, but of late years the introduction of paraffin, solid and liquid, has led to the name being employed to distinguished the first, paraffin proper, from the oil. So the white solid rejoiced in the designation, "paraffin wax," until the cognomen being dropped altogether, we find certain companies advertising their goods simply as "wax candles," a confusion of names which must be deprecated, as tending to mislead; perhaps, however, this is the end in view.

Wax may be defined as bodies of a certain viscid plasticity when warmed, consisting of fatty acids of the series $C_nH_{2n}O_2$, either free, or in combination with an alcohol radicle; they do not yield glycerine upon saponification, which is effected with difficulty, and the soap formed is sparingly soluble in water. Following these lines, we have the following genuine waxes of interest to us:—

		Origin.
Animal...	Beeswax	*Apis.*
	Spermaceti	*Physeter macrocephalus.*
	Pih-la	*Coccus sinensis*
Vegetable	Carnauba wax.	*Copernicia cerifera*
	Myrtle ,,	*Myrica cerifera*
	Palm ,,	*Ceroxylon andicola*
	Japan ,,	*Rhus succedanea.*

We will take these seriatim. *Beeswax* is the gift of the ordinary bee. It has long been an open question whether the wax was in the pollen of the flower, the bee acting as a mere vehicle, or whether the insect evolved the wax by some process best known to itself. When, on experiment, it was found bees who were fed entirely on sugar continued to produce wax, the question was considered settled; namely, that the wax was as genuine a bee product as the silk of the worm. But later investigations show that, after two or three days' sugar diet, the bees fail to supply any more wax, and ultimately die. Carefully considering all I have been able to find upon this subject, I am inclined to think that pollen is necessary for the formation of wax; in the first place, it nourishes the bee, containing nitrogen, which sugar does not; and, secondly, itself containing wax, probably gives the initiatory to the wax-producing organs. It is a fact, that a colony of bees, deprived of pollen, will take eighteen ounces of honey to produce an ounce of wax; whereas, with a proper supply of "bee bread," only fifteen ounces will be consumed in making the same quantity. The wax exudes from between the lower rings on the abdomen of the bee, and is worked up between the fore paws, for though of high melting point (145° F.), it becomes plastic at 90°, and can be readily moulded. The composition of beeswax has been fruitful subject of discussion among chemists, who have obtained results of startling discrepancy. This is, doubtless, due rather to the adulteration of the wax before analysis than variation in the substance itself; it being generally found that substances of animal origin are very uniform in composition. Mr. Otto Hehner has recently made a most exhaustive investigation of a great number of different waxes, and comes to the conclusion that the average composition is—

Cerolein.........	(?)
Myricin......	88
Cerotic acid	12
in	100 parts of wax.

These two constituents may be easily separated by boiling the wax with alcohol, when the cerotic acid dissolves, leaving the myricin, which is a true typical wax, being a palmitate of myricyl $\left.\begin{matrix}C_{16}H_{31}\\C_{30}H_{61}\end{matrix}\right\} O_2$: it is finely crystalline. Perhaps, if there be *cerolein*, it is that which, by its abundance or exactness, gives the characteristic qualities to all these different waxes. On this stand there are over forty varieties, from every country at all noted for that product, and yet an experienced eye and nose will pick you out and assign most of them to their native lands. Here we have bright yellow wax from Holstein and Denmark, the golden produce of Senegambia, the particoloured mixture from Australian hives, and the soft, dark ceral of Mogador. This gamboge-tinted specimen comes from Mexican woods; this is wasp-wax soft and dirty looking; this again, almost white, comes from Brazil. According to Mr. Hehner, whatever the physical properties and appearance of these multichroic specimens their composition varies but little. Even that little he inclines to attribute to man and the advance of civilization rather than to any fault on the part of the bee. Of old, if the sable bee-owner had not sufficient tale of wax, he artlessly introduced a stone or lump of iron, or a bone or two to make up the weight, or, at most, stirred in a quantity of coarse sand. But now every conceivable fat, cheap paraffin (imported for the purpose), palm oil dregs, etc., are employed as adulterants, not detected till the bleaching ground or candle, by defective performance, exposes the deception. There is no remedy. The agent who collects the tributary supplies from a hundred homesteads mixes all the lots, and the hundred agents' deliveries are again thrown together. What help is there? But, by careful sampling, a keen buyer manages to escape with about 75 per cent. of pure wax. This comes to the factory as you see it, and, in its present form, is useless. The first step is to "clear it down"—which is much the same as "rendering"—boiling with a little weak acid and water which separates all dross, and leaves the wax clean though dark in colour. The next operation is that of bleaching. This may be done in two ways; by air or chemical action. The latter can only be applied to wax that is not intended for candles; the grain becomes highly crystalline, and the burning power deteriorates. Why this is I cannot say as yet; we must look to Mr. Hehner's researches for the future explanation. To whiten the wax chemically it is treated with sulphuric acid and bichromate of potash, whereby ozone is liberated, and that discharges the colour. As the chromium salts impart a powerful green tint to the wax it has to be boiled considerably with further libations of acid water till, finally, it assumes this appearance. Observe how short and friable the grain here—you will see the crystalline structure upon closer inspection. If I were authorized to hazard an explanation it would be, that in the gentle performance of atmospheric bleaching the *cerolein* (presuming such to exist) only is destroyed; by the violent attack and heat of the chromic acid, the myricin is split up into acids, palmitic and cerotic. In brief experiments I have found that air-bleached wax dissolves in alcohol to pretty nearly the same extent as when crude, while the chemically whitened body is far more soluble than before, which, if correct, points to a great increase in the quantity of acid, and decrease in myricin. My assistant is now performing the operation of chemical decolorizing. Observe the deep green colour, and great heat, sufficient, as you see, to boil alcohol. After the lecture I will show you the small cake of wax, not entirely blanched, but much whiter than before.

To bleach beeswax atmospherically requires time and fair weather. The melted wax is allowed to trickle through a slit pipe over a drum revolving in water. This divides it into ribbons, which are rescued from the water by a rake, and spread on long canvas sheets—about forty feet by three feet. Here they sojourn during the fine summer days, being discreetly tossed and turned, and sprinkled judiciously with water till the colour is discharged from the outer film. Again melted and divellated it undergoes another exposure, and yet, perhaps, another, according to its nature, till of the yellowish-white peculiar to itself. It is then run into cakes and stored for use. We may as well follow it to the end, and see how it is made into candles. A very favourite method in olden days was to apply the wax, made plastic in hot water, to the wick with the hand, by kneading and manipulation, reducing it to proper form. But this was a lengthy process, and the water was difficult to expel, producing spluttering. The candles were also dipped like tallow-lights; but this method would only answer in short cases, and the generality of wax lights are passing long. Moulding, somehow, will not answer with wax; the candles refuse to leave the moulds, or crack while doing so. So now they are "poured." Round this wooden hoop you will notice a number of strings, to each of which, by means of a little wax, my assistant will join a wick. The hoop is now hung over a cauldron of melted wax, "and, be very careful, I pray you," says an old manualist, "of the temperature, lest, all too hot, the wax refuse to adhere to the wick; or too chill, hardens before the whole length be run." Dipping a ladleful from the cauldron the operator revolves the hoop with one hand while he pours the fluid material over the wicks with the other. After three or four revolutions, that hoop is laid aside and another taken in hand. On this frame the candle is arranged *in crescendo*, showing the increment gained after each pouring. At a certain period the candles are reversed, as the tendency is naturally to thicken at the lower extremity. Being now of tolerably even diameter, though unsightly, they are plucked from the strings, and laid in a row of about six upon a marble slab sprinkled with water. The maker then proceeds to roll them under a board upon which he throws all his weight, and by this the still plastic substance is rendered of a smooth and even surface. With knife and gauge the candles are cut to the required length, and their tops trimmed with a piece of wood. Hand labour, you see, throughout, and requiring much skill and experience. A well-made wax candle should show rings like a tree, where the different layers have been superfused.

To make the little Christmas tapers and wax spills a method called "drawing" is employed. Here the wick is wound off one drum on to another. In its passage it passes through a basin of melted wax, coloured with pigment, leaving which it passes through a die perforated with holes varying in diameter from $\frac{1}{30}$ to $\frac{1}{2}$ inch. The wick passes and re-passes till sufficiently thick. The large sizes are cut into tapers for Christmas-trees, the thin wicks into lengths of about 8–12 inches, and are made up into bundles of assorted colours. To "feather" the ends, to facilitate lighting, they are dipped into hot water and "flipped" over the arm, the melted wax flying off, and the ends dispersing.

Considering the expense of the raw material, also the skilful labour and time required for its manufacture, it is not surprising that wax candles should be dear, and highly prized. They have long been the currency for paying spiritual debts, and many tons of candles are devoted to this purpose. For carriage lamps, where a hard substance is required to resist the upward pressing spring, wax "moons" were long the only ones adopted, till ozokerit literally "took the shine" out of wax in light and hardness. Many quaint and obsolete customs were connected with the candle, as "selling by candle," when the bid was knocked down after a certain length had burnt; "excommunication by candle"—

"The priest called for candle, for bell, and for book,"

where the grace and time for penitence were adjudged by the same measure.

The introduction of cheaper substitutes has enabled many to reconcile piety and economy. Vegetable waxes are as taintless as beeswax, and, being some of them harder, last longer. Of these the name is legion, and we can only consider the most important; but, first, we must devote some little time to the beautiful rival of beeswax, spermaceti, itself a true wax.

Spermaceti (*Wallrath*, Germ.; *Blanc de balaine*, Fr.) is written in old works *sperma ceti*, testifying to the belief then current that it was the spawn of the whale. The history of the rise of this industry is fraught with interest. Till nearly 1700, men's ideas concerning the nature of the substance were very vague. Sir Thomas Browne excuses his ignorance on the plea that "the learned Hoffmann says, '*nescio quid sit.*'" In 1686, doubts were set at rest by the finding of a dead whale on the coast of Norfolk, from which unmistakeable spermaceti was taken. When this solid came to be employed in candle manufacture, for which it is so eminently adapted, I do not know. It seems for a long time to have been employed in pharmacy alone. Thomas Browne, for instance, lauds it as a "ground for compound oyls and balsams," and another old *savant* prescribes it in all cases "where acrimonious humours are to be obtunded;" and so in many others. It is still very largely blended in unguents, as I need not remind you; but, of course, now its chief use is for candles.

The black or Greenland whale fishery was carried on long before the haunts of the sperm or cachalot whale had been discovered. The earliest mention made of the latter is by one Mr. Norwood (1667), who, talking of the Bermudas black whale fishery, "has heard from credible persons of another whale having great teeth—from which they got, as it lay dead on the beach, a quantity of *sperma ceti*;" and Mr. Stafford, several years after, speaks of the difficulty and danger of catching the sperm whale, "such is its fierceness and swiftness."

But the matter was not allowed to drop there. America took to the chase so kindly that, between 1775 and 1779, she sent out nearly five hundred ships to both north and south Atlantic Oceans, which brought in over 30,000 tons of oil. Mr. Burke remarked witheringly on the sloth of the English in this matter, as compared with the activity of their cousins. "No sea, but is vexed with their fisheries, no climate that is not witness of their toils." This appears to have taken effect, for, in 1776, the Government offered a large bounty to the largest cargo of sperm oil brought home under certain specified conditions. From this time forward the cachalot whale must have been surprised to find himself the recipient of such marked attentions. In the year 1786, above 326 tons of pure sperm oil were introduced into England. The bounty was increased, and almost immediately afterwards the great step was taken of doubling Cape Horn, hitherto an unaccomplished feat, and carrying the war into the Pacific, the real home of the sperm whale. The captures now doubled and quadrupled. In 1819, Mr. Enderby, who had already received two bounties for two ships which had made voyages of most unprecedented good fortune, fitted out the *Syren.* This vessel chose the new hunting grounds of the Japan sea, and with such judgment that, after two years' absence, she returned with the enormous cargo of 346 tons of sperm oil. The trade being now fairly started, the Government discontinued the bounty. But the impetus given received no check—the gain of sale was sufficient inducement; and the cargoes increased in number and tonnage, till 1831, when 7065 tons came into British ports.

It is difficult for even a fertile imagination to overpaint the advantage which accrued to trade, science, and navigation, through the enthusiastic following up of this exciting fishery. We shall find a parallel, perhaps, in the palm oil trade, though of a different scope. When one considers the vast extent of water over which these leviathans roam at will, and the remote fastnesses to which they fly from their pursuer, also the enormous yield got from their carcases without other expenditure than the fire to "try down," and the barrels to hold the oil, it needs no dilating to show how universal benefit must result.

The details of the fishery are known to everyone. Not quite so well, perhaps, the difference between the three whales—the "right," the "sperm," and the "bottlenose." There are, of course, innumerable species of this order of mammalia, ranging from the seal to the porpoise, all of which yield oil; but we can only give the most cursory consideration to the above-named three. The Greenland, or "right" whale (*Balæna grœnlandicus*), also known as the "black whale," yields whale-oil, which, in many ways, differs from sperm oil. This balæna inhabits northern latitudes chiefly, but is found astray in many southern regions. He is toothless; his mouth is furnished with whalebone, and his head is rounded, the skull being of an entirely different form to that of the cachalot. His fat is also more readily saponified, and deposits little solid on cooling; the lighting and lubricating properties also are far inferior. The cachalot, or sperm whale (*Physeter macrocephalus*), so called from its enormous head—nearly 14 feet high by 25 feet long—is a denizen of the south. His skull is long, depressed and pointed. The great bulk of the head consists of a dense cellular tissue infiltrated with spermaceti. This is called the *junk*, and is surmounted by the *case*, which holds nearly a ton of very fine oil and sperm. This is termed the *head matter*, and it is still asserted, in most books on the subject, that this is the only source of spermaceti. The error—for such it is—has arisen from the fact of the head matter being full of the sperm crystals when taken from the head; while the body oil does not deposit till after melting and cooling out. The *blubber* surrounds the whole body in a layer of about 18 inches thick. It is a fine fat, much resembling the fat of hot roast beef, and is hardly solid at ordinary temperatures. This is stripped off the whale, and packed into barrels unless "tried down" on board ship. Trying down means simply melting, to clear down the fibre and skin from the oil. This soon deposits thick scales of sperm, and arrives at the factories in a semi-solid condition; in winter the barrels have to be steamed, to extract the contents. The mass then undergoes several filtrations and pressings. At first it is run into long bags of hair or canvas, and allowed to filter simply by its own weight; any pressure at that stage tending to force the only semi-solid sperm through the fibres. This process is called "bagging." When as much oil has filtered out as possible, the flaky mass is tranferred from the long bags to square ones, which, placed between boards in layers, are subjected to pressure by superposed weights, gradually increasing till a certain limit. Hydraulic pressure is then applied, in the cold at first, afterwards with the aid of heat, the sperm having been melted and cast into moulds once or twice during the different pressings. Finally, the almost white wax is warmed and agitated with a little caustic potash, which removes the last traces of colour, and then is cast into blocks. Thus purified, spermaceti is an almost blue-white glistening semi-crystalline substance, melting at 113° F. Messrs. Bicknell, the well-known sperm finers, who kindly placed their factory at my disposal for the above information, have prepared this block of sperm for exhibiting the crystals. The interior has been run out while warm, leaving the splendidly serrated interior displayed. They are not true crystals—as far as I know, no distinct form has been isolated—but are, nevertheless, highly structural and characteristic. It is my belief that palmitate of cetyl itself would be crystalline, but that the inseparable constituents prevent this.

The constitution of sperm has received a good deal of attention, though, like all the fats, very difficult to ascertain exactly. It mainly consists, as I said, of cetyl palmitate $\left.\begin{matrix}C_{16}H_{31}\cdot\\C_{16}H_{33}O\end{matrix}\right\}O\cdot$ which on distillation, yields a peculiar substance, called *ethal* (cetyl alcohol, $C_{16}H_{33}OH$) the alcohol of cetene $C_{16}H_{32}$. On long boiling with potash, sperm, like other waxes, forms a quasi-soap, but yields no glycerine, cetyl being liberated instead.

Owing to the pure condition to which it can be brought, and the uniformity of its constitution, sperm makes the finest candles we have for regularity of flame. Having large wicks, to allow of quicker consumption of the easily melting wax, the flame of a sperm candle of ordinary size is greater than those of others. For these reasons, the spermaceti candle, burning 120 grains per hour, has been chosen as the standard measure of light over all the scientific world.

The "bottle nose" whale has been a subject of much doubt, and great though surreptitious utility. The *Balæna rostrata* of Fabricius (Hunter, *Phil. Trans.*, 1787) is the true bottle nose whale. It is smaller than the balæna and cachalot, seldom exceeding 30 feet. Although, no doubt, thousands of these fish have been caught, and their oil sold as sperm oil, it is only quite recently, that the oil has been made a distinct commercial article. Messrs. Bicknell have taken the matter in hand, and extracted, after much experiment, real spermaceti therefrom, of a slightly higher melting point than the cachalot sperm. Mr. Allen has published several communications concerning this oil, on which I may have more to say when we speak of oils proper.

I will now pass on to the vegetable waxes the importance of which entitles them to a brief consideration. There are four that may fairly be deemed regular visitors of the British markets. The first for beauty and purity, is *Chinese wax*, or *pela*.* This exquisite substance has a longitudinal crystalline fibre, much resembling pure stearine, and yet with something of the flakiness of sperm about it. It is a cerotic *ether*, having the seldom varying composition $\left.\begin{matrix}C_{27}H_{53}O\\C_{27}H_{55}\end{matrix}\right\}O$, cerotate of ceryl, corresponding to the true cerotic ether $\left.\begin{matrix}C_{27}H_{53}O\\C_2H_5\end{matrix}\right\}O$, or cerotate of ethyl. It melts at 180° F., and can be crystallized unchanged from boiling alcohol. The maker of this beautiful compound is a certain little insect, the *Coccus sinensis*, inhabiting China. The body of the grown insect varies in diameter from $\frac{1}{3}$-$\frac{2}{5}$ inch. Its cultivation demands as much care as that of the silkworm. The cocoons with eggs are attached carefully to certain trees. After a short time the young insects emerge, and commence operations on the bark; this speedily becomes covered with a white waxy film, in which the insects imbed themselves; the branches are then scraped carefully of the adhering crust, which is readily purified, by boiling, from the dirt and insects. Some portions of the wax, with the incerated chrysales, are kept for breeding purposes. The trees on which this insect feeds are for the most part, probably all, themselves wax producers. Its favourite pasture appears to be the *Rhus succedanea*, from the root of which Japan wax is obtained. This circumstance renders it doubtful whether the insect could produce wax upon any tree, given proper climate. My opinion is, that the wax is the result of a mutual understanding between the two—a product to which insect and tree are equally essential factors.

The amount of this wax realized is very large, averaging about 200 tons. This the Chinese consume all themselves, the price not allowing it to compete with equally useful English products. A little comes over now and then, but the sales are never large. Its chief use is to "break the grain" of spermaceti, the two crystallizations neutralizing each other; but as cheaper substances answer equally well, there cannot be much demand. But the Chinese, who eat all the animal fat they can get, are very glad of the material for their candles. Their *lobchocks* are made from it; this one is, quite characteristically, thicker at the top than the base, tapering downwards, and coloured bright scarlet.

Carnauba, or stone-wax.—This peculiar wax is intensely hard, and its melting point very high—too high for utility, as regards candles at least (185° F.). It is, however, I believe, used largely on the Continent as an adulterant or, perhaps legitimately, a hardening mixture, and enters largely into the composition of varnishes, heel-balls, etc. The colour varies from light yellow to deep grey green, and it can be bleached to an intense white. Carnauba wax is found adhering as a thin film, like varnish, to the leaves, stalks, and the berries especially, of a Brazilian palm, the *Copernicia cerifera*. From these the wax is boiled off, and skimmed into moulds. When congealed, its likeness to stone is so great that, were it not for the low sp. gr. (·999), one might easily class it with minerals. The composition of stone-wax is very uncertain. Lewy, a great authority on waxes, finds it to contain 80 per cent. of carbon; and Allen vouches for the presence of a notable

---

* Chinese, Chung-pih-la. Insect white wax.

quantity of free myricyl or melissic alcohol $\left.\begin{matrix}C_{30}H_{61}\\H\end{matrix}\right\}O$. The quantity produced is very large, but I am not in possession of trustworthy statistics.

The next, and last, of the true waxes is *myrtle wax* (myrica tallow). This soft green substance is formed on the berries of the *Myrica cerifera*, an American tree shrub. The berries grow in small clusters along the stem, and, when ripe, are covered with a tolerably thick rind of the wax, which is removed by boiling. This substance is also used chiefly in adulteration, though, from the very low melting point (123° F.), the use must be limited. The composition is chiefly palmitic and myristic acids, with a little glycerine, but has never been accurately determined. *Japan wax*, also called "tree wax," ought properly to rank as a fat, being a palmitate of glycerine, which latter it yields upon saponification. It is derived from the roots of several trees of genus *Rhus*, chiefly from the *Rhus succedanea* of the East Indies. The use of this wax as an adulterant is checked by its disagreeable odour—otherwise, it is a very useful substance; it enters largely into the composition of vegetable wax candles, much used as a substitute for those of genuine beeswax. Its sp. gr. is about ·999, the m.p. 120° F. There are several other waxes, of great use in their native countries, as *palm wax*, from the stem of the *Ceroxylon andicola*, Brazil, and *ocuba wax*, from the *Myrica ocuba* of the same country; also Andaquies wax, Cuba wax, and others of uncertain animal origin. The two first-named furnish a large portion of the candle power of northern South America.

I shall have to defer to next lecture the consideration of vegetable oils and fats, which are also very numerous. For the present, I will conclude with drawing your attention to this unique collection of all kinds of waxes, with a number of different candles with crude wicks, made by island savages as they best knew, for the most part of which I am indebted to the courtesy of Mr. Holmes, of the Pharmaceutical Society's Museum.

ROYAL INSTITUTION OF GREAT BRITAIN.

Some of the Questions involved in Solar Physics.*

BY SIR WILLIAM SIEMENS, D.C.L., LL.D., F.R.S., M.R.I.

The lecturer introduced his subject by drawing attention to the circumstance that the idea of the sun being an exceedingly hot body was of very modern date; that both ancient and modern writers up to the early portion of the present century attributed to him a glorious and supernatural faculty of endowing us with light and heat of the degree necessary for our well-being; whilst even Sir William Herschel had attempted to find an explanation in justification of the time-honoured conception that the body of the sun might be at a low temperature and inhabitable by beings similar to ourselves, which he did in surrounding the inhabitable surface by a non-conducting atmosphere—the penumbra—to separate it from the scorching influence of the exterior photosphere.

It was not till the views of Kant, the philosopher, had been developed by La Place, the astronomer, in his famous 'Mécanique Céleste,' that the opinion gained ground that our central orb was a mass of matter in a state of incandescence, representing such an enormous aggregate as to enable it to continue radiation into space for an almost indefinite period of time.

The lecturer illustrated by means of a diagram the fact that of all the heat raidiated away from the sun, only $\frac{1}{2250000000}$ part could fall upon the surface of our earth, vegetation and force of every kind being attributable to this radiation; whilst all but this fractional proportion apparently went to waste.

Recent developments of scientific research had enabled us to know much more of the constitution of the sun and other heavenly bodies than had formerly been possible. Comte says in his 'Positive Philosophy' (Martineau's translation of 1853) that "amongst the things impossible for us ever to know was that of telling what were the materials of which the sun was composed;" but within only seven years of that time Messrs. Bunsen and Kirchhoff published their famous research, showing that by connecting the dark Fraunhofer lines of the solar spectrum with the bright lines observed in the spectra of various metals, it was possible to prove the existence of those substances in the solar photosphere, thus laying the foundation of spectrum analysis, the greatest achievement of modern science. Dr. Huggins and others applying this mode of research to other heavenly bodies, including the distant nebulæ, had extended our chemical knowledge of them in a measure truly marvellous.

Solar observation had thus led to an analytical method by which chemistry had been revolutionized; and it would be, in the lecturer's opinion, through solar observation that we should attain to a much more perfect conception of the nature and effect of radiant energy in its three forms of heat, light and actinism, than we could as yet boast of. The imperfection of our knowledge in this respect was proved by the circumstance that whereas some astronomers and physicists, including Waterston, Secchi, and Ericsson, had, in following Sir Isaac Newton's hypothesis, attributed to the sun a temperature of several millions of degrees Centigrade, others, including Pouillet and Vicaire, in following Dulong and Petit, had fixed it below 1500° C. Between these two extremes, other determinations, based upon different assumptions, had fixed the solar temperature at between 60,000° and 9000°.

The lecturer having conceived a process by which solar energy may be thought to a certain extent self-sustaining, had felt much interested for some years in the question of solar temperature. If the temperature of the solar photosphere should exceed 3000° C., combustion of hydrogen would be prevented by the law of dissociation, as enunciated by Bunsen and Sainte Claire Deville; and his speculative views regarding thermal maintenance must fall to the ground. To test the question, he in the first place mounted a parabolic reflector on a heliostat with a view of concentrating solar rays within its focus, which, barring comparatively small losses by absorption in the atmosphere and in the metallic substance of the reflector, should reproduce approximately the solar temperature. By introducing a rod of carbon through a hole at the apex of the reflector until it reached the focus its tip became vividly luminous, producing a light comparable to electric light. When a gas burner was arranged in such a way that the gas flame played across the focal area, combustion appeared to be retarded, but was not arrested, showing that the utmost temperature attained in the focus did not exceed materially that producible in a Deville oxy-hydrogen furnace, or in the lecturer's regenerative gas furnace, in which the limit of dissociation is also reached.

Having thus far satisfied himself, his next step was to ascertain whether terrestrial sources of radiant energy were capable of imitating solar action in effecting the decomposition of carbonic acid and aqueous vapour in the leaf-cells of plants, which led him to undertake a series of researches on electro-horticulture, extending over three years, a subject he had brought before the Royal Society and the Royal Institution two years ago. By these researches he had proved that the electric arc possessed not only all the rays necessary to plant-life but that a portion of its rays (the ultra-violet) exceeded in intensity the effective limit, and had to be absorbed by filtration through clear glass, which, as Professor Stokes had shown, produced this effect without interference with the yellow and other luminous and intense heat rays. He next endeavoured to estimate the solar temperature by instituting a comparison between the spectra due to different known luminous intensities. Starting with the researches of

* Read Friday, April 27, 1883.

Professor Tyndall on radiant energy, supplementing them by experiments of his own on electric arcs of great power, and calling to his aid Professor Langley, of the Alleghany Observatory, to produce for him a complete spectrum of an Argand burner, he concluded that with the temperature of a radiant source, the proportion of luminous rays increased in a certain ratio; whereas in an Argand gas burner only $2\frac{1}{2}$ per cent. of the rays emitted were luminous and mostly red and yellow, the most brilliant portion of a gas flame emitted 4 per cent., as shown by Tyndall, the carbon thread of an incandescent electric light between 5 and 6 per cent., a small electric arc 10 per cent., and in a powerful 5000-candle electric arc as much as 25 per cent. of the total radiation was of the luminous kind. Professor Langley, in taking his photometer and bolometer up the Whitley mountains, 18,000 feet high, had proved that of the solar energy not more than 25 per cent. was luminous, and that the loss of solar energy sustained between our atmosphere and the sun was chiefly of the ultra-violet kind. These rays, if they penetrated our atmosphere, would render vegetation impossible, as proved by the lecturer's own experiments above referred to. It was thus shown that the temperature of the solar photosphere could not materially exceed that of a powerful electric arc, or, indeed, of the furnaces previously alluded to, leading him to the conclusion already foreshadowed by Sainte Claire Deville, and accepted by Sir William Thomson, that the solar temperature could not exceed 3000° C. The energy emitted from a source much exceeding this limit would no longer be luminous, but consist mainly of ultra-violet rays, rendering the sun invisible, but scorching and destructive of all life. A diagram of the spectra alluded to, which was exhibited by the lecturer, showed the gradual advance of the luminous band.

Not satisfied with these inferential proofs the lecturer had endeavoured to establish a definite ratio between temperature and radiation, which formed the subject of a very recent communication to the Royal Society.* The experiment consisted in heating, by means of an electric current, a platinum or iridio-platinum wire, a metre long, and suspended between binding screws; the energy of the current was measured by two instruments—an electro-dynamometer, giving it in ampères, and a galvanometer of high resistance giving the electromotive force between the same points in volts. The product of the two readings gave the volt-ampères, or Watts of energy communicated to the wire, and dispersed from it by radiation and convection. A reference to the lecturer's paper on the "Electrical Resistance Thermometer," which formed the Bakerian Lecture of the Royal Society in 1871, would show that the varying electromotive force in volts observed on the galvanometer was a true index of the temperature of the wire while being heated by the passage of the current. By combining his former experiments on the dependence of resistance upon temperature, with his recent one, a law of increase of radiation with temperature was established experimentally up to the melting-point of platinum; this, when laid down in the form of a diagram, gave very consistent results expressible by the simple formula—

$$\text{Rad}^{\text{tn}} = Mt^2 + \phi t$$

M being a coefficient due to substance radiating.

Sir William Thomson had lately shown that the total radiating energy from a unit of surface of the carbon of the incandescent lamp amounted to $\frac{1}{67}$th part of the energy emitted from the same area of the solar photosphere, and taking the temperature of the incandescent carbon at 1800° C. (the melting-point of platinum, which can just be heated to the same point), it follows in applying Sir William Thomson's deductions to the lecturer's formula that the solar photosphere does not exceed 2700° C., or, adding for absorption of energy between us and the sun about 2800° C., a temperature already arrived at by the lecturer by a different method. The character of the curve was that of a parabola slightly tipped forward, and if the ratio given by that curve held good absolutely beyond the melting-point of platinum, it would lead to the conclusion that at a point exceeding 3000° C. radiation would become, as it were, explosive in its character, rendering a surface temperature beyond that limit physically difficult to conceive.

Clausius had proved that the temperature obtainable in a focus could never exceed that of the radiating surface, and Sainte Claire Deville that the point of dissociation of compound vapours rises with the density of the vapour atmosphere. Supposing interstellar space to be filled with a highly attenuated compound vapour, it would clearly be possible to effect its dissociation at any point where, by the concentration of solar rays, a sufficient focal temperature could be established; but it was argued that the higher temperature observable in a focal sphere was the result only of a greater abundance of those solar vibrations called rays, within a limited area, the intensity of each vibration being the outcome of the source whence it emanated: thus, in the focal field of a large reflector the end of a poker could be heated to the welding-point, whereas in that of a small reflector the end of a very thin piece of wire only could be raised to the same temperature. If, however, a single molecule of vapour not associated or pressed upon by other molecules could be sent through the one focus or the other dissociation in obedience to Deville's law must take place irrespective of the focal area; but, inasmuch as the single solar ray represented the same potential of energy or period of vibration as numerous rays associated in a focus, it seemed reasonable that it should be as capable of dealing with the isolated molecule as a mere accumulation of the same within a limited space, and must therefore possess the same dissociating influence. Proceeding on these premises, the lecturer had procured tubes filled with highly attenuated vapours, and had observed that an exposure of the tubes to the direct solar rays or to the arc of a powerful electric light affected its partial or entire dissociation; the quantity of matter contained within such a tube was too slight to be amenable to direct chemical test, but the change operated by the light could be clearly demonstrated by passing an electric discharge through two similar tubes, one of which had, and the other had not, been exposed to the radiant energy from a source of high potential. If space could be thought filled with such vapour, of which there was much evidence in proof, solar rotation would necessarily have the effect of emitting such vapour equatorially by an action of circulation which might be likened to that of a blowing fan. When reaching the solar photosphere, by virtue of solar gravitation this dissociated vapour would, owing to its increased density, flash into flame, and could thus be made to account in great measure for the maintenance of solar radiation, whilst its continual dissociation in space would account for the continuance of solar radiation into space without producing any measurable calorific effect.

Time did not permit him to enter more fully on these subjects, which formed part of his solar hypothesis, his main object on this occasion having been to elucidate the point of cardinal importance to that hypothesis, that of the solar temperature.

INTERNATIONAL PHARMACEUTICAL EXHIBITION IN VIENNA.

Pharmaceutical Organization in Austria.

It is worthy of note that the first international pharmaceutical exhibition, which has just closed, was held in the capital of a country where the conditions under which pharmacy is carried on present many distinctive characters, and as the Catalogue of the Exhibition is prefaced by a few short chapters giving much interesting information upon the subject, the opportunity is a favourable one for laying before the readers of this Journal a brief account of the organizations connected with and regulating the practice of the art of pharmacy in the Austro-Hungarian empire. As is now almost universally the case to a greater or less degree in civilized countries the right of supplying medicines to the public is in Austria vested in persons possessing diplomas of qualification as pharmacists; but instead of admission to the body and registration being under the control of a central national authority, as is usually the case, they are here under the supervision of local chartered corporations, consisting of those pharmacists who are engaged in business in the district, and partaking somewhat of the nature of trade guilds or colleges. Such a corporation is termed the "Apotheker-Gremium" of the district, and the general management of pharmaceutical affairs in that district is in the hands of the President and Directors of this body, who are elected to their offices at regulated periods. Any pharmacist carrying on business must of necessity be a member of the Gremium of the district and must remain so as long as he continues in business there. If, however, he removes to another district his membership must be transferred to the Gremium of that locality.

As illustrating the character of these local corporations the Vienna Apotheker-Haupt-Gremium, although not the largest, may be referred to more in detail. Its early history, dating back for several centuries, cannot be traced with precision, its archives reaching back only to the year 1796. At the present time it consists of sixty-four members, and its business is conducted by two directors, assisted by a council of seven members. At least three meetings are held every year, at which reports upon the condition of affairs are presented, necessary votes are taken and any business of moment is discussed. The Register of owners of pharmaceutical establishments belonging to this Gremium dates back to the year 1796. The Register of pupils who have passed its examinations goes back to the same year, and in the interval of eighty-seven years, according to this Register, 526 pupils have been admitted into the Vienna Gremium, or on the average six in each year. The property of the Gremium consists of a library fund amounting to £300, which is augmented by the monthly subscriptions of members. All the best new publications connected with pharmacy are purchased, as well as the pharmaceutical and medical periodicals, together with old books for completing the library. The Benevolent Fund amounts to about £2200, which is partly invested in the offices of the Gremium and partly in a loan to the Austrian Apotheker-Verein. The interest of this fund, added to the annual subscriptions from the members, serve for casual relief as well as for pensions to aged members, their widows and orphans, and to incapacitated assistants of the Gremium or their widows. The annual income of the Gremium, consisting of the monthly subscriptions of the members, as well as the fees for registration of new members, as owners, lessees or managers, amounts to about £700. Out of this fund £20 is applied annually in the form of grants to industrious poor pharmaceutical students in the Vienna University, through the medium of the Vienna Pharmaceutical Society. In addition, the Gremium possesses a library of several thousand volumes and collections of minerals, drugs and herbaria, for the use of students. In connection with the Vienna Gremium there is a Mutual Sick Assurance Club, to which all the members belong.

One very important duty of the Vienna Gremium is that of providing the supply of medicines for the hospitals and public institutions upon the plan introduced by Dr. von Karajan. This duty has now been carried out since 1870 by the Gremium for the Imperial General Hospital, the Lunatic Asylum, the Lying-in Hospital, the Foundling and Orphan Asylums and the Wieden Hospital; and since 1871 for the Rudolph Hospital. The good results of this arrangement are evident from the fact that the Lower Austrian governmental departments and the directors of the three hospitals and associated institutions in that province entered into a contract with the Vienna Gremium for a supply of medicines for ten years. At the end of that period a new contract was entered into for three years, with a further provision for continuing the contract from year to year. Respecting the advantages of this arrangement, which is being further adopted by all the large institutions in Vienna, it may reasonably be expected that when a corporation such as the Vienna Apotheker-Haupt-Gremium undertakes the supply of medicines to public institutions, with the view of carrying it out less as a business than as an affair of honour, it will be impossible for the latter, all due allowance being made for the integrity of individual purveyors, to offer an equal guarantee for the proper execution of the work.

The two chief officers, as the representatives of the Gremium, have the conduct of this work, assisted by a committee consisting of ten members of the Gremium, but all the members of the Gremium participate equally in any resulting profit. Raw materials and the products of chemical factories are purchased wholesale, while strictly pharmaceutical as well as galenical preparations, and many of the more modern pharmaceutical articles, such as surgical dressings, are prepared on a large scale in the laboratory established for the purpose by the members of the Gremium in the pharmacy of the General Hospital. A thoroughly qualified and trustworthy staff carry out the details of the work so as to satisfy in a conscientious and economical manner the requirements of the hospital authorities and the medical officers of those institutions for the benefit of the patients and the credit of the pharmaceutical body.

At the present time there are in the Austrian empire about 1280 pharmaceutical establishments, the owners of which, except in the Tyrol and Dalmatia, are locally associated in such corporations as have here been already described. Each of these corporations has a president, who is chosen for three years. Regular meetings have to be held, and up to the end of the year 1874 they were attended by a Government commissioner. The business of the President of the Gremium is to represent the interests of pharmacy in relation to the various state authorities, to keep a register of its members, consisting of the owners, occupiers and managers of the pharmacies in the district; also a register of assistants and pupils, and to provide for their admission and examination. The President of a Gremium is also the person to whom Government decrees and other communications concerning its members are addressed. Besides the conduct of the finances, it is the business of the President to settle any disputes that may arise between members of a Gremium, and also to take part in the yearly inspection of pharmaceutical establishments.

The pharmacists are distributed throughout the different provinces of the empire as follows, and the numbers represent the extent of the Gremium in each case:—

Bohemia	324
Moravia	112
Silesia	36
Galicia	229
Bukowina	20
Styria	59
Carniola	21
Istria	32
Goertz	20
Carinthia	18
Tyrol	101
Vorarlberg	6
Salzburg	11
Upper Austria	59
Lower Austria	114
Vienna	64
Trieste	21
Dalmatia	33

The pharmaceutical establishments are of three kinds:—

(1) Those that can be disposed of unconditionally. All these date back prior to the year 1775, and their transfer from one owner to another had been officially recognized before that date.

(2) Those identified with a particular house, constituting a part of the house and its value, and therefore registered as such in the territorial records. These can only be transferred to another house by consent of those concerned and with the permission of the Government.

(3) Those which appertain to individuals and become extinct upon the death of the owner. In these cases, however, the widow may continue the business so long as she abstains from marrying again. The son has a preference in continuing the business only when his father was a citizen and when he has acquired the necessary qualifications. In any case a new concession is requisite, except in so far that for the benefit of the widow or of children under age the business may be carried on under the old concession, provided a qualified and responsible manager is appointed.

The oldest pharmaceutical establishments in the Austrian empire probably date back to the end of the thirteenth century, both in Vienna and in Prague. The establishment of new pharmacies in the larger towns took place gradually, but only by permission of the authorities, and since 1433 it has been a condition that the dispensatories according to which medicines were prepared, as well as the scale of charges, should be submitted to the Vienna faculty for approval. The first local association of pharmacists in the kind of college already described, was founded in Vienna, in 1457.

Pharmaceutical education in Austria is carried out in accordance with a Government decree of June, 1859. In order to obtain the degree of "Master of Pharmacy," which is necessary for the independent conduct of a pharmacy, the candidate must produce evidence of having passed the lower gymnasium course; also of having been engaged during three years as a pupil in a public pharmaceutical establishment, and of having passed the examination of the Gremium of his district; further, of having been an assistant during at least two years in a pharmacy, and, lastly, of having gone through the two years' pharmaceutical curriculum of an Austrian university and of having passed the three examinations connected with it satisfactorily. During the first session of the curriculum the candidate has to attend lectures upon elementary physics, mineralogy and general chemistry, extending over five hours every week. In the second session he must attend lectures on zoology, organic chemistry and botany. During the second year he has to attend lectures on pharmaceutical chemistry and pharmacognosy, and occupy himself in practical work in the laboratory for at least ten hours a week throughout the year. The first special examination, which has to be passed at the end of the first year's curriculum, is conducted by the professors, the subjects being elementary physics, zoology, botany and mineralogy. The chairman of the Board, consisting of four professors, is either the Dean, or the professor that has precedence of seniority. The examination lasts for a hour and an half. The second special (practical) examination, which can be passed in the last months of the second year's study, before the medical faculty, comprises the making of two pharmaceutical preparations under the supervision of the professor of chemistry and other members of the examining board. The carrying out of chemical analysis, qualitatively and quantitatively, the procedure adopted in these chemical operations and the results, have to be described by the candidate in the form of a written essay and submitted to the examiners. The examining board in this case consists of the President of the Medical Educational Faculty, the Professor of Chemistry, and, in Vienna as well as Prague, the Dean of the Faculty, while in other universities a practical pharmacist is especially nominated for this purpose. The third and last special examination includes pharmacognosy, general inorganic and organic chemistry, pharmaceutical chemistry and the laws affecting medicine and pharmacy. In pharmacognosy the candidate has to name several drugs, to recognize their quality, and mention their ordinary substitutions, impurities, and adulterations, and detect these if present. The examining board consists of the President of the Medical Educational Faculty, the Professor of Chemistry for pharmacists and of a pharmacist nominated for the purpose, or in Vienna and Prague, the Dean of the medical professors. This examination also lasts an hour and a half. In the reports on these examinations the candidates are grouped in three classes, as "qualified," "qualified with distinction" and "unqualified." When a candidate fails in one subject, he cannot present himself again for examination until the end of three months, and only after six months when he fails in two subjects. When he passes he is sworn and receives the diploma of "Master of Pharmacy."

In order to obtain the degree of "Doctor of Pharmacy" it is necessary to have obtained a higher grade in the public gymnasium, to have satisfied all the otherwise prescribed requirements as to pupillage and practical experience, to have attended the lectures for the "Master of Pharmacy," and to have passed the three special examinations with distinction; further, to have attended for a third year the lectures on general and pharmaceutical chemistry, to have given considerable attention to practical work, to have carried out two selected chemical operations as well as delivered a lecture upon them, and to have written a dissertation upon some chemical or similar subject. The chemical operations have to be begun by the candidate in the presence of the whole examining board, and completed under the supervision of the professors.

In addition to the above described organizations and educational regulations, which are compulsory, there are in Austria various associations connected with pharmacy which are of a voluntary character. First in order of importance is the General Austrian Apotheker-Verein, the institution of which is due to the late Professor Ehrmann, who, in 1827, conceived the idea of establishing a pharmaceutical laboratory, a technical journal and a body suitable for the better representation of the class and for the assistance of needy pharmacists. At that time the plan received no favourable countenance from the Apotheker-Gremiums, and it fell to the ground. Nevertheless, Dr. Ehrmann persevered in the attempt to carry out his views and in 1846 he received permission to publish a pharmaceutical journal. When the events of 1848 gave opportunity for the establishment of a free association in Austria, Dr. Ehrmann took advantage of the circumstance and in conjunction with his co-editor, Herr Sedlazek, again brought forward the proposition to establish a pharmaceutical society. His suggestion now received considerable support from those who recognized the utility and necessity of such a body, but nevertheless the Government authorities withheld their consent, on account of the state of siege under which Vienna was then placed. Somewhat later, Dr. Ehrmann again revived the subject at a meeting of the Olmutz Apotheker-Gremium and eventually the establishment of an association was sanctioned by the Moravian authorities about 1855, with Dr. Ehrmann as President and Herr Carl Schrotter as Vice-President. Many of the pharmacists in Lower Austria and Styria became members of this association, the objects of which were to promote the interests of the class, to furnish temporary assistance in cases of sickness or grant annuities such as would induce talented and useful individuals to devote themselves to the business, and to render assistance to widows and orphans of its members. After the Moravian Apotheker-Verein had continued in existence for some time it was resolved to apply to the Government to sanction the establishment of a General Austrian Apotheker-Verein. This was not granted at the time, but eventually the efforts made in this direction were successful, and in the year 1861 assent was given to the statutes drawn up for the regulation of such a society. The inauguration of this body took place the same year, in the Imperial Academy of Sciences in Vienna, the number of pharmacists who took part in its establishment as "founders" amounting to 84, while the number of ordinary members amounted to 176, including 48 assistants. The objects of this body were the same as those already mentioned in connection with the Moravian association, and it was proposed in addition to hold annual meetings affording opportunities for those outside the body to become acquainted with its proceedings. After some time, by the labours of its members, scientific collections were accumulated and premises were taken for their exhibition in Vienna, a journal also being published there, under the title of the "*Zeitschrift des allgemeinen österreichischen Apotheker-Vereines*," as the organ of the association. But in a short space of time the collections had increased to such an extent as to constitute a basis for the foundation of a School of Pharmacy, a project which was carried out by the establishment of a chemical laboratory, and after some further lapse of time, through the friendly co-operation of the Vienna Apotheker-Gremium, the premises which are now occupied by the association were purchased and adapted for its purposes, with the approval of the Minister of Religion and Education. The expenses attending upon this proceeding were provided for partly by a grant of £500 from the Government, and partly by donations from Austrian pharmacists. The establishment of the association now comprises a museum, a library, a lecture room, two laboratories, a hall for meetings, a botanic garden, and offices for the publication of the journal. The association at present consists of 70 honorary members, 50 corresponding members and 508 founders and ordinary members. The number of students attending the lectures in the school has risen from 12 in the year 1874–5 to 34 in the year 1882–3. The laboratory for study and analytical chemistry has been equally successful.

Another voluntary association is the Austrian Pharmaceutical Society, established with Government sanction in 1873, its object being to promote the interests of pharmacy in Austria and to improve the position of those belonging to the body by mutual intercourse, as well as to furnish assistance to needy members or their widows and orphans. The society is managed by a council, and in its general character and the nature of its proceedings bears a close resemblance to the British Pharmaceutical Conference. A weekly journal is published in connection with it under the title of the *Pharmaceutische Post*. In addition there are in Vienna two other associations of pharmacists, the "Hygeia," numbering 281 members, which is an association for rendering mutual assistance, and the Vienna Pharmaceutical Union, with 115 members, which is somewhat of the nature of a club. Another pharmaceutical association of a similar character, under the name of "Progressus," is situated in the town of Gratz.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from p.* 103.)

HYOSCYAMINÆ SULPHAS, U.S.P. (new).—The researches of Ladenburg have evidently been taken into account in respect to this salt. The formula adopted, $(C_{17}H_{23}NO_3)_2 \cdot HSO_4$, is the same as that for sulphate of atropine. The salt is described as occurring in "small golden-yellow or yellowish-white scales or crystals, or a yellowish-white amorphous powder, deliquescent on exposure to air;" whilst sulphate of atropine is "a white, indistinctly crystalline powder, permanent in the air." It may be remarked that, according to Ladenburg, in the free alkaloids these characters are reversed, hyoscyamine forming smaller or less perfect crystals than atropine (*Pharm. Journ.*, [3], x., 751). Hyoscyamine and its salts resemble atropine and its salts in many of their reactions, as in non-precipitation by a 5 per cent. solution of platinic chloride. The alkaloids differ however in respect to their gold salts; the precipitate obtained with atropine and chloride of gold, when recrystallized from boiling water acidulated with hydrochloric acid, forming minute crystals, becoming lustreless on drying, and that with hyoscyamine forming brilliant lustrous golden-yellow scales.

Iodinum, U.S.P.; Jodum, P.G.—In both works a ferrocyanide test has been inserted for the detection of a cyanide contamination, which is said to be sometimes derived from the protein substances of seaweed used in the manufacture.

Iodoformum, U.S.P. (new); P.G.—Iodoform was already contained in the P.G., and has now been included in the U.S.P. This is one of the many cases in which the "solubilities" given in the two works scarcely bear comparison. Thus although iodoform is not perceptibly soluble in water, the U.S.P. represents its solubility in "alcohol" containing 9 per cent. of water as 1 in 80, whilst the P.G. gives its solubility in a "spiritus" containing 4 per cent. more water as 1 in 50. In both works, too, the solubility in "ether" is given as 1 in 5·2, notwithstanding that the U.S.P. "ether" contains about 20 per cent. more alcohol than the P.G. "ether."

Lithium. Salts of.—In the P.G. only one salt of lithium, the carbonate, is official. The U.S.P., which previously, like the B.P., contained only the carbonate and the citrate, now includes five, the benzoate, bromide, carbonate, citrate and salicylate.

Lithii Benzoas, U.S.P. (new).—"A white powder or small shining scales, permanent in the air, odourless or having a faint benzoin-like odour, of a cooling and sweetish taste and a faintly acid reaction." Soluble in 4 parts of water and 12 parts of alcohol at 15° C., and 25 parts of boiling water and 10 parts of boiling alcohol. Under this salt tests are given for the residue after ignition, which are common also to the other organic salts of lithium. After the residue has been dissolved in dilute hydrochloric acid, filtered and evaporated to dryness, 1 part should be completely soluble in absolute alcohol, and the solution when ignited should burn with a crimson flame; the addition of an equal volume of stronger ether should not produce any precipitate (alkaline salts). Some of the residue dissolved in a small quantity of water should not give a precipitate with a 5 per cent. solution of oxalate of ammonia and should remain unaffected by hydrosulphuric acid, or sulphide of ammonium. It has been pointed out by Shuttleworth (*Pharm. Journ.*, [3], v., 682), that lithium benzoate can be obtained in crystals by setting aside the solution after decomposition of the carbonate with benzoic acid, instead of evaporating to dryness and powdering. The crystalline form, in flat elongated prismatic crystals containing one molecule of water, was adopted by the Paris Society in 1877 (*Pharm. Journ.*, [3], viii., 46).

Lithii Bromidum, U.S.P. (new).—A very deliquescent, white granular salt, very soluble in water and in alcohol. For methods of preparing it, see *Pharm. Journ.*, [3], vi., 22; viii., 46.

Lithii Carbonas.—The solubility of this salt in hot or cold water is given in the U.S.P. and the P.G. as 1 in 150, in the B.P. as 1 in 100.

Lithii Citras.—The U.S.P. still orders the anhydrous salt, defining it as a white deliquescent powder, notwithstanding that Sandford, Umney, and others have pointed out (*Pharm. Journ.*, [3], vi., 214) that it can now be conveniently produced in crystals that are not deliquescent.

Lithii Salicylas, U.S.P. (new).—This is described as a white deliquescent powder, odourless, or nearly so, having a sweetish taste and faintly acid reaction, and very soluble in water and alcohol.

Magnesia.—It will be remembered that hitherto in the U.S.P. and P.G. the official magnesia and carbonate have been the light forms. Heavy magnesia is now added in the U.S.P. under the title "magnesia ponderosa," the name "magnesia" being retained for what in the B.P. is called "magnesia levis." A recommendation in the preliminary Report to substitute the heavy varieties of both the oxide and the carbonate for the light has not been adopted.

Magnesii Citras Granulatus, U.S.P. (new); Magnesium Citricum Effervescens, P.G. (alt.).—These two preparations are practically the same. The U.S.P. directs 11 parts of magnesium carbonate to be mixed intimately with 33 parts of citric acid and enough distilled water to make a thick paste, which is to be dried at a temperature not exceeding 30° C., and then reduced to a fine powder. This is to be thoroughly mixed with 8 parts of powdered sugar, 37 parts of sodium bicarbonate, and 15 parts of citric acid previously reduced to a very fine powder. The whole is then moistened with sufficient alcohol, in which it is almost insoluble, and rubbed through a No. 20 tinned-iron sieve to form a coarse granular powder, which should be dried in a "moderately warm" place. The product is soluble, with copious effervescence, in 2 parts of water at 15° C. The alteration from the P.G., 1872, consists in a large increase in the proportion of the effervescing mixture.

Magnesii Sulphis, U.S.P. (new).—"A white crystalline powder." This is the form obtained by passing sulphurous oxide through water holding magnesium carbonate in suspension, and which was adopted by the Paris Society (*Pharm. Journ.*, [3], viii., 47). It can be obtained in larger crystals by a process of double decomposition, but it has been pointed out by Rother (*Pharm. Journ.*, [3], v., 544), that such crystals are dissolved with extreme slowness by water. The powder is soluble in 20 parts of water at 15° C.

Mangani Sulphas, U.S.P.; Manganum Sulfuricum, P.G. (new).—Sulphate of manganese, which was already in the U.S.P., has been added to the P.G. Peroxide of manganese has been dismissed from the P.G.

Morphine and Salts.—The U.S.P. retains the uncombined alkaloid and the acetate and hydrochlorate, but the acetate has been dismissed from the P.G. Both the U.S.P. and P.G. include the sulphate, the former giving its solubility in water at 15° C. (59° F.) as 1 in 24 (the same as that of the hydrochlorate), and the latter as 1 in 14·5 Mr. Dott, who recently discussed this question in an able paper (see vol. xiii., p. 401) gives the solubility in water at 60° F. of the hydrochlorate as 1 in 24, and of the sulphate as 1 in 23.

(*To be continued.*)

APPARATUS FOR SOLAR DISTILLATION.*

BY JOSIAH HARDING, M. INST. C.E.

The total absence of potable water in many parts of the world, to which the existence of valuable mineral deposits attracts a considerable population, has called for the invention of some artificial means of supplying this, the greatest of all the necessaries of life. Perhaps in no part of the world has more attention been given to the subject than in the northern part of Chile, "the desert of Atacama." This region was traversed by Indian posts in the time of the Incas, the runners being supplied with water at various points on the road, with an immense expenditure of labour. The water was carried long distances, in large earthenware jars; and the inconvenience was reduced to a minimum by the care bestowed in laying out the roads, so as to take the greatest advantage of the fresh-water springs at the foot of the Andes.

About thirty years since the method of procuring fresh water from the sea by distillation was commenced. The original form of apparatus, and one that is even now largely in use, consisted merely of a Cornish boiler, the steam from which passed through a coil of wrought-iron pipes in an open tank, often of wood. Various improvements have been made from time to time, principally in the direction of enclosing the coils and conducting the steam given off to secondary, and thence to tertiary, condensers, similar to the apparatus designed by the late Dr. Normandy. The ordinary consumption of coal per unit of water in the original open condensers is about one-sixth, but with several condensers and an air-pump on the last, a ratio of one-sixteenth is regularly obtained in daily work.

A serious inconvenience attending this method of production arises from the excessively bad quality of the water for use in a steam boiler, as it contains about 14 per cent. of salts—the principal of which are chloride of sodium and the sulphates of lime, soda, and magnesia. The freight on coals from the port, too, is enormous, amounting, at the time when the apparatus was designed, to from three to three and a half dollars per hundred pounds. Taking into consideration the loss on the road, and the expense of repairs to boilers, condensers, etc., the cost of water was about four cents per gallon.

With a view to overcoming this difficulty, an apparatus for the distillation of water in Las Salinas, by the action of the sun's rays, was designed by Mr. Charles Wilson in 1872. Las Salinas is situated about seventy miles inland from the port of Antofogasta, and is about half-way on the road to Caracoles, a great silver district, requiring, when in full work, the employment of about eight hundred carts and four thousand mules, which passed through Salinas, on an average, about once a week. The site selected for the establishment was a smooth plain, with an inclination of about 1 in 100 towards the old watercourse, in which are wells for salt water. The apparatus consists essentially of a number of long shallow troughs, filled with water, and covered by a sloping glass roof. The water is evaporated by the sun's rays passing through the glass; the vapour is condensed on the under surface of the glass, runs down to grooves cut in the wooden frame, and thence, by a system of pipes, to the fresh-water tank. There are in the establishment at Salinas sixty-four frames, each 200 feet long by 4 feet broad, giving a total area of 51,200 square feet of glass. Each frame is composed of two principal parts, the water-trough and the roof. The trough is constructed of three longitudinal sleepers, 4 inches by 4 inches, of which the planking ($1\frac{1}{2}$ inch thick) is laid. The sides are composed of timbers, bolted to the sleepers at every 6 feet, the whole being carefully jointed inside with putty, to render it perfectly watertight, and having an inclination of about 1 inch in the total length in the direction of the wash-out plug. The roof is constructed in ten lengths of 20 feet each. The sides are of pine, with the upper edge properly cut to receive the glass, and a groove for conveying the condensed water to the outlet-pipes, which are placed at the lower end of each section, the groves having an inclination of 2 inches in 20 feet, in addition to the inclination of the trough. The end frames of the 20-feet sections of the roof, excepting those which coincide with the ends of the troughs, are carried down to a little below the water-level, to prevent the escape of vapour in the joint, there being, in fact, no outlet for the vapour, excepting by the small lead pipes which carry off the condensed water. The ridge is supported by the end frames and intermediate uprights, resting on the bottom of the trough. The sash-bars are movable, so as to suit varying widths of glass.

The salt water is admitted by a 1-inch brass cock at the higher end of the trough, and a wooden plug for washing out is provided at the lower end. There is also, at the lower end, an overflow pipe, the point of which is turned down below the water, to prevent the escape of vapour. The salt water is pumped from the wells by a windmill into a tank at the upper end of the grounds, sufficiently large to contain about four days' supply. The water from the tank is distributed to the various troughs by a 2-inch wrought-iron pipe, with the necessary connections. The fresh water is collected from the small lead pipes into a $1\frac{1}{2}$-inch wrought-iron pipe running between the troughs, and connecting with a 2-inch main-pipe at the end, which leads to the storage tanks. To increase the evaporation, the bottoms of the troughs are blackened with logwood and alum, and are washed out every second day, by running salt water through them.

When first set to work, the establishment produced daily, in summer, upwards of 5000 gallons of fresh water, about equal to 1 lb. of water per square foot of glass; but after the opening of the railway the owners grew careless, and allowed the troughs to get out of repair, so that, through leakages and insufficient cleansing, the production gradually fell off to about one-half of the above. When not properly attended to, crystals of sulphate of soda and lime (Glauberite) form in the troughs, directly diminishing the production, and indirectly leading to loss by leakage when the crystallization takes place between the planks, and so forcing open the joints. When properly maintained, the cost of water, including interest on capital, renewals of glass, etc., amounted to less than 1 per cent. per gallon. The principal item of expense is the renewal of glass broken by whirlwinds, which are very frequent in the locality. The staff consists of a clerk, who keeps the accounts, sells the water, and manages the business generally; and of a glazier, and two labourers for cleaning and repairs, and at intervals a carpenter to restore the woodwork.

The frames being laid on the ground, it is difficult to discover a leak, and the wood in the sides of the roof, between the fresh-water groove and the salt water is apt to crack in the part above the level of the salt water, and cause a loss of fresh water by its leaking back into the trough. The first defect could be remedied, at a moderate cost, by raising the longitudinal timbers on cross-sleepers placed 4 or 5 feet apart, and the second defect by lining the grooves with thin sheet-lead or tin. In the warm vapour under the glass, iron is very quickly destroyed. The temperature of the water in the troughs at noon (when the thermometer stands at 80° in the shade), is from 140° to 150° Fahrenheit. The distillation usually begins at about 10 a.m. and ends at about 10 p.m.

Some experiments were made, but very incompletely, to try the effect of warming the water in a boiler before it entered the troughs, especially for use during the night and early morning. From the little that was done, it appeared probable that good results might be expected. On cloudy days the production is less than one-half, about 40 per cent., of that on sunny days Cloudy days are, however, very rare.

* Abstract of a paper read before the Institution of Civil Engineers.

The total cost of the establishment, with pumps, windmills and tanks, was about 50,000 dollars, or 1 dollar per square foot of glass. This is much more than it would have been if the glass had been ordered direct from England, as in that purchased on the coast the broken glass is more than 50 per cent. of the whole. The freight on the material was a very large item; but, unfortunately, no details of the expenditure of the capital exist. An approximate estimate of the cost of such an establishment, under similar conditions, would be about 80 cents for each pound of water required daily.

Las Salinas is about 4300 feet above sea-level, and, from experiments tried in various parts, it is found that the water produced per foot of glass increases with the height above the sea. On the coast the production is about 25 per cent. less than in Salinas, probably in some degree owing to the greater number of cloudy days.

THE ATTACHMENT AND BITE OF THE LEECH.

BY G. CARLET.

The generally received opinion respecting the mechanism of the attachment of the leech is in accordance with the statement of Moquin-Tandon, that when the leech wishes to apply its oral sucker, it first projects the centre of it as a kind of cushion against the body it has chosen; then lowering the edges of the sucker from within outward, it finishes by solidly fixing the whole of its surface, and that an almost similar action takes place with the anal sucker.*

This mechanism has been studied by placing leeches on a glass plate and examining, through the glass, what occurs at the moment of application of the suckers. It has been found, however, by M. Carlet,† that this method of observation, though it might seem quite rational, does not give good results, because of the rapidity with which the attachment is effected; indeed, if the observers had waited until the leech had lost a little of its power of adherence, it would have been seen that the attachment of the suckers was not made in so complete a manner, and that one or more bubbles of air remained in the centre of each sucker, which would not have occurred if the centre had been fixed before the sides.

In studying the question afresh M. Carlet has had recourse to a graphic method. If a leech is placed on a piece of smoked paper, it advances, as on other surfaces, by the application of its two suckers, which serve it alternately as points of support. He has found it possible with care, to make the animal itself register the series of acts involved, and describes them as follows:—

A. The fixing of the posterior sucker is made very simply and quickly, first by the contact of the periphery, which describes on the blackened paper a white circle round a black disc, then by the lowering of the centre of the sucker, which adheres to the paper and causes the black spot to disappear.

B. The fixing of the anterior sucker is made in a much more complicated manner and less quickly.

(1.) The leech begins by exploring the place where it intends to fix itself with the two edges of the upper lip; these impress in white on the blackened paper, so as to form two lines converging forward.

(2.) The anterior part of the upper lip is lowered, and is seen to design a curvilinear angle opening backward.

(3.) The lower lip is then applied to the blackened surface, producing a curvilinear angle with a black centre.

(4.) The pharynx begins to be lowered and the triangular contour of the sucker widens in taking the circular form, so as to trace upon the paper a white circle, the centre of which remains black, showing that there has not yet been any contact with the centre of the sucker.

(5.) Lastly, the sucker touches the paper with its centre, and the complete adhesion is shown by an entirely white circle.

Instead, therefore, of beginning by fixing the centre of the sucker, and afterwards lowering the edges of that organ, as has been assumed without sufficient proof, the leech begins by fixing the edges, and afterwards lowering the centre, which adheres last. The detachment, which commences at the edges, finishes at the centre of the sucker.

M. Carlet has also been engaged in studying the bite of the leech, about which little was known beyond the fact that it is effected by means of three denticulated jaws of which the anatomy alone has been well studied.

According to M. Carlet,* immediately after the attachment, the anterior part of the body of the leech is brusquely erected so as to simulate a horseshoe posed on the ground. This position, which immediately precedes the bite, is obtained by the contraction of the longitudinal muscular fibres of the raised part, which serves then as a point of support to the muscles of the jaws. As soon as these enter into action they are seen to proceed by three projections, then three depressions, which succeed each other with perfect regularity.

Direct observation of these movements may be made upon compressing lightly the pharyngeal region between two fingers. M. Carlet has succeeded in making them register themselves, and has thus ascertained that they follow each other, without cessation, at the rate of two contractions a second.

In order to study the mode by which the bite is effected M. Carlet applied some leeches to the shaved skin of a rabbit, and by detaching them from it at various times was enabled to make the following observations:—

(1.) Upon carefully raising, by means of a hook, a point of the circumference of the sucker as soon as the part surmounting it was erected, it was seen that the skin was like a teat, and upon complete removal of the leech it was seen that this teat had not yet been punctured. This phase, which the author calls the preliminary stage of the bite, has no relation to the attachment, for, if a leech is made to progress on a leaf of very thin paper no indentation can be perceived under the paper corresponding to the attachment of the suckers.

(2.) If the leech were detached immediately after the movements of the pharyngeal region had given the signal of the action of the jaws, there were found on the skin three unconnected equidistant linear incisions.

(3.) If the leech were not detached until some moments after the commencement of the bite, three rents were observed, figuring a trefoil, the folioles of which were not in contact with each other. If, at the same moment, instead of the leech being detached, it was divided with a cut of the scissors in the œsophagal region, it did not cease to bite, but there was no immediate outflow of blood by the œsophagal orifice.

(4.) If this fragment of the leech, which continued to bite, were detached as soon as the blood commenced to escape by the section of the œsophagus, it was seen that the three folioles of the trefoil had joined together in the centre, so as to produce, by drawing back the shreds of the skin, a wound having the form of a triangle, the three medians of which correspond to the three jaws.

(5.) It was possible sometimes, when a leech was in the act of biting, to raise a portion of the sucker long enough to be able to observe the movement of the jaws easily. These were then seen to turn away one from the other at the same time that they penetrated into the wound, and afterwards to approach each other as they were raised.

To sum up, the denticules of the jaws are not strong enough to produce at a single cut a wound which causes the blood to flow and they act by many repetitions. They may be compared to a scarificator with three equidistant dentate blades, which turn away one from the other at the same time that they penetrate the skin. In making the instrument work several times successively in the same place, a sufficiently exact idea of the pharyngeal armature and of the mechanism of the bite of the leech may be obtained.

The Pharmaceutical Journal.

SATURDAY, AUGUST 25, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

A PROPOSAL FOR THE ESTABLISHMENT OF TECHNICAL JURIES.

THE report of the litigation between the Baden Aniline and Soda Manufacturing Company and Messrs. LEVENSTEIN, which was published in a recent number of this Journal, furnishes an illustration of a class of cases that must be always a source of considerable perplexity to the judges who have to try them. In the majority of cases which come into the law courts a just decision depends upon the application of well-defined principles of law to facts which, however much obscured by prejudice and misrepresentation, are familiar in kind to and therefore easily weighed by the judicial mind when once established. But in technical disputes, where the import and bearing of the facts deposed to by witnesses can only be properly estimated by experts, and are certainly frequently unappreciated and misunderstood even by the counsel for the litigant on whose behalf they were put forward, judges have undoubtedly a much more difficult problem to solve before they can arrive at a correct decision. Take for instance the case referred to, where the point in dispute was the infringement of a patent protecting certain processes for the production of the "sulpho acids of oxyazonaphthalene," a subject concerning which many chemists even would be unprepared to speak without previously reading it up. After a considerable number of scientific witnesses had been heard the learned judge sought to help himself to light upon one point that appeared to lend itself to ocular demonstration; but even here he was foiled, and felt compelled to call in Professor ROSCOE to his aid. Nevertheless, the learned judge had apparently to base his decision eventually upon his ability to recognize nice shades of resemblance or distinction between chemical reactions, of which, it is not disrespectful to say, he probably had no conception before the trial began.

But this inconvenience, which probably could hardly be overcome without a wide extension of the utilization of assessors, is greatly intensified, when, as is sometimes the case, the questions of fact that might perplex the trained intellect of a judge have to be pronounced upon by the ordinary special juryman. Nor is there a probability that it will become more infrequent now that scientifically worked out processes are so widely displacing the rule of thumb in every important manufacture. It has been pointed out that in such cases the members of a jury, when they agree upon a verdict, are more likely to be unduly influenced by the counsel who can make his points clear to them, or by an opinion expressed by the judge, than in cases where little or no technical knowledge is required. Hence the number of such verdicts that are reversed on appeal, and the growing tendency of suitors to avoid this risk by adopting one of the alternative procedures either before a judge sitting without a jury or by arbitration. Probably both of these modes present points of advantage, though, from the causes before mentioned, the plan of leaving the decision to a single judge cannot be deemed altogether satisfactory, and those who have had many of such cases under their notice must have been struck with the tendency shown by judges themselves to break through the web woven around them by experts, and to give a premature decision upon a point of law, whilst it cannot be said that the public has yet been educated to the point of placing, as a rule, as much confidence in arbitrators as in juries.

The subject has been fairly discussed in a communication recently submitted by Mr. EWING MATHESON to the London Chamber of Commerce, in which he recommends the formation of a class of technical jurymen or assessors, and the establishment of properly organized courts of arbitration. Neither of these suggestions has all the charms of novelty, but we think they are worthy of a fuller consideration than they have yet received, and upon the former especially, most of the readers of this Journal are very well qualified to pronounce an opinion. In dealing with the primary question as to how a better class of jurymen is to be obtained, Mr. MATHESON argues that the difficulty does not lie in any lack of the class of men required, either in London or other important centres, but rather in the mode of selecting them so as to best secure the confidence of suitors and not to press too hard upon the jurymen themselves. The classes which he would propose to utilize in the organization of a body of technical jurymen would be the members of those learned societies, membership of which implies more than an amateur knowledge, as distinguished from those that can be entered by payment of a fee, and university graduates in science. Mr. MATHESON evidently looks with longing eyes upon the members of the medical profession, who would from their training form admirable technical jurymen; but he recognizes that their avocation forbids their being called upon, and we may remark that the same exemption would apply in the case of the many pharmaceutical chemists who are members of the learned societies. He thinks, however, that it would be worth considering whether those engaged in certain kinds of practice, an interruption of which would inconvenience only themselves, and those who had retired from practice, might not be included in a technical jury list with very great advantage to the community. We should have more faith in this suggestion if it indicated more clearly that the service should be optional, rather than dependent upon some arbitary distinction between members of the same class.

It is thought that from the classes above indicated a body of ten thousand technical jurymen might be selected, or, allowing for deductions on account of age, infirmity and absence, a panel of at least five thousand men might be secured, and assuming an average of one hundred trials yearly in which the services of such jurymen would be required, the plan would involve service once every five years. It is not proposed that all the members of a jury shall be specially interested in the science bearing on the case,—for instance, that disputes about engineering patents shall be settled by a jury of engineers, or electric light contentions by a jury of electricians,—it being thought that the wider basis and variety of a jury made up of the various classes would be an advantage, whilst each member would possess in his own training a special fitness for comprehending the arguments in a technical dispute.

It will be evident, however, that before such a scheme could be brought within the range of practical politics many points will have to be settled, amongst others whether technical jury service should be compulsory or voluntary, whether it should be considered supplemental to or an equivalent for ordinary jury service, and whether it should be specially remunerated. The scheme will have to experience the preliminary winnowings and siftings that fall to the lot of all projected improvements, and it is quite possible, notwithstanding a certain amount of merit, that it may disappear in the process.

The Medical Acts Amendment Bill was on Wednesday last withdrawn by the Government. It had been hoped that the second reading would have taken place on Tuesday and in that case it was intended to have proceeded with the Bill. But it was not reached on that day, and on the next, in reply to questions, the Premier said that the loss of the opportunity was fatal to the chances of the Bill passing this session, and later in the evening the order for the second reading was read and discharged.

* * *

The clause submitted by the Board of Trade to the Council of the Society at its last meeting was incorporated into the Patents for Invention Bill which has since passed through Parliament. In reply to a question in the House of Commons on Monday last, the Solicitor-General stated that tradesmen who displayed the Royal Arms on trade labels, shop fronts and in other ways, but without any word or words implying that they made such assumption by authority would not render themselves liable to penalty under that clause.

* * *

The Select Committee on the Petroleum Bill has reported to the House of Lords recommending its withdrawal. The Committee is of opinion that the evidence it has collected will enable the Home Office in the early part of next session to present such a Bill as will provide for the safety of the public.

* * *

A revised Circular of Instructions to Superintendents of Mercantile Marine Offices respecting the Medical Scale for Merchant Ships has recently been issued by the Board of Trade. The principal alteration from the previous Scale consists in the incorporation of a "Scale of Medical Comforts," giving the quantities to be shipped for every hundred passengers where the length of the passage is one hundred days, or upwards. One half these quantities have to be shipped when the length of the passage is under that time. In the Scale of Medicines two fresh articles have been introduced, "Red Cross Antiseptic Fluid," and "Cerealine." Although the nature of those two articles may be guessed at, the names appear to indicate that they are specialties of particular manufacturers. We think this to be greatly regretted; for all the articles in a compulsory list like this should be sufficiently defined under recognized names that disclose their composition to enable them to be readily identified and supplied.

* * *

According to a statement in the *British Medical Journal* twenty-six baronetcies have been conferred upon members of the medical profession during the last hundred years, namely four by George III., two by George IV., two by William IV., and eighteen by our present Queen. Four of these have already become extinct. Of the eighteen medical baronets created during the present reign, and of whom eight survive, eleven were physicians, five were surgeons, and two obstetric physicians. All the eight medical baronets now living practise in London.

* * *

According to a report by Mr. Consul Cameron the crop of bark from the Dutch Government cinchona plantations in Java is increasing year by year, that for 1882 amounting to 230,000 Amsterdam pounds (17½ ounces nearly) against 165,000 pounds in 1881. Experiments made last year to ascertain the percentage of alkaloid contained in the bark from young Ledgeriana trees raised from seed produced by plants grown in the island showed that the bark from a plant four years old, when bearing the true type of the mother stem, yields 9 to 11·75 per cent. of quinine, being an improvement on the parent trees. There were at the end of the year 3,305,200 cinchona trees in the Government nurseries and plantations, of which 820,700 were young Ledgeriana trees in the nurseries, and 694,900 older ones in the plantations. The exports of bark from the private plantations in Java during 1882 was 181,354 Amsterdam pounds, a quantity that is likely soon to be considerably increased.

We regret to have to record the death at Dorchester, on the 4th inst., of Mr. T. W. H. Tolbort, who was one of the earliest "Bell Scholars," he having been chosen, together with Dr. Tilden, at the institution of the Jacob Bell Memorial Scholarships, in 1861. Mr. Tolbort did not, however, continue long in the ranks of pharmacy, but having shortly afterwards passed the Indian Civil Service Examinations at the head of the list, he entered the Bengal Civil Service, and at the time of his death held the office of Deputy Commissioner at Umballa.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.

Thoughts on Radiation, Theoretical and Practical.*

BY PROFESSOR TYNDALL, D.C.L., F.R.S., M.R.I.

Scientific discoveries are not distributed uniformly in time. They appear rather in periodic groups. Thus, in the two first years of this century, among other gifts presented by men of science to the world, we have the Voltaic pile; the principle of Interference, which is the basis of the undulatory theory of light; and the discovery by William Herschel of the dark rays of the sun.

Directly or indirectly, this latter discovery heralded a period of active research on the subject of radiation. Leslie's celebrated work on the Nature of Heat was published in 1804, but he informs us, in the preface, that the leading facts which gave rise to the publication presented themselves in the spring of 1801. An interesting but not uncommon psychological experience is glanced at in this preface. The inconvenience of what we call ecstacy, or exaltation, is that it is usually attended by undesirable compensations. Its action resembles that of a tidal river, sometimes advancing and filling the shores of life, but afterwards retreating and leaving unlovely banks behind. Leslie, when he began his work, describes himself as "transported at the prospect of a new world emerging to view." But further on the note changes, and before the preface ends he warns the reader that he may expect variety of tone, and perhaps defect of unity in his disquisition. The execution of the work, he says, proceeded with extreme tardiness; and as the charm of novelty wore off, he began to look upon his production with a coolness not usual in authors.

The ebb of the tide, however, was but transient; and to Leslie's ardour, industry and experimental skill, we are indebted for a large body of knowledge in regard to the phenomena of radiation. In the prosecution of his researches he had to rely upon himself. He devised his own apparatus, and applied it in his own way. To produce radiating surfaces, he employed metallic cubes, which to the present hour are known as Leslie's cubes. The different faces of these cubes he coated with different substances, and filling the cubes with boiling water, he determined the emissive powers of the substances thus heated. These he found to differ greatly from each other. Thus, the radiation from a coating of lampblack being called 100, that from the uncoated metallic surface of his cube was only 12. He pointed out the reciprocity existing between radiation and absorption, proving that those substances which emit heat copiously absorb it greedily. His thermoscopic instrument was the well-known differential-thermometer invented by himself. In experiment Leslie was very strong, but in theory he was not so strong. His notions as to the nature of the agent whose phenomena he investigated with so much ability are confused and incorrect. Indeed, he could hardly have formed any clear notion of the physical meaning of radiation before the undulatory theory of light, which was then on its trial, had been established.

A figure still more remarkable than Leslie occupied the scientific stage at the same time, namely, the vigorous, original and practical Benjamin Thompson, better known as Count Rumford, the originator of the Royal Institution. Rumford traversed a great portion of the ground occupied by Leslie, and obtained many of his results. As regards priority of publication, he was obviously discontented with the course which things had taken, and he endeavoured to place both himself and Leslie in what he supposed to be their right relation to the subject of radiant heat. The two investigators were unknown to each other personally, and their differences never rose to scientific strife. There can hardly, I think, be a doubt that each of them worked independently of the other, and that where their labours overlap, the honour of discovery belongs equally to both.

* Read Friday, March 16, 1883.

The results of Leslie and Rumford were obtained in the laboratory; but the walls of a laboratory do not constitute the boundary of its results. Nature's hand specimens are always fair samples, and if the experiments of the laboratory be only true, they will be ratified throughout the universe. The results of Leslie and Rumford were in due time carried from the cabinet of the experimenter to the open sky by Dr. Wells, a practising London physician. And here let it be gratefully acknowledged that vast services to physics have been rendered by physicians. The penetration of Wells is signalized among other things by the fact recorded by the late Mr. Darwin, that forty-five years before the publication of the 'Origin of Species,' the London doctor had distinctly recognized the principle of Natural Selection, and that he was the first to recognize it. But Wells is principally known to us through his 'Theory of Dew,' which, prompted by the experiments of Leslie and Rumford, and worked out by the most refined and conclusive observations on the part of Wells himself, first revealed the cause of this beautiful phenomenon. Wells knew that through the body of our atmosphere invisible aqueous vapour is everywhere diffused. He proved that grasses and other bodies on which dew was deposited were powerful emitters of radiant heat; that when nothing existed in the air to stop their radiation, they became self-chilled; and that while thus chilled they condensed into dew the aqueous vapour of the air around them. I do not suppose that any theory of importance ever escaped the ordeal of assault on its first enunciation. The theory of Wells was thus assailed; but it has proved immovable, and will continue so to the end of time.

The interaction of scientific workers causes the growth of science to resemble that of an organism. From Faraday's tiny magneto-electric spark, shown in this theatre half a century ago, has sprung the enormous practical development of electricity at the present time. Thomas Seebeck, in 1822, discovered thermo-electricity, and eight years subsequently bars of bismuth and antimony were first soldered together by Nobili so as to form a thermo-electric pile. In the self-same year Melloni perfected the instrument and proved its applicability to the investigation of radiant heat. The instrumental appliances of science have been well described as extensions of the senses of man. Thus the invention of the thermopile vastly augmented our powers over the phenomena of radiation. Melloni added immensely to our knowledge of the transmission of radiant heat through liquids and solids. His results appeared at first so novel and unexpected that they excited scepticism. He waited long in vain for a favourable report from the academicians of Paris; and finally, in despair of obtaining it, he published his results in the *Annales de Chimie*. Here they came to the knowledge of Faraday, who, struck by their originality, brought them under the notice of the Royal Society, and obtained for Melloni the Rumford medal. The medal was accompanied by a sum of money from the Rumford fund; and this, at the time, was of the utmost importance to the young political exile, reduced as he was to penury in Paris. From that time, until his death, Melloni was ranked as the foremost investigator in the domain of radiant heat.

As regards the philosophy of the thermopile, and its relation to the great doctrine of the conservation of energy, now everywhere accepted, a step of singular significance was taken by Peltier in 1834. Up to that time it had been taken for granted that the action of an electric current upon a conductor through which it passed, was always to generate heat. Peltier, however, proved that, under certain circumstances, the electric current generated cold. He soldered together a bar of antimony and a bar of bismuth, end to end, thus forming of the two metals one continuous bar. Sending a current through this bar, he found that when it passed from antimony to bismuth across the junction, heat was always there developed, whereas when the direction of the current was from bismuth to antimony, there was a development of cold. By placing a drop of chilled water upon the junction of the two metals, Lenz subsequently congealed the water to ice by the passage of the current.

The source of power in the thermopile is here revealed, and a relation of the utmost importance is established between heat and electricity. Heat is shown to be the nutriment of the electric current. When one face of a thermopile is warmed, the current produced, which is always from bismuth to antimony, is simply heat consumed and transmuted into electricity.

Long before the death of Melloni, what the Germans call "Die Identitäts Frage," that is to say, the question of the identity of light and radiant heat, agitated men's minds and spurred their inquiries. In the world of science people differ from each other in wisdom and penetration, and a new theoretic truth has always at first the minority on its side. But time, holding incessantly up to the gaze of inquirers the unalterable pattern of nature, gradually stamps that pattern on the human mind. For twenty years Henry Brougham was able to quench the light of Thomas Young, and to retard, in like proportion, the diffusion of correct notions regarding the nature and propagation of radiant heat. But such opposing forces are, in the end, driven in, and the undulatory theory of light being once established, soon made room for the undulatory theory of radiant heat. It was shown by degrees that every purely physical effect manifested by light was equally manifested by the invisible form of radiation. Reflection, refraction, double refraction, polarization, magnetization, were all proved true of radiant heat, just as certainly as they had been proved true of light. It was at length clearly realized that radiant heat, like light, was propagated in waves through that wondrous luminiferous medium which fills all space, the only real difference between them being a difference in the length and frequency of the ethereal waves. Light, as a sensation, was seen to be prodnced by a particular kind of radiant heat, which possessed the power of exciting the retina.

And now we approach a deeper and more subtle portion of our subject. What, we have to ask, is the origin of the ether waves, some of which constitute light, and all of which constitute radiant heat? The answer to this question is that the waves have their origin in the vibrations of the ultimate particles of bodies. But we must be more strict in our definition of ultimate particles. The ultimate particle of water, for example, is a *molecule*. If you go beyond this molecule and decompose it, the result is no longer water, but the discrete *atoms* of oxygen and hydrogen. The molecule of water consists of three such atoms tightly held together, but still capable of individual vibration. The question now arises: Is it the molecules vibrating as wholes, or the shivering atoms of the molecules that are to be considered as the real sources of the ether waves? As long as we were confined to the experiments of Leslie, Rumford, and Melloni, it was difficult to answer this question. But when it was discovered that gases and vapours possessed—in some cases to an astonishing extent—the power both of absorbing and radiating heat, a new light was thrown upon the question.

You know that the theory of gases and vapours, now generally accepted, is that they consist of molecular or atomic projectiles darting to and fro, clashing and recoiling, endowed, in short, with a motion not of vibration but of translation. When two molecules clash, or when a single molecule strikes against its boundary, the first effect is to deform the molecule, by moving its atoms out of their places. But gifted as they are with enormous resiliency, the atoms immediately recover their positions, and continue to quiver in consequence of the shock. Held tightly by the force of affinity, they resemble a string stretched to almost infinite tension, and therefore capable of generating tremors of almost infinite rapidity. What we call the heat of a gas is made up of these two motions—the flight of the molecules through space, and the quivering of their constituent atoms. Thus does the eye of science pierce to what Newton called "the more secret and noble works of Nature," and make us at home amid the mysteries of a world lying in all probability vastly further beyond the range of the microscope than the range of the microscope, at its maximum, lies beyond that of the unaided eye.

The great principle of radiation, which affirms that all bodies absorb the same rays that they emit, is now a familiar one. When, for example, a beam of white light is sent through a yellow sodium flame, produced by a copious supply of sodium vapour, the yellow constituent of the white beam is stopped by the yellow flame, and if the beam be subsequently analysed by a prism, a black band is found in the place of the intercepted yellow band of the spectrum. We have been led, as you know, to our present theoretic knowledge of light by a close study of the phenomena of sound, which in the present instance will help us to a conception of the action of the sodium flame. The atoms of sodium vapour synchronize in their vibrations with the particular waves of ether which produce the sensation of yellow light. The vapour, therefore, can take up or absorb the motion of those waves, as a stretched piano-string takes up or absorbs the pulses of a voice pitched to the note of the string. I will now show you the action of sodium vapour, in a way and with a result which startled and perplexed me on first making the experiment, more than twenty years ago. You know that the spectra of incandescent metallic vapours are not continuous, but formed of brilliant bands. I wished, in 1861, to obtain the brilliant yellow band produced by incandescent sodium vapour. To this end, I placed a bit of sodium in a carbon crucible, and volatilized it by a powerful voltaic current. A feeble spectrum overspread the screen, from which I thought the sodium band would stand out with dominant brilliancy. To my surprise, at the very point where I expected this brilliant band to appear, a band of darkness took its place. By humouring the voltaic arc a little, the darkness vanished, and in the end I obtained the bright band which I had sought at the beginning. On reflection the cause was manifest. The first ignition of the sodium was accompanied by the development of a large amount of sodium vapour, which spread outwards and surrounded, as a cool envelope, the core of intensely heated vapour inside. By the cool vapour the rays from the hot were intercepted, but on lengthening the arc the outer vapour in great part was dispersed, and the rays passed to the screen. This relation as to temperature was necessary to the production of the black band; for were the outside vapour as hot as the inside, it would, by its own radiation, make good the light absorbed.

An extremely beautiful experiment of this kind was made in this theatre by Professor Liveing, with rays which, under ordinary circumstances, are entirely invisible. Professor Dewar and Professor Liveing have been long working with conspicuous success at the ultra-violet spectrum, and with Professor Dewar's aid I will now show you this spectrum, as it was shown last week by Professor Liveing. Using prisms and lenses of a certain kind, and a powerful dynamo machine to volatilize our metals, we cast a spectrum upon the screen. You notice the terminal violet of this spectrum. Far beyond that violet, waves are now impinging upon the screen, which have no sensible effect upon the organ of vision; they constitute what we call the ultra-violet spectrum. Professor Stokes has taught us how to render this invisible spectrum visible, and it is by a skilful application of Stokes's discovery that Liveing and Dewar bring the hidden spectrum out with wondrous strength and beauty.

You notice here a small second screen, which can be moved into the ultra-violet region. Felt by the hand, the surface of this screen resembles sandpaper, being covered with powdered uranium glass, a highly fluorescent body. Pushing the moveable screen towards the visible spectrum, at a distance of three or four feet beyond the violet, light begins to appear. On pushing in the screen, the whole ultra-violet spectrum falls upon it, and is rendered visible from beginning to end. The spectrum is not continuous, but composed for the most part of luminous bands derived from the white-hot crucible in which the metals are to be converted into vapour. I beg of you to direct your attention on one of these bands in particular. Here it is, of fair luminous intensity. My object now is to show you the reversal, as it is called, of that band which belongs to the vapour of magnesium, exactly as I showed you a moment ago the reversal of the sodium band. An assistant will throw a bit of magnesium into the crucible, and you are to observe what first takes place. The action is rapid, so that you will have to fix your eyes upon this particular strip of light. On throwing in the magnesium, the luminous band belonging to its vapour is cut away, and you have, for a second or so, a dark band in its place. I repeat the experiment three or four times in succession, with the same unfailing result. Here, as in the case of the sodium, the magnesium surrounded itself for a moment by a cool envelope of its own vapour, which cut off the radiation from within, and thus produced the darkness.

And now let us pass on to an apparently different, but to a really similar result. Here is a feebly luminous flame, which you know to be that of hydrogen, the product of combustion being water vapour. Here is another flame of rich blue colour, which the chemists present know to be the flame of carbonic oxide, the product of combustion being carbonic acid. Let the hydrogen flame radiate through a column of ordinary carbonic acid—the gas proves highly transparent to the radiation. Send the rays from the carbonic oxide flame through the same column of carbonic acid—the gas proves powerfully opaque. Why is this? Simply because the radiant, in the case of the carbonic oxide flame, is hot carbonic acid, the rays from which are quenched by the cold acid exactly as the rays from the intensely heated sodium vapour were quenched a moment ago by the cooler envelope which surrounded it. Bear in mind the case is always one of synchronism. It is because the atoms of the cold acid vibrate with the same frequency as the atoms of the hot, that the pulses sent forth from the latter are absorbed.

Newton, though probably not with our present precision, had formed a conception similar to that of molecules and their constituent atoms. The former he called corpuscles, which, as Sir John Herschel says, he regarded "as divisible groups of atoms of yet more delicate kind." The molecules he thought might be seen if microscopes could be caused to magnify three or four thousand times. But with regard to the atoms, he made the remark already alluded to:—"It seems impossible to see the more secret and nobler works of nature within the corpuscles, by reason of their transparency."

I have now to ask your attention to an illustration intended to show how radiant heat may be made to play to the mind's eye the part of the microscope, in revealing to us something of the more secret and noble works of atomic nature. Chemists are ever on the alert to notice analogies and resemblances in the atomic structures of different bodies. They long ago pointed out that a resemblance exists between that evil-smelling liquid, bisulphide of carbon, and carbonic acid. In the latter substance, we have one atom of carbon united to two of oxygen, while in the former we have one atom of carbon united to two of sulphur. Attempts have been made to push the analogy still further by the discovery of a compound of carbon and sulphur which should be analogous to carbonic oxide, where the proportions, instead of one to two, are one to one, but hitherto, I believe, without success. Let us now see whether a little physical light cannot reveal an analogy between carbonic acid and bisulphide of carbon more occult than any hitherto pointed out. For all ordinary sources of radiant heat the bisulphide, both in the liquid and vaporous form, is the most transparent, or diathermanous, of bodies. It transmits, for example, 90 per cent. of the radiation from our hydrogen flame, 10 per cent. only being absorbed. But when we make the carbonic oxide flame our source of rays, the bisulphide shows itself to be a body of extreme opacity. The transmissive power falls from 90 to about 25 per cent., 75 per cent. of the radiation being absorbed. To the radiation from the carbonic oxide flame the bisulphide behaves like the carbonic acid. In other words, the group of atoms constituting the molecule of the bisulphide vibrate in the same periods as those of the atoms which constitute the molecule of the carbonic acid. And thus we have established a new, subtle, but most certain resemblance between these two substances. The time may come when chemists will make more use than they have hitherto done of radiant heat as an explorer of molecular condition.

The term "theoretical radiation" introduced into the title of this discourse is, I hope, thus justified. The conception of these quivering atoms is a theoretic conception, but it is one which gives us a powerful grasp of the facts, and enables us to realize mentally the mechanism on which radiation and absorption depend. We will turn in a moment to what I have called practical "radiation." It is pretty well known that for a long series of years I conducted an amicable controversy with one of the most eminent experimenters of our time, as regards the action of the earth's atmosphere on solar and terrestrial radiation. My contention was that the great body of our atmosphere—its oxygen and nitrogen—had but little effect upon either the rays of the sun coming to us, or the rays of the earth darting away from us into space, but that mixed with the body of our air there was an attenuated and apparently trivial constituent which exercised a most momentous influence. That body, as many of you know, is aqueous vapour, the amount of which does not exceed 1 per cent. of the whole atmosphere. Minute, however, as its quantity is, the life of our planet depends upon that vapour. Without it, in the first place, the clouds could drop no fatness. In this sense the necessity for its presence is obvious to all. But it acts in another sense as a preserver. Without it as a covering, the earth would soon be reduced to the frigidity of death. Observers were, and are, slow to take in this fact, which nevertheless is a fact, however improbable it may at first sight appear. The action of aqueous vapour upon radiant heat has been established by irrefragable experiments in the laboratory; and these experiments, though not unopposed, have been substantiated by some of the most accomplished meterologists of our day.

I wished much to instruct myself a little by actual observation on this subject, under the open sky, and my first object was, to catch, if possible, states of the weather which would enable me to bring my views to a practical test. Thanks to an individual who devotes her life to taking care of mine, a little iron hut, embracing a single room, has been placed for my benefit, upon the wild moorland of Hind Head. From the plateau on which the hut stands, thre is a free outlook in all directions. Here, amid the heather, I had two stout poles fixed firmly in the ground 8 feet asunder, and a stout cord stretched from one to the other. From the centre of this cord a thermometer is suspended with its bulb 4 feet above the ground. On the ground is placed a pad of cotton wool, and on this cotton wool a second thermometer, the object of the arrangement being to determine the difference of temperature between the two thermometers, which are only 4 feet vertically apart.

Permit me at the outset to deal with the subject in a perfectly elementary way. In comparison with the cold of space, the earth must be regarded as a hot body, sending its rays, should nothing intercept them, across the atmosphere into space. The cotton wool is chosen because it is a powerful, though not the most powerful, radiator. It pours its heat freely into the atmosphere, and by reason of its flocculence, which renders it a non-conductor, it is unable to derive from the earth heat which might atone for its loss. Imagine the cotton wool thus self-chilled. The air in immediate contact with it shares its chill, and the thermometer lying upon it partakes of the refrigeration. In calm weather the chilled air, because of its greater density, remains close to the earth's surface, and in this way we sometimes obtain upon that surface a temperature considerably lower than that of the air a few feet above it. The experiments of Wilson, Six, and Wells have made us familar with this result. On the other hand, the earth's surface during the day receives from the sun more heat than it loses by its own radiation, so that when the sun is active, the temperature of the surface exceeds that of the air.

These points will be best illustrated by describing the course of temperature for a day, beginning at sunrise and ending at 10.20 p.m. on March 4. The observations are recorded in the annexed table, at the head of which is named the place of observation, its elevation above the sea, and the state of the weather. The first column in the table contains the times at which the two thermometers were read. The column under "Air" gives the temperatures of the air, the column under "Wool" gives the temperature of the wool, while the fourth column gives the differences between the two temperatures. It is seen at a glance that from sunrise to 9.20 a.m. the cotton wool is colder than the air; at 9.30 the temperatures are alike. This is the hour of "intersection," which is immediately followed by "inversion." Throughout the day and up to 4 p.m. the wool is warmer than the air. At 4.5 p.m. the temperatures are again alike; while from that point downwards the loss by terrestrial radiation is in excess of the gain derived from all other sources, the refrigeration reaching a maximum at 7.30 p.m., when the difference between the two thermometers amounted to 10° F. When the observations are continued throughout the night, the greater cold of the surface is found to be maintained till sunrise, and for some hours beyond it. Had the air been perfectly still during the observations, the nocturnal chilling of the surface would have been in this case greater; for you can readily understand that even a light wind sweeping over the surface, and mixing the chilled with the warmer air, must seriously interfere with the refrigeration.

Glacial wind from north-east. Stars very bright.

Various circumstances may contribute to lessen, or even abolish, the difference between the two thermometers. Haze, fog, cloud, rain, snow, are all known to be influential. These are visible impediments to the outflow of heat from the earth; but my position for some time has been that a very powerful obstacle to that outflow exists which is entirely invisible. The pure vapour of water, for example, is a gas as invisible as the air itself. It is everywhere diffused through the air; but, unlike the oxygen and nitrogen of the atmosphere, it is not constant in quantity. We have now to examine whether meteorological observations do not clearly indicate its influence on terrestrial radiation.

With a view to this examination, I will choose a series of observations made during the afternoon and evening of a day of extraordinary calmness and serenity. The visible condition of the atmosphere at the time was that which has hitherto been considered most favourable to the outflow of terrestrial heat, and therefore best calculated to establish a large difference between the air and wool thermometers. The 16th of last January was a day of this kind, when the observations recorded in the annexed table was made.

January 16th.—Extremely serene. Air almost a dead calm. Sky without a cloud. Light south-westerly air.

Time.	Air.	Wool.	Difference.

10.	35	28	7
10.30	35	29	6

During these observations there was no visible impediment to terrestial radiation. The sky was extremely pure, the moon was shining; Orion, the Pleiades, Charles's Wain, including the small companion star at the bend of the shaft, the North Star, and numbers of others, were clearly visible. After the last observation, my note-book contains the remark, "Atmosphere exquisitely clear; from zenith to horizon cloudless all round."

A moment's attention bestowed on the column of differences in the foregoing table will repay us. Why should the difference at 6 p.m. be fully 5° less than at 5 p.m.; and again 5° less than at 8 and at 8.30 respectively? There was absolutely nothing in the aspect of the atmosphere to account for the approach of the two thermometers at 6 o'clock—nothing to account for their preceding and subsequent divergence from each other. Anomalies of this kind have been observed by the hundred, but they have never been accounted for, and they did not admit of explanation until it had been proved that the intrusion of a perfectly invisible vapour was competent to check the radiation, while its passing away reopened a doorway into space.

It is well to bear in mind that the difference between the two thermometers on the evening here referred to varied from 4° to 9°, the latter being the maximum.

Such observations might be multiplied, but, with a view to saving space, I will limit the record. On the evening of January 30th, the atmosphere was very serene; there was no moon, but the firmament was powdered with stars. At 7.15 p.m. the difference between the two thermometers was 6°; while at 9.30 p.m. it was 4°, the wool thermometer being in both cases the colder of the two.

On February 3rd observations were made under similar conditions of weather, and with a similar result. At 7.15 p.m. the difference between the thermometers was 6°; while at 8.25 p.m. it was 4°. On both these evenings the sky was cloudless, the stars were bright, while the movement of the air was light, from the south-west.

In all these cases the air passing over the plateau of Hind Head had previously grazed the comparatively warm surface of the Atlantic Ocean, where it had charged itself with aqueous vapour to a degree corresponding to its temperature. Let us contrast its action with that of air coming to Hind Head from a quarter less competent to charge it with aqueous vapour. We were visited by such air on the 10th of last December, when the movement of the wind was light from the north-east, the temperature at the time, moreover, was very low, and hence calculated to lessen the quantity of atmospheric vapour. Snow a foot deep covered the heather. At 8.5 a.m. the two thermometers were taken from the hut, having a common temperature of 35°. The one was rapidly suspended in the air, and the other laid upon the wool. I was not prepared for the result. A single minute's exposure sufficed to establish a difference of 5° between the thermometers; an exposure of five minutes produced a difference of 13°; while after ten minutes exposure the difference was found to be no less than 17°. Here follow some of the observations.

December 10th.—Deep snow; low temperature; sky clear; light north-easterly air.

Time.	Air.	Wool.	Difference.

8.10	29	16	13
8.15	29	12	17
8.20	27	12	15
8.30	26	11	15
8.40	26	10	16
8.45	27	11	16
8.50	29	11	18

During these observations, a dense bank of cloud on the opposite ridge of Blackdown virtually retarded the rising of the sun. It had, however, cleared the bank during the last two observations, and, touching the air thermometer with its warmth, raised its temperature from 26° to 27° and 29° The very large difference of 18° is in part to be ascribed to this raising of the temperature of the air thermometer. I will limit myself to citing one other case of a similar kind. On the evening of the 31st of March, though the surface temperature was far below the dew point, very little dew was deposited. The air was obviously a dry air. The sky was perfectly cloudless, while the barely perceptible movement of the air was from the north-east. At 10 p.m. the temperature of the the air thermometer was 37°, that of the wool thermometer was 20°, a refrigeration of 17° being therefore observed on this occasion.

From the behaviour of a smooth ball when urged in succession over short grass, over a gravel walk, over a boarded floor, and over ice, it has been inferred that, were friction entirely withdrawn, we should have no retardation. In a similar way, under atmospheric conditions visibly the same, we observe that the refrigeration of the earth's surface at night markedly increases with the dryness of the atmosphere: we may infer what would occur if the invisible atmospheric vapour were entirely withdrawn. I am far from saying that the body of the atmosphere exerts no action whatever upon the waves of terrestrial heat; but only that its action is so small that, when due precautions are taken to have the air pure and dry, laboratory experiments fail to reveal any action. Without its vaporous screen, our solid earth would practically be in the presence of stellar space; and with that space, so long as a difference existed between them, the earth would continue to exchange temperatures. The final result of such a process may be surmised. If carried far enough, it would infallibly extinguish the life of our planet.

SOCIETY OF ARTS.

Solid and Liquid Illuminating Agents.*

BY LEOPOLD FIELD, F.C.S.

Lecture III.

Continuing the consideration of those bodies which can be converted into candles without alteration of their chemical nature, we will discuss palm and cocoanut oils; although, like tallow, in an unmanufactured condition, their application is very limited. The family of palms is exceedingly large; and of the number many varieties contribute to the domain of light. I have mentioned the wax palm, which perhaps remits, next to those two which we are now discussing, the largest subsidies to the candle pan; but all other vegetable sources scarcely furnish a tithe of the quantity which is yielded by the *Elais guineenis*, the oil palm, and the *Elais melanococcus*, the cocoanut tree. The former is distributed mainly through the West Coast of Africa, sometimes penetrating pretty far into the interior. Its chief habitat is along the banks of the Senegal and Gambia rivers, which are lined with the rude factories where the natives extract the oil. The fruit of this palm weighs about twenty pounds, and much resembles a large artichoke intersected with small golden plums. Dried specimens can give but little idea of the beauty of this highly oleaginous fruit as it grows on the tree. The berries are separated from the husks, and by boiling in water are divested of their unctuous integuments. The deep golden oil floats on the top, is skimmed off, and put into casks, where it assumes a granular semi-solid condition. There are many varieties of this oil, varying from deep greyish-brown to a lemon-yellow. The best is that known as "Lagos" oil. Originally, before the discoveries of Chevreul and Wilson, palm oil, from its soft nature, was of little use, as by pressing it does not become harder; but a certain kind of candle, which was called the "decimal" candle from the fact of ten going to the pound, was manufactured from the "bagged" palmitin, bleached partially by exposure to air. Messrs. Hempel and Blundell, in 1836, took out a patent for making candles from pressed fats alone. These, however, are little used. Cocoanut candles, or candles from pressed cocoanut, were made, but it cannot be said with any success. Whenever candles from the unmanufactured vegetable oils have been introduced, the glycerine present has proved almost as strong an objection in such cases as in tallow. In 1840, Mr. J. P. Wilson took out a patent for making the original "composite" candle, which was a mixture of the pressed cocoanut oil and stearic acid. These were the result of the demand for cheap self-snuffing candles which arose on the occasion of the Queen's marriage. It is a greasy candle, but comparatively cheap, giving a light of the intense whiteness characteristic of cocoanut oil. Cocoanut oil itself is obtained by pressing the dried and crushed ripe cocoanut. The best brands are sent from Ceylon and Cochin China. The nut is highly oleaginous, and is pressed when all the milk has solidified; a great portion of the oil is extracted, but a large quantity also is sent over in the dried kernel, called *copra*, to be crushed in English mills. It may be

* Cantor Lectures: Reprinted from the *Journal of the Society of Arts*.

well here to mention night lights briefly, although we cannot give much attention to this little illuminator, of universal utility though it be. Night lights, at first called mortars (properly *mortuars*, being burnt by coffins and in dead chambers), are made chiefly of wax, blended with spermaceti, or pure. They have long been used, and their old form, as already observed, was the rush-light. The Romans used a night lamp and shade (*cubiculars*). With the introduction of cheaper materials than wax or spermaceti, their convenient form and elegant light could not fail to introduce a great demand, and by successive improvements in the composition and the cases, the substitution of stearine and pressed cocoanut in the former, and shaving or cardboard in the latter, the night light assumed an appearance to suit the most elegant, at a price within the reach of all. To Messrs. Wilson, of Price's Candle Company, these improvements are mainly due, though, I believe, it was Mr. Field who first encased stearine with cardboard. Messrs. Child's and Clarke's patents (1848-49-57), now adopted by Price's Company, are too well known to need any description, and refer to the special and improved manufacture of the night light and the apparatus for holding it. The amount of night lights consumed annually reaches 50,000,000. The manufacture is simple. The little cardboard case is supplied with a "sustainer," which is a small circular disc of tin with a hole in the centre to hold the wick which is attached to the bottom of the case by a spot of glue. The wicks being thus held upright, the cases are placed in a row and rapidly filled by hand from a kettle containing a mixture of cocoanut oil and palmitic acid; the composition, of course, varies with different makers. So much for the night light, although you would scarcely believe of how much time, labour, and numerous patents this little item has been the subject before it reached perfection.

Passing now to oils actual, and vegetal oils in particular—for I take the palm and cocoanut oils to hold an intermediate position between solid fats and liquid oils—we come to an immense class of seeds, used, some only in their native countries, and many universally, for producing illuminating oils. The chief oil of the old time was olive oil, which now, however, is rapidly being promoted to the rank of an edible, there being nothing special, either in its price or its light, to authorize its furthur supremacy. I have here several specimens of the olive, but this small dark berry, the *Olea Europœa*, is the olive of Italy and the East: the fruit of those silver-grey forests so familiar to all who have travelled along the Riviera and Palestine. The finest oil—what is called virgin oil—is obtained from the berries by gentle crushing; the inferior qualities are the result of harder pressure and ultimate boiling. But little olive oil is now obtained pure, and that which is, is almost entirely devoted to culinary purposes. It is noteworthy that the Italian mill owners themselves find it cheaper to burn petroleum in their lamps, than their own produce. After the invention of Argand, colza oil, from the seeds of the *Brassica Europœa*, was very largely employed, as giving a brilliant light at a small cost, and this vied with sperm oil for a long time; but as olive is now adulterated with colza, so colza, in its turn, was adulterated with rape, and all of them find rivals in continental countries in ground nut, sesame, poppy, and other oils, all of which have characteristics more or less desirable. I have appended a list of the various oils obtained from seeds in all parts of the world, giving, where necessary, such details as may be interesting. But we must regard all these as things of the past, or passing, their places being now taken by petroleum and paraffin; although, till the latter are rendered equally inert, we cannot expect that the virtually safe vegetable oils will ever practically become extinct as illuminants, while their value to the soap-maker increases yearly. It would not be right were I, at this point, to make no mention of cotton seed oil, which year by year assumes a greater position in the oil dominion. It is capable of such a state of perfection that, both in appearance and other properties, under cunning treatment, it can, and no doubt does, pass for olive oil. The gigantic amount of seed thrown off in cotton harvests, and the high percentage of oil contained, renders competition on the part of any other seed abortive. Last year, there were 3,000,000 tons of cotton seed produced, of which only 300,000 tons were worked up, meaning 90,000,000 gallons of oil lost. If I describe briefly the manipulation of cotton seed to extract the oil therefrom, it will serve as a type of the processes applied to most other seeds.

In the old seed crusher the grains were subjected, in bags, to the pressure of wedges, on which "monkeys" fell, as in pile driving. The advantage of such apparatus is its ready manufacture, the only essentials being timber and carpenters' tools. But now more perfect means are adopted, and the following description, which I owe to the kindness of Mr. Felton, secretary of the Cotton Oil and Stearine Company, applies to such.

The seed is first crushed between iron rollers, and is then put under edge-runners (stones), which converts it into a rough meal. It is then heated in a steam jacketed pan, and, when sufficiently warm, is filled into woollen bags, which are put into hydraulic presses, horizontally, and pressed until all the oil is exuded, leaving the cotton cake perfectly hard. The oil, which is quite dark in colour, is then put into a tank, heated with dry steam to about 80° to 85° F., and treated with caustic leys sufficiently to throw down the residuum, consisting of fibrous and gummy matter; the oil, which is of a pale yellow colour, is then drawn off into another tank, and boiled in water, in order to thoroughly cleanse it from all impurities; after this it is filtered, and is then ready for sale. (It is not suitable for distilling.) The residuum or foots is boiled up with open steam, and treated with acid, which, combining with the alkali, leaves a thick black grease. This, when distilled, yields a white stearine, also a hard black pitch.

Passing now from the oils themselves to the vehicles for exhibiting their burning powers, I solicit your attention to the magnificent lamps, which the kindness of the great manufacturers and others has enabled me to place before you. Perhaps no link of importance, from the old bronze lamp of Herculaneum to the exquisite combination of high art and supreme light lent me by Messrs. Williams and Bach, in their Ibis lamp, is omitted. I will, however, not dilate upon beauty or quaintness of form, but content myself with expounding the principles of such as appear to me to constitute an essential link or step forward. The first invention of note must be considered that of Ami Argand, who, in July, 1784, took out a patent, which rendered the lamp practicable as a domestic luminant, and his name indissolubly connected therewith. The principal object of this lamp, to quote his own words, is "to give neither 'smoak' nor smell, and to give considerably more light than any lamp hitherto known." His first structure had simply a chimney* of iron suspended over the flame, which was afterwards exchanged for one of glass. The wick was circular and hollow, thereby admitting of a current of air on both sides the flame. The uprush of heated products of combustion from the top of the chimney, induces an equal ingress of fresh air from below. By discreet adjustment of size and position of the chimney and wick, the supply of air is regulated to exactly impinge on the portion of the flame where the heated vapours come into contact with the atmosphere, and consumes the excessive carbon, which would otherwise appear as smoke. This invention underwent numerous modifications, at the hands both of the originator and others, but the principle remained unaltered. Argand's lamp, after successive improvements, consisted of the following parts:—An annular tube, on which the wick was stretched; a reservoir which contained the oil; a pipe leading from the re-

* The chimney had, however, been suggested previously by Quinquet.

servoir to the wick, and a holder for the glass, which imported, on turning, a spiral motion to the wick, and thereby adjusted the flame. The reservoir was of the kind known as the "bird fountain," whereby a bubble of air entering the small orifice at the base allows the egress of a small quantity of oil. This was first put into practice by Miles in 1781, and has since been applied to a very numerous class of lamps, especially those known as "reading lamps," where the reservoir is higher than the wick. Argand's lamp was suitable for both colza and sperm oils. As the shape was ungainly, many expedients were devised whereby the flame could be fed from a reservoir below. Carcel, in 1798, brought out a lamp which was almost universally used for many years in France. The principle of this was pumping, by two little clockwork pumps, a supply of combustible to the wick. The only objection to this is the constant need of repair to which the delicate mechanism is liable. The supply, when in good order, however, was so extremely steady as to cause this lamp to be taken on the Continent as a standard of illumination. The problem of securing an unvarying supply of oil without such complicated mechanism was one which taxed the ingenuity of many makers. A very favourite means was that of hydrostatic power, whereby a heavier liquid solution was made to raise the lighter oil equably, as it consumed. This idea was evolved from the fertile brain of Hero of Alexandria, 200 B.C. There was also a device for solving the paradox of causing a liquid to rise above its own level, by the flow of a heavy salt solution, into an air-tight chamber, the air being driven into the oil reservoirs above, and forcing out the oil into the lamp. Another ingenious "idea" for trimming the wick by the descent of the oil I do not think would be found to work. Barton, in 1809, invented a very elaborate combination of tubes and chambers, carrying out Hero's idea on an extensive scale, and in connection with an Argand lamp. This appears to have had a considerable popularity, but is now extinct.

Keir, in 1787, made a very ingenious lamp, consisting of two cylinders, the smaller floating in the larger. The wick was attached to the apex of the interior cylinder which contained the oil, and was open at the base, the exterior being filled with salt water. As the oil diminished, the salt water rose in the interior, and sank in the exterior reservoir, while the height of the interior cylinder was adjusted by means of a wooden float. Porter, in 1804, invented a lamp which deserves mention. It consisted of a rectangular box, balanced eccentrically, so that the position—horizontal at the commencement—during burning, gradually approached the vertical. A larger amount of oil being removed from the posterior, caused this to lose weight more rapidly than the anterior, the oil in which was thereby maintained at a level. The name of Smethurst is closely associated with lamps. He was the first to give a slope to the chimney, which Argand had left straight, thus directing the air-current more accurately, and thereby increasing the draught and the brilliancy of the flame. The next invention of importance took place in 1836, when Fanchot invented the moderator lamp as at present used. This had already been foreshadowed in the inventions of Stokes, 1787, Allcock in 1807, and Fayre in 1825, all of whom used pistons which forced the oil up under pressure. Fanchot gave the lamp its present form, which is, briefly, as follows:—The piston fits tightly in the reservoir, being provided with a leather collar, which admits of being raised with ease while the reservoir is full, but the descent is impeded by the collar being pressed against the sides by the liquid. There is, therefore, no outlet for the oil but by a fine tube passing through the piston up to the wick, which is, by this means, fed by a constant stream of oil, the surplus dropping down into the reservoir above the piston. When the piston has fully descended, it is re-elevated by a cog and ratchet apparatus. The flow of liquid up the tube is regulated by a fine piece of wire, which partly closes the same and helps to cleanse it. By these means, very heavy oils can be burnt, and perhaps no lamp has enjoyed greater popularity than this. Its defects are the constant need of winding up, and liability of the fine tube to become clogged. Such are the chief historical forms of the lamp. I will briefly allude to Young's "Vesta" lamp, first used used in 1834, which burnt "camphine," or turpentine, with a very brilliant snow-white flame; and the "Diacon" lamp, which was a modification of the moderator, invented and used in America. This lamp was made the subject of a characteristic novel, published in 1849, wherein a lady searches the world for the best kind of lamp.

The wick has been the subject of numerous modifications. As early as 1773, we find one Leger producing a flat-ribbon wick. Though a great improvement on that of the older cord wick, the flame was too thin, being blown out with every puff of air. Argand introduced the circular wick, which has maintained its form. A great step was made when the flat wick was forced. as in modern lamps, to adjust itself exactly to an annular tube, thus obviating the necessity of pushing the tube into an ill-fitting wick.

In 1865, Messrs. Hincks, of Birmingham, brought out a lamp with the parallel flat flames, called the Duplex, which gives a remarkably good light, and has a world-wide reputation. To the same firm, I believe, are due these ingenious devices for extinguishing and relighting the flame without moving the shade, by merely pressing a trigger.

I ought now to mention, as an entirely different variety, Mr. Holliday's vapour burner lamp, of which the specimen I have here is one of the many thousands to be seen burning on the costermongers' stalls in East and South London. The conical reservoir at the top is filled with light hydrocarbon oil, passing through a tap and tube into a burner of peculiar construction, and being ignited by holding in a flame for a few seconds, will continue to burn without wick furiously and safely as long as the supply is properly regulated. This may be said to be the first lamp which burnt hydrocarbon oils, and no doubt for an open-air flame no better can be, or at any rate has been, devised. About this time invention was very active to devise means of burning hydrocarbon oils with safety, which were being used with more and more frequency in household lamps. In 1866, Leichenstadt invented a lamp for burning a mixture of benzole and camphor, but the dangerous nature of benzole rendered this form undesirable. Aaronson, 1875, by a clever combination of oil and water, constructed a lamp to be extinguished directly it was overturned, or even deflected from the vertical. This masterpiece could also be trimmed, filled, and lighted without moving the shade and chimney. Young and Silber are two names most prominent in the lamp problem. Mr. James Young, as the discoverer and first manufacturer of paraffin oil from shale, was naturally the appropriate inventor of means for its safe combustion, and Young's company now still supply "Vesta" lamps for burning their own productions.

All the inventions thus briefly epitomized have one or other of the following objects in view:—To supply oil regularly to the wick; to apportion the supply of air to the description and quantity of oil to be burnt; to provide simple means for regulating the height of the wick, and consequently, the flame; and finally, to place the burning portion of the lamp in such a position as not to be obscured by the reservoir and other portions. The oldest lamps, as the antique Etruscan, and the cruisie of Scotland, were on the suction principle, and the wick depended for its supply upon its own capillary action. As the level of the oil was constantly varying, so the light varied also, and the first attempts of inventors were directed to maintaining an equal level of oil. The bird-fountain and hydrostatic reservoirs partly attained this end, and the Carcel and Moderator systems were perfect of their class, mechanical or pressure lamps. It is evident that suction lamps depend for their efficacy upon the gravity of the combustible. A spirit lamp, with a good wick, will burn very well, though the wick be several inches above the liquid. Elizabeth Leichtenstadt's patents, 1866, are directed to the burning of camphorated spirit and benzole, in sponge-filled reservoirs; but I am unable to procure specimens or information as to their performance. With liquids volatilizing at such low temperatures, there is always a danger of the formation of explosive mixtures.

In 1834, J. I. Beale, patented a lamp for "the burning of substances not usually burned in such vessels," under which he includes mineral and wood naphthas, and oils from the distillation of coal tar, vegetable tar, and the like; the principle being the vaporization by means of a small secondary flame, from a separate source, which soon burns out, having started the vaporization. This lamp had no wick; the supply of fluid was regulated by forced air.

Parker's lamp, patented 1840, should also be mentioned, as the most successful attempt at heating the oil before combustion. Here the upper part of the chimney was made of copper, and passed through the reservoir filled with a heavy luminant (preferably cocoanut or tallow). The air being extended, the oil fed the wick by its own expansion, regulated by an ingenious mechanism. This was a so-called "sinumbral" lamp, and appears to have been held, by some, superior even to Carcel's as a standard for photometry.

The supply of oil to the wick in all pressure lamps was in excess of the demand, and the surplus fell back into the reservoir. This can only be feasible in the case of heavy oils, especially animal and vegetal. The Russians boast of having constructed a lamp to solve the problem of burning their own heavy hydrocarbon oils, of which Baku produces so vast a quantity; but as the demerits of such oils, especially the clogging of the wick, cannot be ascertained in the few hours their committee appear to have spent upon the investigation, we must defer our meed of applause. The light hydrocarbons, such as petroleum, photogen, solar oil, and their polynomial varieties, must reach the arena of combustion in as small quantities, and at as high a temperature as possible, while the supply of air, both from inside and out, can scarcely be too abundant.

It must be remembered that this lecture has oils rather than lamps for its subject; and, therefore, we must be content with inquiring into the principles underlying the construction of the latter, leaving the mechanical beauties in which these apparatus abound for a more befitting occasion. Since compiling this lecture, also, I have found that Mr. Silber has already embraced its chief points in a masterly paper, read before this Society in 1870 (December 21); in which also, the experiments of Mr. Valentine upon the Silber lamp are adduced. Under the circumstances, therefore, I will content myself with giving a brief description of the Silber lamp.

At first sight the burner appears to be a simple aggregation of concentric tubes—and this, in fact, it is. The use of these, especially of the innermost, bell-mouthed pipes, becomes very apparent in the lighted lamp. From the right hand one of these two lamps, both burning petroleum, with equal wicks and similar chimneys, I remove the interior tube — immediately the flame lengthens and darkens, wavers and smokes. The current of air which is, by this internal conduit, directed into the interior flame surface, is the essential principle of Mr. Silber's invention. The wick is contained in this metal case, surrounded by an air-jacket, which passes down the entire length of the lamp, leaving a small aperture at the base, through which the oil flows from the outer reservoir to the wick chamber. Thus, by the interposition of an atmospheric medium, the bulk of the oil is maintained throughout at a low temperature. Two concentric bell-mouthed tubes pass down the interior of the wick case, and communicate with the air at the base of the lamp, which is perforated for the purpose. Two cones, perforated, the inner and smaller throughout, the largest only at the base, surround the wick, and heat the air in its passage through the holes to the flame. The effect of these appliances is, firstly, by the insulation of the outer reservoir, to avoid all danger of vaporization of the oil, till actually in contact with the wick. As it is drawn nearer and nearer the seat of combustion, the hot metal wick-holder heats, and ultimately vapourizes the luminant, so that at the opening of the wick tube concentrically with the air conduits—all of which are exceedingly hot—a perfect mixture of vapour and hot air is formed, and this it is that is burnt. An all important feature is the shape and position of the chimney which, Mr. Silber asserts, influences the flame to the extent of quadrupling its brilliancy if properly adjusted. The numerical results obtained by the photometry of these lamps, as to brilliancy and price, are truly gratifying. I refrain from quoting disjointed values, and beg to refer you to two tables given in Mr. Silber's paper.

I cannot enter into all the beautiful applications of this principle, with which the Silber Light Company have so kindly and bountifully supplied me. But upon this marine lamp, as it involves certain important modifications, a few moments may be spent with advantage. Its purpose is to maintain an even and steady light, during a violent tempest, with, it may be, waves dashing over it. It is provided with a cut dioptric lens, and a powerful reflector, and the light, which is equal to that of fifty candles, can be seen, on a clear night, for more than five miles. The air enters a chamber, by means of two tubes, about one-third of the height of the chamber itself, perforated. This checks and dissipates the most violent current. After entering, the air expands with the heat, loses much of its velocity, and, being still cooler than the air inside, above the flame, descends to the chamber below the burner. As the heated products ascend, the fresh air is drawn up to the flame to supply their place. The smoke from this paper will best show the direction of the currents. You observe the rapidity with which the smoke rushes into the air-pipe, and enters the chamber, which velocity gradually diminishes in ascending, till it falls over, and descends to the lower chamber, whence it is drawn up and consumed in the flame. I direct a stream of air from this powerful bellows against the inlet, and the flame you see as steady as ever. The products of combustion pass up a conical chimney, and strike against the apex of an inverted cone, which divides the current, and allows the products to pass out on every side. Above the cone is a horizontal plate, projecting on all sides beyond the cylinder it covers, and somewhat convex. This serves to divert any water that may pour upon it, innocuously away. This cover has a space between it and the base of the cone, so that any horizontal air-current striking against the top of the lantern passes through this aperture, meeting less resistance than if it chose the downward direction. As this sweeps away the products of combustion from the top, a gust of wind tends rather to increase the brilliancy of the flame than otherwise.

These lamps have been tested in ships, high towers, express trains, and in every case, successfully. As the carefully-adjusted metal funnel renders a glass chimney dispensable with, there is no part which is liable to damage. The one great point to be observed is keeping the whole case air-tight, except at the legitimate outlets; for, you perceive, when I open the door at the back, be it ever so little, the perfect equilibrium of supply and combustion, hitherto obtaining, is disturbed, and the flame wavers and smokes. With this, we must dismiss the lamps, and with them, the animal and vegetal luminants, from which, the petroleum-burning apparatus, discussed to-night, affords an apt transition to the mineral kingdom.

Table III.—Illuminating Value of the Principal Organic Oils.

Oil.	Duration of combustion under equal conditions.	Mean intensity of combustion 40 gm. 8 h., in single wick lamp.
		Standard burner.
Colza, fine	29	1·04
Colza, trade	11	0·39
Ground nut	35	1·05
Olive	23	1·07
Sperm	29	1·05
Rape	23	0·82
Linseed	14	0·87
Whale	18	0·86
Gingelly	26	0·73
Cocoanut	41	1·06

The best oils for burning, arranged in order according to the above, would be cocoanut, colza, ground nut, olive sperm, whale.

* 35 per cent. cheaper than gas.
† 27 per cent. cheaper than gas.

Note.—It is worthy of remark here that, according to recent experiments of Sir J. Douglas, with lamps brought to their present perfection, colza oil, contrary to what would be expected, gives a superior light to that of the best mineral oil. The cost, of course, cannot be taken into account, paraffin oil costing 9*d.* per gallon against 2*s.* 9*d.*, the average price of colza. But the following table will give a good idea of the relative lights during sixteen hours' trial in Trinity House:—

	Argand Burners. Colza.	Argand Burners. Paraffin.
Maximum intensity of light produced	100·0	85·5
Minimum intensity at end of time (sixteen hours)	81·8	66·9
Percentage of falling off	18·2	21·9
Consumption of oil per lamp in fluid ounces for sixteen hours	42·1	34·0
Relative quantity of light produced per gallon of oil consumed	100·0	103·0

Illuminating Power in Sperm Candles.

	6 wicks.	4 wicks.	2 wicks.	Argand.
Colza oil .	722 cand.	328 cand.	82 cand.	23 cand.
Paraffin oil.	730 „	330 „	80 „	25 „

Equivalent of Sperm to 1 Gallon of Oil.

	6 wicks.	4 wicks.	2 wicks.	Argand.
Colza oil .	26·76 lbs.	28·10 lbs.	25·77 lbs.	28·00 lbs.
Paraffin oil.	24·98 „	26·94 „	27·43 „	28·57 „

NOTE.—A comparative table of the cost of light in various lamps and candles will be given at end of Lecture 6.

List of the Principal Oils employed for Illuminating Purposes.

		Oil.	Acid.
Olea Europœa	Europe	Olive	Oleic.
Linum perenne	Europe	Linseed	(Lin)oleic.
Papaver somniferum	Europe	Poppy	(?) (Lin)oleic.
Cannabis sativa	Europe	Hemp	(Lin)oleic.
Sesamum orientale	Europe	Gingelly	(?)
Amygdalus communis	Europe	Almond	(Lin)oleic.
Guilandina mohringa	Europe	Behen	Benic.
Helianthus perennis	Europe	Sunflower seed	Benic.
Brassica campestris	Europe	Rape	Erucic.
Ricinus communis	Italy, India	Castor	Ricinoleic.
Nicotiana tabacum	Europe, America	Tobacco seed	(?)
Theobroma cacao	South America	Cacao butter	Theobromic.
Cocus nucifera	Ceylon, Cochin	Cocoanut	Rutic, caproic, caprylic, lauric, myristic, palmitic, etc.
Elais melanococcus	West Africa	Palm kernel	(Rutic, caproic, caprylic, lauric, myristic, palmitic, etc.)
		Palm oil	Palmitic.
Arachis hypogœa	Tropics	Ground nut	Hypogeic.
Gossypium Barbadense	America	Cotton seed	Linoleic.
Brassica oleifera	Europe	Colza	Erucic.
Aleurites triloba	Polynesia	Candle nut	(?)
Attalea cohune	Honduras	Cohune nut	(?)
Bassia butyracea	East India	Vegetable butter	Stearic, palmitic, myristic.
Colophyllon calabar	Central America	Calabar	(?)
Garcinia indica	India	Kokum	Palmitic, myristic.
Rhus succedaneum	Japan	Japan wax	Palmitic.
Stillingia sebifera	India	Vegetable butter	Myristic.
Bassia parkii	West Africa	Shea butter	Oleic, stearic.
Myrica sebifera	North America	Myrtle wax	Cerotic.
Ceroxylon andicola	Brazil	Palm wax	Cerotic.
Copernicia cerifera	Brazil	Carnauba wax	Cerotic.

Sp. gr. varying from ·89 to ·92. Average yield about 55 per cent., though some, as the *Aleurites triloba*, yield nearly 85 per cent., and others, as *Linum perenne*, only average 20 per cent.

Reviews.

ANATOMIE DER BAUMENRINDEN. Vergleichende Studien von DR. JOS. MOELLER in Wien. Berlin: Springer. 1882.

(ANATOMY OF BARKS. Comparative Studies by Dr. JOSEPH MOELLER.)

The share of attention paid by authors to barks, as compared with other parts of plants, does not seem to be in relation to the interest they deserve to excite in physiologists and anatomists, to the importance they may claim in respect to pharmacological inquires, or to the variety of tissues and difficulties of diagnosis presented by these organs. It is not long since the minute anatomy of plants has become the object of a more intense study among botanists, and directions have made their appearance in literature for the anatomical investigation of plants, as well as monographical treatises on single species. But there is scarcely a single exclusive publication which undertakes a thorough and systematic treatment of special organs.

The author of this work has undertaken to supply the sensible want of a standard book on the highly interesting section of barks, and has executed his task in a more thorough manner than he could do years ago in his contributions to the comparative anatomy of wood.* Though the book cannot be considered a text-book for the beginner, yet every one familiar with the elements of the anatomy of plants may use it as a guide in his investigations, and the inquirer will find in it at once plenty of clever observations on evolution and the embryology of plants.

* The Royal Academy of Sciences, Vienna, 1876.

The description of the barks of three hundred and ninety-two different species includes the outer, middle and inner strata, the author himself calling attention to the fact that this division neither agrees completely with theory nor exactly to the usual terms. Nevertheless, he has adopted it as the most suitable for the purpose of practical diagnosis. In many cases an epidermoidal layer is added to the three principal strata, which is often interesting by its relation to the "cork-initial."

The peculiarities of structure of each bark are perspicuously put together in the character of the species, and those common to the different species are pointed out in the character of the order, while the results of the inquiry are exhibited again in the conclusive remarks in excellent tables.

The chapter on outer bark contains data on the time, shape, and formation of the "cork-initial" (sc. layer), including the periderma, the bark ("Borke"), and the cork.

The chapter on middle bark contains the data on hypoderma and collenchyma, on the formation and absence of liber fibres, on the appearance and conditions of sclerotic metamorphosis, the shape and presence of oxalate of lime, and the secretory spaces. The chapter on the inner bark, as the most variable and abounding in characteristic elements, treats of the sclerosis of the liber, the occurrence of soft liber, stone cells, or of liber fibres, or both elements at once, the presence or absence, shape and locality. The interesting fact may be mentioned that crystal glands and rhaphides are found without exception in or near to sclerotic cells, which the author accounts for by osmotic influences. Lastly, the sieve-tubes and medullary rays are also described in the chapter on the inner bark.

In spite of the very lucid and thorough treatment of the subject, the author does not want to have his book used as a "clue for determination," since, as he maintains in the introduction, the knowledge of the manifold physiological differences ought to precede the interpretation of the innumerable varieties, which are to be considered as deriving from the first by adaptation. Nevertheless, the book will have its value as a help in diagnosis by the great number of hints and remarks contained in it, assisted by the clearness of description, and the truth of the many plates and engravings.

THE VEGETABLE MATERIA MEDICA OF WESTERN INDIA. By W. DYMOCK. Part I.*

Following in the footsteps of Daniel Hanbury, his late friend and correspondent, Dr. Dymock, has now for some years past been studying the materia medica of Western India, and the work which is now being issued might be styled the Pharmacographia of Western India, inasmuch as it is marked by the same remarkable accuracy of statement and painstaking investigation of doubtful points as that classic work. Nothing has been taken for granted which could be determined by personal observation. In some cases seeds picked out of drugs or obtained with considerable difficulty from a distance have been grown by Dr. Dymock in order to make sure of the botanical origin of a drug; and specimens have been liberally supplied to European chemists to have his own results confirmed, or more completely examined by able chemists with more time at their disposal. Only those who know the difficulty of getting information in the East concerning commercial articles can appreciate the time, trouble and patience required to elucidate a single point in the history or the botanical or geographical source of a drug.

The work before us cannot therefore be judged by an ordinary standard. During the progress of his researches, Dr. Dymock has contributed numerous papers on Indian drugs to the pages of this Journal, and these are now brought together, after having been carefully revised, largely added to by more recent information, and arranged in order according to the natural orders of the plants from which they are derived. The whole work will be complete in four parts. Part I. contains 160 pages, and includes the drugs of the natural orders *Ranunculaceæ* to *Anacardiaceæ*.

Each article is treated in the following sequence:—The botanical name of the plant and the part used; the vernacular names, including Sanscrit, Arabic and Persian; the history and uses; the description of physical characters; of the microscopical structure; and the chemical composition. In the three latter features this work excels all previous works on the materia medica of India, and there can be but little doubt that it must remain for many years the standard work on the subject. The author's object, as stated in the preface, has been to give a short summary of the history and uses, to describe each article with sufficient minuteness to insure the detection of any adulteration, and to draw up a condensed account of what has been already published concerning the chemical composition of the different drugs. The author, however, has done more than this, as he has given under each article references to the best papers or works on the respective drugs. It is difficult to judge fairly of the whole volume from the first part, since a number of drugs, the botanical source of which could not be settled, will be placed in a separate list, and the complete work will doubtless possess advantages that cannot appear in the commencement.

The author modestly deprecates imperfections and asks for suggestions, inquiries and further information. We may venture to remark, therefore, that a good index of vernacular names and references, where possible, to a published figure of the drug, would add much to the value of the work as a book of reference for merchants at home and abroad. We cordially hope that the learned author may meet with the co-operation he desires and that his work may prove as successful as he could wish in bringing into notice valuable remedies and in causing to sink into oblivion those which have no real value.

THE DENTAL MATERIA MEDICA AND PHARMACOPŒIA. By J. STOCKEN, L.D.S. Eng., assisted by THOMAS GADDES, L.D.S. Eng. and Edinb. Third Edition.*

The disappearance of the first edition of this now well-known work in four months after it was issued, and the absorption of a second edition sooner than was expected, may be taken as evidence of the appreciation with which this Dental Pharmacopœia is regarded by the members of that profession. It needs only to turn over its pages to see that the work is kept well up to date and that no new remedies or preparations are omitted that have been proved worthy of acceptance during the last few years; presenting in this respect a remarkable contrast to the British Pharmacopœia. Thus we find in it menthol, thymol, oil of eucalyptus, salicylic acid, resorcin, hamamelis, jaborandi, gelsemium, ethyl bromide, ethidene dichloride, calcium sulphide and numerous other remedial agents of recent introduction into medicine. The increase in bulk of the book by nearly one hundred pages is due almost entirely to additions of this kind and to new formulæ, only sixteen pages being devoted in part to additional notes in the elementary portion of the work and in part to an index of diseases with the remedies appropriate to each. This index is a new feature in the Pharmacopœia and will doubtless be found extremely useful as giving the dentist at one glance the power of selecting from a number the agent most appropriate to the case in hand.

The great value of the Dental Pharmacopœia seems to reside in the large amount of practical information derived from personal experience, which is found on almost every page. Thus, in using carmine for colouring tooth powder it is explained how by the method of treatment recommended the colouring power of the carmine is nearly doubled, and under tincture of gelsemium it is stated that "the tincture contains only a trace of tannin and may be given with any of the preparations of iron." In the portion devoted to special pharmacology, and which occupies nearly half the work, not only are the characters of each drug given, but the mode of preparation and the physiological effects and therapeutics. It thus becomes a pharmacopœia combined with the advantages of a work on materia medica, a commentary on the Pharmacopœia and treatises on physiology and therapeutics. It is no wonder, therefore, that it is valued in dental practice. Although only one-fifth larger than the last edition it is twice the thickness, being printed on stouter paper, which renders the type clearer and easier to read. In addition to this the headings of the subjects have been printed in heavier type, so that the present edition is more convenient for reference and for reading. The typographical errors are remarkably few, and the work throughout bears evidence of careful revision. There can be but little doubt that the present edition will be found as acceptable as its predecessors. It is not without satisfaction that we notice on the title page, "Pereira Prizeman for Materia Medica" (Mr. Stocken having gained the prize of the Pharmaceutical Society in 1850 for materia medica), since it bears witness that there are members of the Society who are quite as capable of producing an excellent Pharmacopœia as their medical brethren.

COMMENTAR ZUR PHARMACOPŒA GERMANICA EDITIO ALTERA. Edited by Dr. HERMAN HAGER. Second Edition. Parts I. to V.*

No reader who is accustomed to resort to the pharmaceutical literature of Germany will require to be reminded as to the valuable nature of the work of which the commencement of a new edition is now before us. For the sake of those who are not, we may say that it is unlike any work with which we are acquainted in the English language, for although it is nominally only a commentary on the Second Edition of the German Pharmacopœia, it really constitutes a cyclopædia of information upon most of the subjects in which pharmacists are particularly interested. The order of the arrangement is alphabetical, following the Latin nomenclature adopted in the German Pharmacopœia, and some idea of the exhaustive treatment of the principal subjects may be best conveyed by an analysis of the first article in the book, on "Acetum," which occupies eighteen pages. It commences with the Latin, German, French and English synonyms, followed by a translation of the Latin official description, and a historical notice. Then come the methods of manufacture, including, besides the old plan of spontaneous fermentation, the "Orleans" method introduced by Pasteur and the chemical method of direct oxidation. The theory as to the formation of acetic acid is explained, illustrated by chemical formulæ, and there are figures of the vinegar eel, the vinegar bacterium and the *Mycoderma Aceti*. The different kinds of commercial vinegar are mentioned, as well as the characters by which they can be distinguished, and several pages are devoted to the examination of vinegar for impurities and adulterations. In the five parts before us, among other subjects, all the medicinal acids are treated of in a similarly thorough manner, and, where required, ample tables, showing the relation between the specific gravity and the strength of the solution, are given. The articles on the botanical materia medica are freely illustrated, some of the microscopical drawings being very good, while the comments on the different preparations are evidently the outcome of a wide practical experience, and convey many valuable hints. The fifth part only reaches to "Benzinum Petrolei," so that the whole work promises to make at least three bulky volumes.

KOMMENTAR ZUR ZWEITEN AUFLAGE DER PHARMACOPŒA GERMANICA. Nebst Ubersetzung des Textes sowie einer Anleitung zur Massanalyse. Zum praktischen Gebrauche bearbeitet von O. SCHLICKUM, Apotheker.† 1883.

This volume has for its principal objects to provide German pharmacists who may find difficulty in reading the official Latin version of their national Pharmacopœia with a translation of it into their own language, to add in the shape of a commentary such remarks as may appear desirable for the elucidation of the text, and to furnish an introduction to the practice of quantitative analysis, which has assumed additional importance in consequence of the greater prominence given to it in the new edition of the Pharmacopœa Germanica. That there is room for such a work there can be no doubt. Putting on one side the fact that in the translation into Latin of the original manuscript as settled by the Pharmacopœia Committee in German, several obscurities, if not mistakes, have crept in, it will be convenient to have an edition in the vernacular for the every day work of the laboratory. Then, as has been before remarked in this Journal, the official descriptions are kept within very narrow limits, synonyms, formulæ and processes, except when absolutely necessary, being excluded. In the work before us, not only are these supplied by the author, but the commentary contains a considerable amount of practical information under the different titles. An attempt has been made to illustrate the work, not, however, with uniform success; some of the engravings might pass muster, especially a number that appear to be copies, if not *clichés*, of engravings in Bentham's 'Handbook of the British Flora,' but a few of them are beneath criticism. For those British pharmacists, however, who have the wisdom to give a place on their bookshelves to information concerning the practice of pharmacy in other countries than their own Mr. Schlickum's work can be recommended as a convenient and trustworthy representative of the German Pharmacopœia.

Correspondence.

GALIUM APARINE.

Sir,—Noticing that in "The Month" mention has again been made of the plant *Galium Aparine*, I have thought that perhaps the following extract from Robinson's 'Family Herbal,' a book largely used by herbalists and certainly one of the best of its class, may be interesting to many of your readers.

After giving a description of the plant, time of flowering, etc., and also the synonyms by which it is known, such as "Cleavers," "Clevers," "Gooseshare," or "Goosegrass," it goes on to say:—"The juice of the herb is a good styptic for bleeding wounds. It is taken in broth to keep those lean who are apt to grow fat. The distilled water drank twice a day is good for the yellow jaundice and the decoction also has the same effect and stayeth lasks, both are useful in the bloody flux. The juice is also very good to close up the lips of green wounds and the powder of the dried herb cures old ulcers. Boiled in hog's lard it relieves hard swellings and kernels in the throat. The juice is good for earache. It is a renowned diuretic, most appropriate to remove speedy suppression of urine, gravelly complaints, removing slimy matters and obstructions from the kidneys and bladder. It has been found useful in the cure of scurvy. The infusion should always be made in cold water, say 4 ozs. to 2 pints."

If the above be true, notwithstanding the almost antagonistic modes in which it is to be presented, one would say it is the plant from which the elixir vitæ ought to have been made.

That it is a useful herb the writer can testify, he having seen the benefit of its use in the form of an ointment combined with yarrow (*Achillea Millefolium*) for cuts, bruises, and sores of different kinds.

It also forms one of the principal components of a "herbal beer" made in some parts of the country by the cottagers, who seem well aware of its many qualities, and who sometimes eat it in the form of a salad.

Dr. Quinlan is doing good service in endeavouring to find out and bring before the medical profession the properties of one of the commonest, and, for that reason, probably still much neglected plants, which possibly may be proved to be one of the most useful herbs this country possesses.

GEO. SPENCER.

Associate.—All communications respecting the addressing of the Journals should be sent to the Secretary.

Inquirer.—The preparation is now official in the Pharmacopœa Germanica.

J. Barth.—Babington's 'Manual' or Bentham's 'Handbook of British Plants.'

Westward.—In many of the States the practice of pharmacy is now regulated by legal enactments, but the provisions are not at all uniform throughout the Union.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Wright, Dott, Fennell, Kittow, Greshoff, Mabeu, Cormack, Morgan, Pollard, Brown, Wellcome, Radley, Attfield, Augier, Haywood, Wetzel, Frazer, Jones, Atkins, Careless, Junior, Farr, Inquirer, Glasgow, Minor, Nonplus, Inquirer, Jumbo, Victim, G. H. J. J., V. S.

"THE MONTH."

August and September are pre-eminently the holiday months of the year amongst the dwellers in cities, the time when everyone that can leaves the hurlyburly and stifling atmosphere of crowded streets for the neighbourhood of the yellow sands, the breezy downs, or the flower-spangled lanes and commons of the country. Doubly precious is such a change to the man whose hobby lies in the direction of the study of nature; to whom the relaxation does not mean the distressing *ennui* of nothing to do, but an opportunity for clothing with life and grace the dry bones of science with which he has been obliged to content himself whilst studying it shut up among the busy haunts of men. For instance, there are no doubt botanists and entomologists who having made themselves familiar at home with the writings of Darwin, Lubbock, and others on the fertilization of flowers by insects, will this season while away many a pleasant hour in following up in the country the observations on the constancy of insects in their visits to flowers which were a short time ago laid before the Linnean Society by Mr. A. W. Bennett and Mr. R. M. Christy (*Journal*, August 14). Although the subject has special interest just now when everything connected with the fertilization of flowers by insects is being so fully discussed, it is by no means a new one, Aristotle having made the assertion that "during each flight the bee does not settle upon flowers of different kinds, but flies, as it were, from violet to violet, and touches no other species until it reaches the hive." The two gentlemen named did not, however, confine their observations to the bee family, but extended them to various species of Lepidoptera and Diptera, and have placed on record a large number of interesting details, for which reference must be made to the original papers. With respect to butterflies, Mr. Bennett thinks that on the whole they manifest but a small degree of constancy in visiting flowers; though the great majority of those on which they were seen to settle were either yellow or pink, and after settling on one of these colours they seemed to show a marked tendency to adhere to it. Two species of Syrphidæ, or "hover-flies," also showed little constancy, though this may be accounted for by the fact that they are rather consumers than conveyers of pollen. But the Apidæ exhibited much greater constancy. Thirty-three observations were made of different species of *Bombus*, or "humble bee." In four instances the bee visited the flowers of three distinct species, irrespective of colour; in six instances the flowers of two species were visited, the colour being nearly the same; and in twenty-three instances the bee confined itself to a single species, though the plants chosen by the different bees were of the most various kinds and colours, some shade of pink, however, largely predominating. There could be no doubt as to this constancy being intentional, the bee frequently traversing a considerable distance without alighting, so as not to mix its pollen. But it would appear that colour is not the sole guide, since both Mr. Bennett and Mr. Christy observed that the same bees would visit indifferently white and purple foxgloves, whilst passing by flowers of any other species. The common hive bee was observed six times, and only on one occasion was it seen to visit the flowers of more than one species, and then it made one visit to the blue *Scabiosa succisa*, followed by nine in succession to the pink *Centaurea Scabiosa*. Another bee paid twenty-four consecutive visits to the flowers of *Serratula tinctoria*, obviously rejecting those of *Centaurea nigra*, which are not unlike them in general appearance and are nearly of the same colour. It is an interesting circumstance, to which Mr. Bennett calls attention, that the constancy of the insect appears to be in proportion to the part performed by it in carrying pollen from flower to flower. Mr. Christy's observations are quite confirmatory of Mr. Bennett's. He considers the hive bee to be perfectly methodic in its habits, at any rate whilst there is a fair supply of flowers, though when these are scarce it may not be quite so scrupulous; he also thinks that the humble bees show a fairly high degree of constancy. The Lepidoptera observed by him were not so numerous as those watched by Mr. Bennett, but seemed to exhibit more constancy.

At least two different natural productions met with in Australia pass under the name of "manna" among the colonists. One of these occurs originally as a moderately viscid liquid under thin pieces of exfoliating bark on different species of eucalypts, from which it falls in drops in a more or less solid state to the ground. This kind, which consists of mellitose, has been looked upon as being produced by a species of *Cicada*; but according to Mr. Tepper (*Journ. Linn. Soc.*, xvii., 109) that is not the case, the liquid ejected by the cicada not being sweet. The real producer of this "manna" is a small larva, probably of a species of *Psylla* or allied genus, which is found under a white "fluffy" substance that always surrounds and frequently overspreads the clear liquid on the bark. The other kind is a solid manna that forms around the branches or on the leaves of eucalypts, as *Eucalyptus oleata* and *E. odorata*, in white scales, and is the product of the "lerp" insect. It consists of roundish discs of about a line in diameter, formed of small irregular agglutinated globules of solid mellitose. These occur most plentifully around the branchlets springing from the stumps of trees that have been partially destroyed by fire, extending frequently for five or six inches. The discs appear first as small specks in December or January, and under each may be found a small larva, fixed to the spot by its short proboscis which is buried in the bark.

An investigation, carried out on behalf of the Secretary of State for India by Messrs. McDougall Brothers, relative to the quality of Indian wheat, forms the subject of a very interesting parliamentary paper that has just been issued. Four kinds of Indian wheat, "fine soft white," "superior soft red," "average hard white," and "average hard red" were submitted to a comparison with eleven other kinds from various sources as to the quantity and quality of flour each yielded and the character of the bread that could be manufactured from it. Messrs. McDougall pronounce the four Indian varieties to be exceedingly useful wheats; in fact hardly equalled by any other kind for what is deficient and wanting in the English market. They did not prove to be rich in gluten,—indeed, the first-mentioned yielded a very small proportion,—but their extreme dryness will, it is considered, render them invaluable for admixture with English wheats that may be out of condition through moisture; further, the thinness of the skin and consequent greatness of the yield of flour, which is almost unprecedented, place them in the front rank as a "miller's wheat," whilst the flour itself yielded a larger proportion of bread than that from any other wheat examined. But, unfortunately, the Indian wheats are marked by a distinct beany, almost aromatic flavour, in addition to which the flour is "ricey" and yields a bread too close in texture and with a hard and brittle crust; they are not therefore likely to come into use in this country without a liberal admixture of other wheats. It is probable, however, that they might be employed in the proportion of 25 to 50 per cent. together with home-grown or other wheats, such as American, possessing a fine sweet, milky, or nutty flavour, and to this extent they promise to both miller and baker a larger margin of profit than any other kind.

The apparently contradictory statements made respecting the fermentation which takes place during the operation of bread-making, to which reference was made recently in these columns (see before, p. 64), have provoked further discussion. It will be remembered that whilst M. Chicandard alleged that the fermentation was not alcoholic, but entirely due to the physiological action of bacteria, M. Mousette recorded that he had recovered a considerable quantity of alcohol from liquid obtained from the condensation of vapour escaping from an oven during the baking of bread. A communication from M. Boutroux (*Comptes Rendus*, xcvii., 116), appears to reconcile these two statements. He says that upon examining a sample of leaven, such as was used in the making of bread in a locality remote from any brewery, where it was preserved by successive cultivations in the paste of rye bread, he recognized the presence of numerous bacteria and of four other distinct kinds of microscopic organisms, which, when separated by cultivation in appropriate mediums, proved to be *Mycoderma vini*, two true yeasts, and an organism resembling a species of *Saccharomyces*, but devoid of any fermentative power. M. Boutroux is of opinion that the bacteria are the most active agents, though he thinks that the preservation of two species of yeast in a leaven far from any brewery renders it difficult to deny to them an accessory *rôle*; whilst, therefore, not hesitating to regard the "peptonic" fermentation as the most important, he considers that alcoholic fermentation is not excluded.

An editorial statement is made in *New Remedies* (August, p. 225) as having some practical interest in relation to the value of the gastric secretion of the pig taken at different times, which may be safely classed among "things not generally known." It is said that a well-known manufacturer of pepsine,—taking advantage of the fact that the contemplation of appetizing food not only causes an increased flow of saliva, but also stimulates the secretion of gastric juice,—before killing his pigs turns them fasting into a pen where a trough filled with hot mush is covered with a wire screen to prevent them from eating and thus absorbing the pepsine contained in the peptic glands. The yield of pepsine from the stomachs of pigs killed soon after being subjected to this preliminary treatment is said to exceed that obtained when it is not adopted.

In a report on the Trade and Commerce of Smyrna, Mr. Consul Dennis states that the export of liquorice root is largely increasing. The plant grows wild throughout vast districts in the interior and the only cost is for the labour of digging it up, drying and packing it and transport to the coast for shipment. The roots are packed by hydraulic pressure in bales, weighing each from 280 to 340 lbs., and of these 63,000, valued at £127,600 were exported in 1881. The entire export, with the exception of a small quantity sent to France and an insignificant one to this country, goes to the United States where it is boiled down and converted into paste. Some paste is also manufactured in the Meander and Hermus valleys, the roots being allowed to dry through the summer, during which they lose 60 per cent. by weight; they are then ground, the powder boiled with water and the liquor poured into boxes to cool. The Turkish liquorice paste is in mass, as it will not retain the stick form without the addition of some extraneous ingredient; neither is it so sweet as that of Spain or Sicily, but on the other hand it is said to keep better.

Writing to the President of the Academy of Sciences, from Buenos Ayres (*Comptes Rendus*, xcvii., 206), M. Sacc expresses his gratification at the extent to which during the last ten years the cultivation of the best species of cinchona has been carried on in Bolivia. In the mountains, he says, they are now sown by thousands in nurseries and afterwards transplanted, and he gives a list of seven villages which possess nearly four million cinchona plants between them. The trees are full grown in ten or twelve years and then yield 6 to 8 per cent. of bark, the unscientific method of cutting them down prior to the removal of the bark being at present adopted. The Bolivian calisaya bark from this source is said to yield equal to 3 per cent. of quinine sulphate.

According to a communication to the *Adelaide Observer* an experiment in cinchona cultivation that is being carried on in a plantation in the "Northern Territory" of South Australia is progressing very favourably. The "succirubra" plant is the kind most numerously grown, though some good results have been obtained with the "officinalis."

Some further information has appeared (*Comptes Rendus*, xcvii., 174) concerning the new alkaloid, cinchonamine, isolated by M. Arnaud from a "cuprea" bark (*Pharm. Journ.*, [3], xii., 626) which he now states to have been derived from *Remijia Purdiana*. He states that he has again obtained the alkaloid in a state of purity from fresh samples of bark and that several of its salts have been prepared. He finds that it combines readily with acids, the salts formed being usually well crystallized and only slightly soluble in water, especially in the presence of an excess of acid; in hot alcohol they dissolve freely and upon cooling of the solvent crystallize out more readily than from an aqueous solution. The hydrochlorate crystallizes in two forms: from an acid liquid as an anhydrous salt, in very brilliant exceedingly thin prismatic laminæ, very slightly soluble in acidulated water, not efflorescing even at 100° C.; and these when redissolved in hot pure water recrystallize upon cooling in thick flat dull and opaque prisms, much more soluble than the original crystals in both hot and cold water, efflorescent, and containing a molecule of water of crystallization. This property possessed by the anhydrous hydrochlorate of crystallizing in acidulated water allows of the easy separation of cinchonamine from other alkaloids accompanying it in the bark of *R. Purdiana*. The observation has been made by Dr. Laborde that cinchonamine is exceedingly toxic, even in very small doses.

The *Journal de Pharmacie et de Chimie* quotes a report from the French Consul-General at Calcutta, recently communicated by the French Minister of Agriculture and Commerce to the Comité Consultatif d'Hygiène de France, in which the cinchona febrifuge prepared in India under Government auspices from the bark of *Cinchona succirubra* is spoken of in not very favourable terms. It states that analysis has shown that quinine is present in the mixture only in small proportion, about 12 to 13 per cent. of the whole, and expresses an opinion that in spite of the difference in price of this product and that of quinine the latter will continue to hold the exclusive confidence of medical men.

A further contribution to existing evidence as to the unsatisfactory nature of the pharmaceutical preparations of cinchona has been made by M. Tanret (*L'Union Pharm.*, xxiv., 352), who has examined for alkaloidal strength, astringency and acidity a number of samples of soft extracts of cinchona prepared by himself from different kinds of bark such as are now met with in commerce, as well as other samples from the principal manufacturers of pharmaceutical products in Paris. The cinchona tannin principle was estimated in equivalents of tannin from nut-galls and the acidity in terms of acetic acid. M. Tanret found that some of the extracts, such as those prepared from Loxa bark, contained but little alkaloid and much tannin; those from Huanuco bark, on the contrary, contained five or six times more alkaloid and only one-third as much tannin. Two others, from "grey" barks not more distinctly defined, contained no more alkaloid than the Loxa bark preparations and only one-third as much tannin; whilst some preparations from "Indian barks" appeared to contain little tannin, but sometimes very notable quantities of alkaloids. The conclusion to which M. Tanret arrives is that the medical man cannot know exactly what he is ordering for his patient when he prescribes the soft extract of cinchona.

A short time ago a paper by Mr. Rother was printed in this Journal (April 21, p. 860) describing a process for the preparation of a "tinctura opii deodorata," in which the novel feature is the use of a mixture of vaselin and spermaceti for the removal of the odorous principles. Mr. G. W. Sloan has been engaged in the pertinent inquiry as to how far the product compares in alkaloidal strength with that obtained by the official process and reports (*Am. Journ. Pharm.*, lv., 392) that when using an opium containing 13·80 per cent. of morphine he obtained a "deodorized" tincture representing only 7·10 per cent. of the alkaloid. Unfortunately the fatty substances were thrown away before they had been examined for the missing morphine.

It is evident that the prolonged boiling to which hops are submitted in the ordinary operations of brewing, whilst it is favourable to the solution of extractive matter, is destructive to the volatile aromatic principles. To overcome this disadvantage M. Boulé, a pharmacist of Bourges, has patented a process (*L'Union Pharm.*, xxiv., 373) by which the lupulin is first removed by rubbing the dried hops upon suitable sieves; the strobiles are then exhausted with water, the liquor evaporated to dryness, and the extract powdered and mixed with the lupulin. The product is kept in hermetically closed vessels until required, when it is added in definite quantities to the liquor in the vat five minutes before the cessation of the boiling. The extractive dissolves immediately, but the lupulin is said to remain in contact with the liquid during the whole period of fermentation, yielding a more aromatic beer which keeps for a longer time.

A communication from M. Henriot was recently read before the Academy of Sciences (*Comptes Rendus*, xcvii., 218) upon the alleged conversion of brucine into strychnine by Professor Sonnenschein, whose experience, however, he says, he has been unable to repeat. That the supposed conversion was based upon a mistake has been long ago demonstrated, and the communication is only mentioned here as illustrating the desirability that intending investigators should make themselves acquainted with the literature of a subject before working upon it, for probably had M. Henriot been acquainted with the exposure of Sonnenschein's mistake by Mr. Cownley, confirmed by Mr. Shenstone (*Pharm. Journ.*, [3], vi., 841, and vii., 652), he would not have set himself the unnecessary task of a third time killing the slain.

A short time since the Pharmacie Centrale de France received from its Rhodes correspondent a quantity of the substance described by Guibourt under the name of "écorce de storax" or "storax rouge de commerce." It consisted of compact cakes entirely composed of pieces of thin bark, with some corky *débris*, agglomerated by strong pressure, and was represented to be a residue from the preparation of liquid storax. The colour was a dark wine-red with a slight whitish efflorescence, and the odour was strong, balsamic, analogous to that of peru balsam, and very slightly bituminous. The cakes appeared to be still rich in resinous and aromatic constituents, and M. Ferrand reports (*L'Union Pharm.*, xxiv., 349) that when treated with solvents the substance yielded to alcohol 17·66 per cent. of extract, to ether 16·61 per cent., and to carbon bisulphide 10·76 per cent. These extracts appeared to contain a true balsam having some of the properties of storax, and capable of being utilized in perfumery if not in medicine. The raw material is said to be obtainable at a low price, there being little use for it at present.

In the estimation of tannin by the gelatine process a difficulty arises through the persistence with which the precipitate produced remains diffused through the liquid, rendering it difficult to determine the exact point at which the addition of the standard gelatine solution should cease. According to M. Rouquès (*L'Union Pharm.*, xxiv., 359) this may be overcome by first adding to the astringent liquid some precipitated barium sulphate and stirring the mixture briskly with a glass rod while pouring in the gelatine solution; the barium sulphate becomes thus entangled in the gelatinous precipitate and by virtue of its weight carries it rapidly to the bottom.

At a recent meeting of the Massachusetts State Pharmaceutical Association, Mr. Flynn mentioned (*Proceedings*, 1883, p. 103) that the red colour sometimes assumed by carbolic acid is precipitated upon treatment of a solution of the acid with a solution of chloride of sodium. Professor Markoe confirmed the statement, and said that a 5 per cent. solution of salt was sufficiently strong for the purpose; but he also pointed out that, as a rule, the pharmacist would not be justified in adding sodium chloride to his carbolic acid.

In most of the published processes for the estimation of salicylic acid in liquids the use of ether has been recommended to dissolve out the acid. M. Malenfant advocates (*Journ. Pharm. et de Chim.*, [5], viii., 106) the substitution of chloroform for ether, as dissolving the salicylic acid equally well and being more manageable. He proceeds by shaking together moderately in a flask 50 c.c. of the wine or other liquid to be examined and 20 c.c. of pure chloroform, in such a way as to avoid complete emulsion taking place. The mixture is then thrown on a funnel having a robinet and allowed to stand a few minutes, when it separates into two layers. About 10 c.c. of the chloroform layer is then drawn off into a test tube, and a drop of tincture of perchloride of iron in solution in several cubic centimetres of distilled water added. If any salicylic acid were contained in the liquid submitted to analysis, upon shaking this mixture and letting it stand the water which will float above the chloroform will show the characteristic violet colour. If a quantitative analysis be required the usual colorimetric method may be adopted.

Herr Beckurts has described (*Pharm. Centralh.*, xxiv., 377) the results of an examination of a spurious oil of cloves, which was reputed to be of English origin. It was yellowish in colour, had only a weak aromatic taste, and differed but little in odour from true oil of cloves. The sp. gr. was 1·03, instead of 1·041 to 1·060, as required by the German Pharmacopœia; when exposed to bromine vapour it assumed neither a blue nor a violet colour, but became black; a drop of the oil dissolved in four grams of alcohol was not coloured blue, but green, upon the addition of a drop of dilute solution of perchloride of iron; and water after being shaken with the oil showed an acid reaction. When submitted to distillation, 9 per cent. passed over at 82° C., and proved to consist of a compound ether—formate of propyl; the other constituents were recognized to be some genuine oil of cloves and a much larger quantity of a compound apparently belonging to the phenols.

Bitumen Judaicum, or asphalte from the Dead Sea, is one of the numerous substances that have been put forward in France as a means of combating the phylloxera. According to some information furnished to the French Academy (*Comptes Rendus*, xcvii., 492), the Arab writers, in speaking of the use of this pitch as an insecticide, distinguish three kinds: first, the kind thrown up by the Dead Sea from time to time, which is solid and appears to be identical with the commercial substance; second, that which is found on the surface of the soil in the neighbourhood of the Dead Sea, which is also solid, and that which is obtained in the same locality from below the surface, which is liquid. A sample of the first kind having been examined by M. Delachanal, he found it to yield products of distillation analogous to those obtained from petroleum, together with more than 3 per cent. of sulphur. As the substance upon incineration only gave 0·273 per cent. of ash, the sulphur, or at any rate, the greater part of it, could not have been present as metallic sulphate The presence of so much sulphur would appear to point to a mineral origin for this bitumen; and to separate it from those which are entirely of organic origin.

Herr Heumann has made the interesting observation that under certain conditions sulphur is capable of exhibiting a phosphorescence equal to that of phosphorus (*Berichte*, xvi., 139). When, for instance, it is heated in a dark place upon a metal or porcelain plate the vapour omitted is brilliantly phosphorescent. Sulphur then appears to burn with a clear, scarcely bluish flame very different from the blue flame of its combustion at a high temperature, whilst instead of the odour of sulphurous acid the vapour resembles in smell a combination of sulphuretted hydrogen, camphor and oxygen. If, too, a heated glass rod be plunged into powdered sulphur, and the blue flame resulting from the ignition of the adherent particles be extinguished, as long as the glass is hot a vapour will continue to be emitted, which in a dark place takes the appearance of a distinctly visible pale flame. Certain compounds of sulphur also, such as cinnabar and the sulphides of antimony, arsenic and tin, hyposulphite of soda and xanthate of potash, show when heated in obscurity a pale phosphorescence and emit vapours that have not the odour of sulphurous acid gas. The phosphorescence of sulphur is accompanied by a slight evolution of heat, but not sufficient to char paper.

From the nineteenth annual report of the Chief Inspector under the Alkali, etc., Works Regulation Act, it would appear that the treatment of the waste heaps from alkali works is still a very difficult subject. When no direct operation is carried out for the recovery of the sulphur the alkali makers attempt by beating down the waste firmly as it is laid and making a hard smooth surface to exclude the air and thus prevent decomposition. In this, however, as is known, they are only partly successful; the rain falling upon the heaps is absorbed and carries with it oxygen where the atmosphere unaided could not penetrate, the result being that decomposition goes on and an offensive yellow drainage is set up. Some idea of the enormous quantity of sulphur continually being thus wasted may be formed from the fact that in the course of some experiments in connection with the drainage from one ground it was ascertained that something like twelve tons of sulphur, worth at least £70, was being carried away daily by the various drains of yellow liquid. As a temporary expedient, Dr. Angus Smith suggests the digging of pits for the reception of alkali waste drainage, from which it could be pumped for treatment at some central station.

PREPARATIONS OF PEPSIN.*

BY DR. ADOLPH TSHEPPE.

Although an immense amount has been written and published on this subject, during the last decade, our knowledge and our individual judgment regarding the same has by no means made much advance, and to-day we are still in the same position of empirical experimentation in which we were formerly. We admit having made a decided progress, but if we consider the great popularity enjoyed, for instance, by preparations of pepsin, proven by experimental research to be worthless, the practical application of what is known concerning the use of this remedy seems to have been promulgated only to a very limited degree, especially in the medical profession. The following remarks have been written with a view to furnish answers to questions frequently asked me.

* Lecture delivered April 12 before the New York Deutsche Apotheker-Verein, translated by Hugo Engel, M.D. (The translation in part revised by ED. N. R.). Reprinted from *New Remedies*, August, 1883.

The gastric juice, *vulgo* pepsin, was introduced as a remedy by Dr. L. Corvisart, who supposed that this juice, which was recognized also as the digestive principle for albuminoid bodies outside of the stomach, would be indicated in all cases in which, from failure of its secretion, disturbances of digestion or dyspepsia existed. The physiological supposition has been verified by experience, and the gastric juice has since been employed in different forms, as wine, elixir, glycerol, or in the dried state, and has been prepared in many different ways under the name of pepsin, as the apparently isolated digestive principle, and, after a great deal of opposition, it has at last been introduced into all the Pharmacopœias.

Pepsin is officinal in the U.S. Pharmacopœia under the name of Pepsinum saccharatum; in the German Pharmacopœia it is simply called Pepsinum. Modes of prepation are not mentioned in either of these Pharmacopœias, but its properties* and tests are given. The U.S. Pharmacopœia has adopted Scheffer's method of testing the remedy and his "standard strength:" 1 part pepsin in 500 parts water, acidulated with $\frac{1}{2}$ per cent. of absolute hydrochloric acid (*i.e.*, $1\frac{1}{2}$ per cent. of the officinal concentrated acid), shall digest 50 parts of hard-boiled albumen within five or six hours, at a temperature of 38 to 40°. The German Pharmacopœia demands double strength, 1 part to dissolve 100 parts of albumen cut into small pieces of the size of a lentil; time, four to six hours. This capability of dissolving albumen is badly expressed in German by the "percentage of pepsin," so that a pepsin which is capable of dissolving a hundred times its weight of albumen is called 100 per cent. pepsin, not because it contains 100 per cent. of pure pepsin. Our officinal pepsin would be, therefore, a 50 per cent. preparation, and one cannot say that the Pharmacopœia makes a very high demand, as there are many pepsins in the market which are much stronger, and which may be changed into a pepsin of 50 per cent., by diluting with sugar of milk. The German Pharmacopœia does not mention any substances by which pepsin may be reduced to a normal strength, but the pepsins which come to us from Germany are also diluted with sugar of milk. The Pharmacopœia also demands that it shall be soluble.

Its power of dissolving albumen changes greatly under different circumstances; and any comparative experiments have to be instituted always under the same conditions. Temperature, percentage of acid, concentration of the pepsin solution, *i.e.*, the quantity of fluid in relation to the pepsin employed, have their determining influence upon the quantity of the albumen dissolved, as also upon the time necessary for its solution; and for the latter (the time) the degree of division of the albumen is especially important, this influence even going so far that the time necessary for the solution of finely-divided albumen amounts only to as many minutes as, according to the Pharmacopœias, hours are necesssary.

The U.S. Pharmacopœia does not mention a word about this division of the albumen, and it can be concluded only from the time given, that the pieces of albumen have to be of about the same size as those which the German Pharmacopœia directs.

For the purpose of comparing the different preparations of pepsin I have made use of the following somewhat different procedure, as it permits their examination within a short time, while according to the process given in the Pharmacopœia, one to two days are necessary.

Albumen, taken from the raw eggs, is beaten to destroy the cellular walls and mixed with water, sulphate of magnesium is dissolved in the fluid, the latter filtered, and the whole is heated after a few drops of acetic acid have been added. The albumen separates as a fine cream-like precipitate, which, on the filter, is freed from the salts by water and then diluted with a definite quantity of fluid containing 0·5 per cent. of absolute hydrochloric acid (5·0 per cent. diluted hydrochloric acid, Ph. U.S., 1883).

For the purpose of comparing the digestive power of different preparations of pepsin, I made solutions each containing 1 per cent. of the respective pepsin, and to this I added 25 centimetres of my albumen-magma (just described), having previously shaken the latter thoroughly and exposed the same to a temperature of 40° C. This temperature was preserved in the water-bath. Solution sets in within fifteen minutes, when 25 or 10 centimetres of the magma are again added to each solution, and this is continued until at last the pepsin does not visibly dissolve any further addition. This point may, near its approach, generally be recognized by the fact that the dissolving process itself goes on more slowly. In case one employs for the different kinds of pepsin relatively 100, 150, 200, 400 centimetres of the albumen-magma, these numbers will express the relative dissolving powers of the different preparations of pepsin in the same numbers. To reduce this value to the albumen, which is coagulated in one whole egg, the percentage of dry substances in the albumen, or in the solution employed, is calculated and then multiplied by seven. (It is to be remarked, that albumen generally contains 14·25 per cent. of dry substance.) The albumen of one egg for every 100 or 150 centimetres fluid may be recommended for practical purposes. It has further to be remarked that the solution, which is finished within a short time, does not represent any peptonization of the albumen; only the first stage of the process of peptonization makes its appearance; the solution takes place by the change of the albumen into syntonin, which is completely precipitated, not by boiling, but on being carefully neutralized with an alkali, or on being boiled with an excess of carbonate of lime or of carbonate of lead. The addition of chloride of sodium to the acid solution also precipitates this syntonin. The perfect metamorphosis into peptone demands considerable time, and is generally not finished at the end of twenty-four hours. The quantity of "peptone" still present as syntonin, and not peptonized, is recognized by the amount of the precipitate produced by ferrocyanide of potassium and acetic acid. The precipitate still appears even if nothing more is thrown down by neutralization; no further sediment takes place.

The different kinds of pepsin of commerce are prepared according to different principles, representing the different phases of experimental empirics, or of the scientific knowledge of this substance. Up to the present time it has not been possible to prepare a perfectly pure pepsin, the preparations sold to-day as such being merely mixtures of certain albuminoid bodies possessing digestive power, and therefore they are looked upon frequently as absolute pepsins, and sold as such by the manufacturer.

No reagents are known by which it would be possible to separate the pepsin from the many other protein-substances and to prepare it in a pure state; nor can pepsin, on the other hand, be separated by precipitating the other albuminoids accompanying it, because when these are precipitated it is carried along with them. But fluids have been obtained possessing a considerable digestive power, and containing, therefore, pepsin, which fact permitted the deduction, that pepsin is *not* precipitated by the well-known precipitants of albuminoids, such as boiling tannic acid, acetate of lead, mercuric chloride, nitrate of silver, acetic acid, or ferrocyanide of potassium; although it may be precipitated by basic acetate of lead, chloride of platinum and alcohol; and even the modes of preparation of the commercial pepsin are based upon the precipitation of albuminoid bodies, to which the real pepsin adheres only mechanically.

The following are some of the processes by which pep-

* Under "Properties of Pepsin," a *lapsus linguæ* has happened in the German Pharmacopœia, copied also in other places; it says, that pepsin does not give a clear solution with water, but that the solution may be made clear by the addition of *two* drops of muriatic acid. That these two drops really refer to the quantity of pepsin equivalent to as much as the "point of a knife" will carry, is left to the imagination of the reader.

sin, each time with different properties, is obtained; properties which in reality do not belong to the digestive ferment itself (which to-day is still hypothetical), but to the accompanying albuminoids forming the greater part of the product:—

1. *Old Method.*—The gastric juice is obtained by scraping the mucous membrane of stomach, extracting with water, filtering, and evaporating at a moderate temperature (Lamatsch's Pepsin). All former pepsins were prepared after this primitive method. To this category belong also the pepsin-wines and elixirs prepared directly by digestion of the finely-cut stomach or its mucous membrane, and the pepsin which is procured by alcohol from the respective digestive fluids.

2. *French Method.*—The extract obtained from the stomach is precipitated with acetate of lead, the precipitate washed, suspended in water, treated with sulphuretted hydrogen, filtered, evaporated to the consistence of syrup, and mixed with starch. (French Codex, Boudault's Pepsin). Since this process precipitates the albuminoid bodies, but not pepsin, only so much of the latter can be effective as has been carried along by the precipitation of the albuminoids. Besides, by this complicated process the effect of the original fluid seems to have been so decidedly diminished that only very little can be expected from the action of this pepsin. The French Codex is satisfied if the "Pepsine amylacée" digests twelve times its weight of albumen; Boudault considers it sufficient when his pepsin digests four times its weight of fibrin.

3. *Scheffer's Method.*—The fact that the acidulated gastric juice is precipitated by a concentrated solution of chloride of sodium as a cream-like substance seemed to prove that it were possible at last to obtain a pure pepsin. However, the pepsin is not precipitated in this manner, but the albuminoid bodies are; and only the property of pepsin to be carried along with precipitates of any character contained in the pepsin-fluid causes the albumen-precipitate of Scheffer to contain pepsin. This albumen is in the condition of syntonin or acid-albumen. The pepsin is prepared by dressing the precipitate, re-dissolving it, and repeating the precipitation, when the mass expressed represents the so-called Pepsinum purum (Scheffer) or, with the addition of sugar of milk, the Pepsinum saccharatum of our own Pharmacopœia.

In this manner, and by careful manipulation, really excellent pepsin preparations may be obtained, the physical properties of which, regarding odour and colour, meet all just demands. The only drawback is, that by the addition of uncertain quantities of sugar of milk, no limits have been put to unlimited dilution, and the latter can to some extent only be controlled by testing how much further dilution any given sample would stand. It is also possible to make a proximate assay of these preparations (which should be called "Saccharum pepsinatum" rather than "Pepsinum saccharatum") by precipitating with chloride of sodium or with picric acid. Some manufacturers of high-grade pepsin indicate directly the quantity of sugar of milk with which their products may be diluted to still merit the name of pepsin, and this shows very strikingly how much sugar of milk is sold under the name of pepsin.

4. The *latest method* for the preparation of not only a very handsome-looking pepsin, but of one possessing a power of digestion far surpassing that of all other preparations of the gastric juice, is that of Carl L. Jensen, formerly of Dakota, now of Philadelphia. This pepsin, to which on account of its appearance the name "crystallized" has wrongly been given, is easily soluble in water without the addition of an acid, is not precipitated by common salt, and turns out to be in every respect a peptone, but of very considerable digestive power; in fact, it is the most powerful pepsin preparation obtainable in the market. I have found Jensen's "Crystallized Pepsin" to be really one of 500 per cent.; at least, if its solubility is tested under most favourable conditions for dissolving albumen.

In contradistinction from those pepsins which are obtained by precipitation with common salt, Jensen's preparations of pepsin contain, besides the ferment which dissolves albumen, another which coagulates milk, the same which exists in rennet and differs from pepsin; this ferment remains partly or wholly dissolved in the saline solution of Scheffer's process. Since it is the peptones proper (but not pepsin, as has been erroneously maintained) which are the "carriers" of the digestive power, we may say that they are prepared by maceration of the stomach and of its mucous membrane in acidulated water at a temperature of 38° to 40° C., by which the albuminoids change into peptones, and can be separated easily, so that by drying on glass they are finally obtained in transparent grains or scales, the superlative properties of which have found their expression in the hyperbolic names given them by their discoverers.

Several manufacturers have heretofore offered quite praiseworthy preparations, which have, however, been dispensed only in consequence of the moral obligation of the apothecary towards the physician; but it must also be admitted that preparations far less valuable, and the disagreeable odour of which already indicated their quality, have also been employed against the better conviction of the apothecary.

The peptone-nature of these preparations is evidenced by the fact that they cannot be precipitated by acetate of lead (unless sulphates are accidentally present), nor by alcohol in acid solution, but by mercuric chloride, nitrate of silver, picric acid or tannic acid. With caustic potash and a little solution of sulphate of copper, the well-known biuret-reaction sets in.

Physiological Deductions.

For the purpose of testing the solvent power of pepsins for albumen, the most favourable conditions have been determined, and it has been found that pepsin without acid does not dissolve albumen at all; but that the addition of hydrochloric acid containing 0·5 per cent. to 0·6 per cent. absolute acid for temperatures of 38° to 40° C., and a less addition, viz., of 0·2–0·3 of the same acid for higher temperatures, 40°–50° C., favours the strongest effect of the pepsin. Somewhat weaker is the action of phosphoric, nitric and sulphuric acids; with lactic acid and the other organic acids, the effect is diminished. Metallic salts and antiseptics, possessing no coagulating effect upon albumen, do not disturb this process of solution.

Temperature higher than the normal temperature of the human body, and a percentage of acid larger than is met with in the human stomach, may be permitted as proper conditions for the artificial production of peptones or for the comparison of the effect of different kinds of pepsin; but for demonstrating the amount of solvent power of a pepsin for therapeutical purposes, it would be necessary to establish the identical conditions actually existing in the human organism, and, under these conditions, the co-efficients of solvent power usually claimed for pepsins are far too high. Besides, for the practical preparation of meat peptones, the experimental results gained in this manner have been proven to be illusions, because the yield of meat peptone represents only a small fraction of the albuminoid substance contained in the muscular substance employed. (I know a manufacturer of peptones, who, without the use of pepsin, manages to get more elegant preparations in larger quantity than they can be obtained by pepsin.)

Pepsin, as well as all other similar ferments which represent products of a continuous physiological function, possesses one great drawback, which cannot be removed. We have invariably at our disposal only that quantity of the pepsin-ferment which the stomach of a slaughtered animal at a certain time either has secreted or prepared in cells. It is questionable, therefore, if the therapeutic employment of this ferment has any advantage at all when given to assist the process of digestion in a dyspeptic stomach, and it is doubtful how much in the cases mostly benefited by the use of the pepsin has to be ascribed to the effect of the latter, and how much to the hydrochloric acid accompanying it.

According to the investigations on the amount of digestive fluid in individuals who, on account of a gastric fistula, were proper subjects for these experiments, this quantity proved to be (in the human organism) 2 kilograms calculated for twenty-four hours. Although the demands on digestion made by the stomach of the hog are totally different, the conditions of the secretion of pepsin are similar to those in man; and the quantity of pepsin which can be obtained at a definite time from a single stomach, even though more could be obtained from that of a hog than from that of man, would, on account of the loss, represent at most a *single dose*.

But experience teaches us that from a good stomach the manufacturer in a favourable case may obtain 4–5 ounces of this saccharated pepsin of the strength as formerly in vogue, viz., $\frac{1}{12}$.

This quantity, according to the method usually employed, was dispensed in one hundred and twenty-five doses of 10 grains each, or in two hundred and fifty doses of 5 grains each. Calculating now the solvent power of the pepsin, we find that 10 grains of pepsin, according to the former statements, could dissolve 120 grains of boiled albumen. For the digestion of 2 ounces of beefsteak, there would be necessary, therefore, 80 grains of pepsin, and for that of $\frac{1}{2}$ pound even 320 grains. To-day, the strength of the preparations of pepsin in the market is far greater; but we must not forget, that hand in hand with the methods of preparation, those of the tests have also improved. Our Pharmacopœia demands that 1 grain of pepsin should dissolve 50 grains of boiled albumen; in the case above mentioned, viz., for the digestion of $\frac{1}{2}$ pound of beefsteak, even of this digestive preparation 80 grains would be necessary to effect solution. It must be admitted that for the pepsins of greatest effect (I myself have found Jensen's pepsin as probably one of 500 degrees) only the 500th part would be necessary for the same purpose; and 1 ounce of a protein-substance, therefore, would demand 1 grain of this pepsin only; but as mentioned above, even in the best preparations the percentage of peptones obtained during the process from those really present is a very limited one, and the general objection made above is not answered even by the fact that very active pepsin preparations are actually obtained.

The logical deduction, therefore, from these observations would be, that the small doses of pepsin of feeble digestive power should be replaced by very much larger doses of those preparations of pepsin which are recognized as the best, whenever any practical results are to be expected and looked for; that all favourable conditions which are known experimentally to produce a rapid and perfect solution of the albuminoids should never be lost sight of when the remedy is employed for medicinal purposes, and that this effect ceases when pepsin is administered either simultaneously with or in combination with alkalies, a rule which, in spite of frequent warning, is, up to this day, still disregarded by many.

THE CHEMICAL COMPOSITION OF OIL OF BIRCH (BETULA LENTA, LIN.).*

BY H. P. PETTIGREW.

A thorough chemical investigation of the composition of the volatile oil of birch has never been made, although in 1844 Procter† first found it to contain salicylic acid, and from the similarity of the properties of this oil with those of oil of gaultheria he suggested the idea of an analogous chemical composition of the two oils.

Nothing more was written upon the subject until 1882, when Mr. G. W. Kennedy,* of Pottsville, made some experiments with it, by which results were obtained, indicating the presence of salicylic acid, and by which the identity of the oil with that of gaultheria was presumed.

In 1843, Procter made a series of experiments with oil of gaultheria, and in the following year M. Cahours† made a careful analysis of it, and found it to consist of salicylate of methyl, together with 10 per cent. of a terpene.

The oil used in this analysis was obtained through the kindness of Mr. Kennedy, and, being distilled by a friend of his, an oil of absolute purity was thus guaranteed.

The oil of birch when freshly distilled is a bright and colourless liquid, of considerable refractive power; it possesses a very agreeable and fragrant odour, closely resembling that of gaultheria, although a difference can be perceived when the two oils are compared. With age, the oil acquires a reddish colour, of which, however, it is deprived by distillation. It has a specific gravity of 1·180 at 15° C. (59° F.), and its boiling point is constant at 218° C. (424·4° F.).

A portion of the oil when shaken with a concentrated solution of sodium bisulphite afforded no crystalline compound, thus proving the absence of an aldehyde.

The plan of analysis adopted was as follows:—

To 100 grams of the oil contained in a half litre flask provided with an inverted condenser a concentrated solution of 50 grams of potassium hydrate was added, which is somewhat more than the theoretical quantity required for the decomposition of the oil, and the mixture boiled for six hours upon a sand-bath. At the end of this time the oil was completely decomposed, and a clear liquid was obtained, without the separation of any oily layer, and also affording none upon dilution with water or upon supersaturation with an acid. This observation demonstrated conclusively the absence of a terpene, which, had such been present, would have remained undecomposed by the caustic alkali, and become separated at once or upon subsequent dilution of the strongly alkaline liquid with water. In this manner 400 grams of the oil were treated.

The resulting liquids were then distilled from a sand-bath until one-fourth of the entire amount had passed over; this distillate was then redistilled from a sand-bath; collecting one-fourth as before, and the latter distillate, which would contain all the methyl-alcohol, was then distilled from a water-bath, and further rectified and deprived of water by distilling twice from quick lime. This liquid thus obtained then possessed the unmistakable odour of methyl-alcohol, and corresponded to it in its specific gravity and boiling point.

The liquid remaining from the first distillation, which would contain the salicylic acid combined with the potassium, was then slightly supersaturated with hydrochloric acid, whereby a dense white precipitate of salicylic acid was obtained. This was then washed with a little water, dried by exposure to the air, and purified by crystallization from hot petroleum benzin, from which it was deposited in light, colourless and lustrous crystals.

Upon adding a concentrated solution of potassium or sodium hydrate to the oil, as had been previously observed by Procter (*loc. cit.*, 1844, p. 243), combination immediately ensues, with liberation of heat, and a white, crystalline compound is formed, which is decomposed by acids, with a separation of the original oil.

The composition of these compounds with the alkalies, in which the hydrogen atom of the phenol group of methyl salicylate is replaced by potassium, sodium, etc., and their decomposition by the action of an acid with the regeneration of the original oil, may perhaps be more clearly seen when expressed by an equation, as follows:—

* *Am. Journ. Pharm.*, 4 ser., vol. xii, 1882, page 49.

† *Journ de Pharm et Chimie*, Mai, 1843. Abstracted by *Am. Journ. Pharm.*, 2 ser., vol. ix., 1844.

$$C_6H_4\begin{cases}OK \\ CO-OCH_3\end{cases} + HCl = C_6H_4\begin{cases}OH \\ CO-OCH_3\end{cases} + KCl$$

It is worthy of note that the specific gravity of oil of gaultheria, as stated in the United States Pharmacopœia (1880), corresponds precisely with that of oil of birch, while the specific gravity of an authentic specimen of oil of gaultheria in the possession of Professor Maisch was found to be but 1·0318 at 22° C.

The lower specific gravity of oil of gaultheria may easily be explained by the presence in the latter of a terpene which is lighter than water.

The results obtained by the present investigation may, therefore, be briefly summarized as follows:—

I. The volatile oil of birch is not identical with the oil of gaultheria, in that it consists entirely of salicylate of methyl, and contains no terpene.

II. The specific gravity of oil of gaultheria is not 1·180, as stated in the United States Pharmacopœia, but 1·0318; the former being the specific gravity of oil of birch, which, as is known, is often indiscriminately sold and employed as oil of gaultheria.

In conclusion, the writer desires to state that he has commenced the analysis of pure oil of gaultheria, and that the terpene which it contains, but of which at present so little is known, will be submitted to further investigation.

THE SPECIFIC GRAVITY OF CONCENTRATED SULPHURIC ACID.*

The relation between specific gravity and percentage of absolute acid, in the case of sulphuric acid, formed one of the subjects of extended discussion during the last revision of the United States Pharmacopœia. A special committee of the National Academy of Sciences is at present also engaged with the examination of a similar question, namely, the establishment of a reliable scale and a report on the feasibility of abolishing Baumé's scale altogether or at least adopting a fixed scientific basis for it.

During the examination of the various tables of the strength of sulphuric acid by the Committee of Revision, it became evident that the tables heretofore usually relied on (Ure's, etc.), were entirely unreliable. The only one which was based on elaborate scientific experiment was that constructed by Kolb, of Mühlhausen. And this was the table finally selected. To demonstrate the relative coincidence or divergence of the different tables, the writer of this article constructed for the Committee of Revision a series of curves, on one and the same table, in which the specific gravities were entered upon the ordinate—and the percentages upon the abscissaxis. While curves for the weaker acid often coincided, they began to diverge more and more as the strength of the acid increased, the only one which remained somewhat in harmony with Kolb's being that of Bineau. The curve is quite normal—with the exception of a few points which probably mark definite hydrates—until a strength of about 88 per cent. is reached, when it begins to ascend rapidly so that there is but little difference of specific gravity for the highest strength of acid left.

Kolb s table, unfortunately, omits the very section of the curve involved in this rapid increase, inasmuch as he gives no specific gravity or percentage between 1·819 (89·7 per cent.) and 1·842 (100 per cent.).

Professor G. Lunge, of Zürich, and Mr. P. Naef, have lately made a renewed investigation of this subject, under observance of all precautions and corrections insuring a reliable result. The thorough familiarity of Professor Lunge with this subject renders his contribution particularly valuable, as it probably settles the question permanently.

Professor Lunge and Mr. Naef find that Kolb's figures coincide, below 90 per cent., with the values found by themselves so closely that they may be regarded as practically correct. Two observations were, however, made which are of importance. Kolb, namely, states that he succeeded, by careful repeated distillation, in obtaining an acid containing 99·72 per cent. of sulphuric anhydride. No other chemist had, before him, succeeded in this, and even Lunge and Naef could not obtain, by the most careful evaporation *in vacuo*, a stronger acid (as *residue*) than 98·57 per cent. Further it was shown that the specific gravity of the latter acid (98·57 per cent.) as obtained by evaporation agreed almost absolutely (within 0·0003) with an acid prepared by mixing the calculated quantity of anhydrous sulphuric acid with a somewhat weaker acid; and that an acid of the latter kind (that is, one containing an excess of SO_3) as well as an acid approaching 100 per cent. has a *lower* specific gravity than a somewhat weaker acid, which observation confirms similar ones already made by F. and W. Kohlrausch.

The utility of Kolb's table being somewhat impaired by the absence of any data for the strongest sulphuric acid, Lunge and Naef have now filled out the gap by the construction of the following table, the last column of which gives the specific gravity and degrees by Baumé's scale of a commercial acid made at Uetikon, on the lake of Zürich:—

Table of Percentage and Specific Gravity of the Strongest Sulphuric Acid at 15° C. (59° F.), reduced to Water at 4° C. and a Vacuum.

Percentage H_2SO_4.	Pure acid.	Commercial acid (Uetikon).	
	Spec. grav.	Spec. grav.	Baumé.
90	1·8185	1·8202	65·1°
*90·20	1·8195	...	...
*90·29	...	1·8219	...
91	1·8241	1·8254	65·4
*91·48	1·8271	...	...
92	1·8294	1·8306	65·6
*92·83	1·8334	...	...
93	1·8339	1·8346	65·8
94	1·8372	1·8374	65·9
*94·09	...	1·8375	...
*94·84	1·8387	...	...
95	1·8390	1·8397	66
*95·26	...	1·8404	66
*95·97	1·8406	...	...
96	1·8406	...	...
97	1·8410	...	...
*97·70	1·8413	...	...
97·75	...	1·8464†	66·2
98	1·8412	...	...
*98·39	1·8406‡	...	...
*98·66	1·8409§	...	...
99	1·8403	...	...
*99·47	1·8395	...	...
*100	1·8384	...	...

Below 90 per cent., Kolb's table may be used unhesitatingly for commercial acids.

* These figures were directly determined; the others by graphic interpolation.

† Acid prepared, at Griesheim, by direct evaporation on a large scale.

‡ Prepared by mixing ordinary strong acid with anhydride.

§ Prepared by direct evaporation of ordinary strong acid.

FLUID EXTRACT OF SENEGA.*

BY H. J. ROSE.

The tendency of this extract to gelatinize and form a copious precipitate has provoked considerable investigation, and the remedies advocated have, in my experience, but slightly modified the evil. The alkaline treatment, recommended by Dr. Squibb and others, while mitigating the first-named evil, does not seem to prevent the formation of a precipitate, the deposit proceeding slowly, for a considerable time, sometimes for months. Without criticizing the methods recommended by many would-be doctors for the evil, or giving details of the different menstrua employed, and their relative merits, I will only refer to two papers read at the New York State Pharmaceutical Association, which have led me to think that the result of my experiments to find a suitable menstruum would be acceptable. In these experiments I have endeavoured to avoid the application of heat, and to preserve the active constituents of the root in an unchanged condition.

The first process, recommended by C. W. Holmes, of Elmira, that of exhausting a pound of the root with dilute alcohol, evaporating to 11 ounces, filtering and washing the residue, must surely leave a large portion of the polygalin on the filter. The other process, that of Professor P. W. Bedford, is much better, viz: heating the hydro-alcoholic solution quickly to boiling, and then filtering. The only objection is the application of heat, which he states could hardly be accepted in a fluid extract, and gives in preference the United States process in which ammonia is used, furnishing a product which is said to be unexceptionable in every respect. My experience is that this preparation does throw down a precipitate continuously.

I have found that the addition of a small quantity of neutral spirit of nitrous ether to the menstruum has in my hands proved a very effectual remedy for both the troubles complained of, forming a stable product, without the use of glycerine or alkalies, or the application of heat. The menstruum used was:—

Alcohol	7 parts.
Spirit of nitrous ether	2 „
Water	7 „

and the process that of the U.S.P. The product has kept with me some ten months without deposit, and I should like others to try the same and report results.

The idea was suggested by some experiments made on the deposit formed in the fluid extract. Various solvents were tried, among others, the spirits of nitre, which appeared to be quite effective. Its preservative action is still more marked.

SOAP VARNISHES.†

BY E. ANDRES.

This varnish, owing to its cheapness, complete resistance to water, and considerable elasticity, is of value for many purposes. To make it, boil good tallow soap with soft water until dissolved, and filter while hot through cloths, heat again, add an equal volume of water and a boiling solution of alum as long as an alumina salt is precipitated. Let the stearate of alumina settle from off the water, and wash the precipitate thoroughly, then dry and heat on a water-bath until transparent. Finally, stir the preparation into turpentine, heated nearly to boiling until a solution is made of the consistency of thick varnish, which can afterwards be thinned with more turpentine if required. Johnson's waterproof varnish for paper and cloth is made by dissolving copperas in water, adding soap solution thereto and straining off the precipitated stearate of iron. If this be dissolved in bisulphide of carbon or benzole, a waterproof varnish is obtained. For a white varnish, use alum instead of copperas. Varnish for gilding is made as follows: 50 parts soda are dissolved in 100 parts water in a copper vessel heated to boiling, and 100 parts powdered resin stirred in and boiled for two or three hours until perfectly clear. Let it cool, pour off the supernatant water from the heavy, viscous, resin soap, add 100 parts of fresh water and 15 parts of steeped glue, and heat till the whole is dissolved. This makes a quick drying varnish; for a slow drying varnish add 10 to 20 parts glycerine of 28° B. The above resin soap, mixed with about 5 per cent. ammonia, forms a very cheap and durable vehicle for paints. Waterglass paints are only successful when mixed in small quantities and applied immediately.

CANTHARIDIN AND ITS USES.*

E. Dietrich, manufacturer of plasters, dressings, etc., in Helfenberg, advocates the abandonment of cantharides as an ingredient in blistering tissues and the employment in its place of the active principle cantharidin.

The best solvent for this principle is formic acid, which itself occurs in cantharides; the stronger the acid the greater is its solvent action.

If cantharidin is to be dissolved in collodion, oil, or the mass of the plaster, it is advisable to rub it first to a very smooth paste with oil. In this shape it is soluble in collodion by mere shaking; in oil and plaster it dissolves on being heated for half an hour to 80° C. (176° F.).

Cantharidal Collodium.

Cantharidin	$\frac{1}{20}$ gr.
Collodion	15 grs.
Rape oil (as colouring)	$\frac{3}{4}$ gr.

Ordinary Cantharidal Plaster.

Cantharidin	$\frac{1}{16}$ gr.
Suet	3 grs.
Yellow wax	12 grs.
Turpentine	3 grs.

Perpetual Cantharidal Plaster.

Cantharidin	$\frac{1}{64}$ gr.
Resin	10 grs.
Yellow wax	8 grs.
Turpentine	5 grs.
Suet	3 grs.
Euphorbium, powd.	1 gr.

Cantharidal Oil.

Cantharidin	$\frac{1}{20}$ gr.
Rape oil	15 grs.

Cantharidal Ointment.

Cantharidin	$\frac{1}{9}$ gr.
Yellow wax	45 grs.
Olive oil	100 grs.

Unguentum Acre.

Cantharidin	$\frac{1}{32}$ gr.
Yellow wax	$1\frac{1}{2}$ gr.
Resin	3 grs.
Turpentine	6 grs.
Lard	20 grs.
Euphorbium, powd.	1 gr.

In all these cases the relation of cantharidin to Spanish flies is ample, about 1 to 200. In the case of some preparations, as the oil and ointment, loss is occasioned by heat, but this loss is made up by a proportionately larger quantity.

THE INLAND REVENUE COMMISSIONERS' REPORT.

THE reports presented annually by the Commissioners of Inland Revenue to the Lords of Her Majesty's Treasury always contain a mass of information for statisticians interested in ascertaining the exact way in which a large proportion of the current income of the country is made up, but they also usually refer incidentally to a large number of subjects that are more or less connected with the business of many readers of this Journal. In recent years this has been especially the case with respect to the appendix devoted to the account of the work done in the Laboratory at Somerset House, and the Twenty-Sixth Report, which has been issued during the past week, is no exception to the rule. It shows that the various departments of the State are becoming increasingly aware of the services that can be rendered by the chemist, since the number of samples analysed during the year ending March 31st last was 24,312, or 4356 above the average of the previous three years, and 10,000 more than were submitted for analysis in the year 1873. Hitherto the additional work has been met by an increase in the staff of temporary assistants, but this has necessitated the withdrawal of first class analysts from their ordinary work for the purpose of supervision, and as the higher class of analytical work has increased concurrently some considerable embarrassment and hindrance to business has resulted, which induces the Principal of the Laboratory to urge the desirability, in the public interest, of the provision of some more certain and reliable assistance.

Among the most responsible work done in the Laboratory are the references under the "Sale of Foods and Drugs Act" in cases of prosecution where the evidence of a public analyst is disputed. During the year there were thirty samples so referred, including milk, butter, whisky, gin, rum, beer, bread, coffee, "sweet nitre," ketchup, arrowroot and ground ginger. Of these seventeen were samples of milk, twelve being alleged to have been watered and five deprived of a portion of their cream. In two-thirds of the "watering" cases the results obtained confirmed the conclusions of the public analyst, but in four out of five of the "cream" cases the percentage of fat was found to range from 2·49 to 2·79, and as the lowest of these figures was considered to be practically equal to the minimum limit recommended by the Society of Public Analysts, it was inferred that the respective local analysts had failed to extract the whole of the fat. There were two samples of butter alleged to contain foreign fat, but in neither case was the department able to confirm the statement. With respect to four samples of spirit, three were found to agree with the description of the local analyst, but in the fourth it was considered probable that the obscuration of strength caused by the presence of sweetening and colouring matters had not been taken into account. A sample of beer was alleged to have been adulterated with common salt, but concerning this the Report says that the public analyst had evidently followed the practice of calculating the amount of salt from the chlorine present, without ascertaining whether or not there was sufficient sodium in the beer to form, with the chlorine, the quantity of common salt reported. A sample of bread was found to contain the unusually large proportion of 39 grains of alum per 4 lb. loaf. A sample of "sweet nitre" is referred to as affording an illustration of the difficulty sometimes felt in giving a certificate which shall be equally just to the prosecutor and the defendant. The London Pharmacopœia process for "sweet spirit of nitre" is described and the modification of it in the British Pharmacopœia under the name of "spirit of nitrous ether," which is spoken of as containing "a large "and less variable proportion of nitrous ether than "'sweet nitre' prepared by the process laid down "in 1851." But, recognizing the fact that the first-named process is still extensively followed, the department reported that "the results of an ana-"lysis agreed with those of 'sweet nitre' pre-"pared according to a formula given in the "London Pharmacopœia of 1851." The other samples referred were one of coffee which contained nearly half its weight of chicory, one of ketchup of low strength and in a state of decomposition, one of arrowroot containing 40 per cent. of sago flour, and one of ground ginger containing 20 per cent. of ground rice. It will, therefore, be seen from the foregoing that in thirteen out of the thirty cases of disputed analysis referred by magistrates to the Inland Revenue Laboratory during the year the department was unable to confirm the reports of the local analysts upon which prosecutions had been based.

Besides the foregoing analyses and those conducted in the Laboratory which have an immediate bearing upon the collection of revenue, a large number are made for the different public departments, especially of articles which are the subject of contract, and which evidently require that a sharp supervision should be exercised over them. Thus, out of nine samples of treacle that had been supplied to the Admiralty as derived from cane sugar, for the use of the boys on board Her Majesty's training ships, all but one were found to have been derived more or less from beet sugar and to contain too large a proportion of alkaline salts to allow of their being safely used as regular articles of diet. An unsightly batch of pickles was found to have been made with a "vinegar" consisting chiefly of pyroligneous acid, and the traces of iron usually present in such acid had combined with tannic acid from the wood of the cask to form an ink which had of course discoloured the pickles. Turning to another class of articles, out of five pieces of electroplated ware only one had deposited upon it the proper proportion of silver. For the Board of Trade upwards of five hundred samples of lime juice and lemon juice were examined, representing upwards of seven thousand gallons of the former and sixty-seven thousand gallons of the latter. The report states that the marked improvement in the quality of the juice which had been observed in the previous year had not only been maintained, but had become even more decided. The samples rejected amounted to only 3 per cent. of the lime juice and 7 per cent. of the lemon juice, a proportion lower than in any preceding year. Nineteen samples of fortified juice were analysed, and four were rejected on the ground of unsoundness, presence of pulpy matter, or excess of spirit.

It will not be necessary to refer here to the general statistics contained in the Report, especially as the most important were dealt with by the Chancellor of the Exchequer when introducing his Budget to the House of Commons. But it may be mentioned that the falling off in the consumption of spirit as a beverage, which has been the subject of comment as indicating an improvement in the habits of the people, is coincident with a continued increase in the quantity of spirit methylated for use in the arts and manufactures. Eight samples of naphtha intended for "methylating," representing more than a thousand gallons, were rejected on the ground that it was not sufficiently offensive in odour and taste to render the resulting methylated spirit unfit for drinking purposes. In connection with a decrease in the beer revenue, and the possibility of this having been affected by the failure of the hop crop last year, it is remarked that it is believed that other vegetable substances have been used by some brewers together with hops, as "hop supplements," but that nothing has yet been found that possesses the aromatic and preservative properties which have for so long made hops an essential ingredient in all good beer. In connection with the subject of drinks, it is worthy of note that 642 samples of various "temperance beverages," such as botanic beer, herb beer, tonic ale, etc., were examined, and these ranged in contents of proof spirit from none to 8·1 per cent. Lastly, the revenue from the issue of patent medicine licences during the year amounted to £4851, and from patent medicine stamps to £154,439, showing in the latter item an increase of £9555 as compared with the previous year.

Should any of our readers share the intense susceptibility of the "Own Correspondent" of a contemporary, who recognized in the absence, on the plea of illness, of the Archduke Carl Ludwig from the ceremony at the opening of the late International Pharmaceutical Exhibition an indication that pharmacy had been "once more snubbed by royalty," they may find perhaps some comfort in the fact that the Emperor of Austria was present towards its close. His Majesty had signified on the previous day his intention of visiting the exhibition on Friday, the 24th, and precisely at the hour appointed, eleven o'clock, his carriage was driven up to the entrance, where he was received by the President and members of the Executive Committee and the Jurors, and from whence he passed into the centre of the building and took his stand near the exhibit of military medicine chests from the Imperial War Department. The President delivered a short address to His Majesty and then presented to him the members of the Committee and some of the Jurors, the representative of this country being Mr. Thomas Greenish. His Majesty passed round the exhibition, and left after a stay of about an hour and a half.

* * *

In connection with this exhibition we may mention that we have received a copy of the list of awards by the jurors, and find that each of the three British exhibitors has received some recognition of the merits of his exhibit, Professor Attfield, who sent a set of the ten editions of his 'Manual,' having been awarded a gold medal and Messrs. Fletcher, Fletcher and Stevenson and Mr. W. Martindale silver medals.

* * *

Professor Attfield has been elected an Honorary Member of the Pharmaceutical Society of New South Wales.

* * *

The French Association for the advancement of Science has recently held its twelfth annual meeting at Rouen, and the managers of the Association seem certainly to have reason to be satisfied with the progress it has made, for according to M. Masson, the Treasurer, its accumulated capital already equals that of its elder sister, the British Association, whilst it has five hundred more members. But M. Masson left the sure ground of facts for the region of prophecy, concerning which some good advice has been given, and went on to say: "When we have reached our fifty-second year we shall certainly be able to dispose of a capital of several millions, and the French Association, which already draws to its bosom so large a number of illustrious personalities, will enjoy an immense influence over the scientific progress of our country and consequently of the entire world."

* * *

According to the circular of the Entertainment Committee, a very large attendance of members is expected at the meeting of the American Pharmaceutical Association in Washington next month, arrangements having been made for the reception of over six hundred persons. The meeting, which will be held in the Smithsonian Institution in the national capital, will commence at 3 p.m. on the 11th instant, and the concluding excursion will take place on the 15th.

In the United States, as in this country, the stupidity of the public in preferring the advertized nostrums of quacks to the medicines of regular medical practitioners is a fertile cause of scolding by orthodox writers, whose lucubrations sometimes show a ludicrous straining after effect. Thus one contemporary laments that "In spite of learned physicians, the ignorant multitude, like swine possessed of devils, rush violently into the sea of patent medicines and perish. They are not capable of distinguishing between the true and the false, sham work and the effects of real specifics. They prefer the advertised quack to be tied like a millstone around their neck, and to be cast into the sea, instead of resorting to the pharmacopœia," etc., etc. The *St. Louis Druggist* rather cruelly but pertinently remarks upon this, "Let the good work go on! The more advertised quacks that are tied like millstones around the necks of the public and cast into the sea, the better it will be for those of us who are left."

* * *

In May last, a French pharmacist, against whom an action for supplying a lady with rather considerable quantities of morphia without requiring a fresh medical authorization each time had been brought by the lady's husband, was condemned to pay a penalty of 1000 francs and 2000 francs damages to the husband as well as to undergo eight days' imprisonment. Upon appeal, this severe sentence has just been somewhat mitigated, the penalty having been reduced from 1000 francs to 500, but the amount of damages and imprisonment have been maintained. Commenting upon this case a writer in the *Répertoire* says that although with the majority of poisonous substances it would be difficult for the pharmacist to refuse the repetition of a prescription upon the solicitation of a customer, it will be necessary in the face of this judgment to safeguard himself by requiring that the physician shall endorse upon the prescription the length of time during which it is to be repeated and at what intervals.

* * *

A vacancy in the division of physics, medical chemistry and pharmacy of the Academy of Medicine has recently been filled by the election of M. Andouard, of Nantes, whose 'Nouveaux Eléments de Pharmacie' is probably known to some of our readers.

* * *

At a meeting of the Aberdeen University Court on Tuesday last, Dr. Matthew Hay, Demonstrator of Practical Materia Medica in the University of Edinburgh, was appointed to succeed Dr. Ogston in the Chair of Medical Logic and Jurisprudence.

* * *

According to a recent census, quoted by the *Medical Times and Gazette*, there are in Paris and the communes of the department of the Seine 1915 doctors of medicine, 12 doctors of surgery, 83 officers of health, 43 foreign doctors, 1500 midwives, 845 pharmacists and 95 veterinary doctors. These figures are, of course, exclusive of illegal practitioners.

* * *

A weakness for "picking and stealing" bits of information, without acknowledgment as to their source, has placed an Irish medical contemporary in the ludicrous position of fathering a mistaken announcement made in another journal that the British Association will meet this month in "the New Dominion." We refrain from mentioning the names of the originator and endorser of the *canard*.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, August 1, 1883.

Present—Professor Tichborne, President, Dr. Aquilla Smith, Vice-President, Dr. Collins, Dr. R. Montgomery, Messrs. Brunker, Doran, Draper, Grindley, Hayes, Hodgson, Wells, jun.

The minutes of the July meeting were read and signed.

Letters were read from Mr. Patrick S. Moriarty, of Killarney, and Mr. Laurence H. Elmore, of Dundalk, both of whom have passed the preliminary examination of this Society, asking to be allowed to come up for their final examination, the former in nine months, and the latter in six months, from the time at which they passed the preliminary.

It was resolved that they be informed that their requests cannot be granted, inasmuch as the regulations require that twelve months must elapse between the two examinations, except in the case of candidates who have passed (at least two years before) one of the preliminary examinations recognized by the General Medical Council.

Read a letter from Mr. Philip Princep, Secretary to the British Pharmaceutical Conference, asking for the names of the delegates from this Society to the approaching Conference at Southport, in September.

It was decided that delegates should be appointed at the next monthly meeting of the Council to be held on September 5.

Read a report from the Law Committee on the petition and letter forwarded by the Clerk of the Privy Council, by direction of that Council, for any observations which this Council might choose to make thereupon (see report of July meeting in *Pharmaceutical Journal* of July 14, 1883, p. 36).

The report included a draft letter to be sent by the Registrar to Dr. Kaye, in reply to the petition and letter forwarded by him.

When the petition and draft letter had been read over, it was proposed by Mr. W. F. Wells, jun., and seconded by Mr. Grindley:—

"That the following paragraph, 'The proposed grade of Registered Druggists, whose licence would empower them to sell poisons, but not dispense medical prescriptions, might in the opinion of this Council be extended with advantage to persons who should pass an examination as to their knowledge of the nature and properties of poisonous drugs and chemicals. Under the present powers of this Council there is no such examination possible,' be omitted."

The motion was lost on a division, two voting for, and eight against it.

The adoption of the draft letter, as sent up by the Committee, was then proposed, seconded, and carried.

Read a report from the House Committee, stating that Mr. Francis O'Neill had accepted the proposal of the Committee for the tenancy of three rooms in his house, No. 11, Harcourt Street, Dublin, for a term of ten years, at a rent of fifty pounds a year, with an additional sum of nine pounds a year for attendance. The Committee recommended that a sum of £160 be placed at their disposal for the purchase of furniture, etc., for these apartments; and submitted the draft of an agreement to be signed by the President and by Mr. O'Neill, specifying the conditions upon which the premises are to be held.

Proposed by Dr. Montgomery, seconded by Mr. Doran, and resolved:—

"That the sum of £160, asked for by the Committee, as essential for furnishing the new rooms in Harcourt Street be granted, leaving the disposal of it to their discretion."

The report of the examination for the licence as Pharmaceutical Chemist, held on July 4th and 5th, was laid on the table. Seven candidates presented themselves, of whom one withdrew, one was rejected, and the following five passed—

Robert Armstrong, Cootehill.
Richard Godley, Tralee.
Thomas Lemon, Markethill, Co. Armagh.
John Cooper Francis Meyler, 7 Wellington Place, Dublin.
Gerald Leahy Stack, Listowel, Co. Kerry.

Mr. Hayes, according to notice given, moved the following, which was seconded by Mr. Brunker, and adopted:—

"That the resolution of March 5th, 1879 (see 'Calendar' for 1883, pages 55 and 83) be altered to read, after the word 'Ireland', 'or Registered Chemist and Druggist of Great Britain.'"

[N.B. The resolution as now amended sanctions the acceptance from candidates of certificates for compounding given by registered Chemists and Druggists of Great Britain.]

Some bills were ordered for payment, and the Council then rose.

Provincial Transactions.

HAWICK PHARMACEUTICAL ASSOCIATION.

The third meeting of this Association was held on Wednesday, the 8th inst., when there was a good attendance, Mr. Dechan occupying the chair.

The first business of the meeting was the reading of a paper on "Lime Water," by Mr. T. Maben, Pharmaceutical Chemist. At the outset, Mr. Maben gave the results of a series of analyses of commercial samples of lime water, from which it appeared there was considerable variation in the quality of this preparation. The strength required by the British Pharmacopœia is ·56 grain CaO per fluid ounce at 60° F., and there were a number of this strength, but the majority were under ·5 grain, while one specimen reached as low a point as ·3 grain. Discussing the causes of these variations, Mr. Maben showed that they might be traced to several sources, viz., the lime, the water, the method of preservation and temperature. It was of the utmost importance to have calcic hydrate to begin with, and not a mixture of hydrate and carbonate. The hydrate absorbs CO_2 with great rapidity, and unless very carefully preserved, it would be found to be in a short time largely contaminated with carbonate. Again, it is believed to be a not uncommon practice to use ordinary water in making this preparation, but in very many cases it will be impossible to obtain lime water of full strength by so doing and therefore distilled water only should be employed. It is found that lime water if exposed to the atmosphere, as in a half-empty bottle, very rapidly absorbs carbonic dioxide, and immediately becomes weakened in consequence. Lastly, the changes of temperature exert a considerable influence. It is well known that salts of lime are less soluble in hot than in cold water, and even at an increase of 5° F. a considerable difference is noticed, the point of saturation being reached at ·54 grain CaO per fluid ounce. The solubility gradually diminishes up to 80° F., when ·52 grain is found to saturate each ounce of water. The practical considerations naturally arising out of this fact are that great care should be exercised in keeping all the stock and shop bottles perfectly air-tight and as cool as possible; otherwise it is next to impossible to supply the public with a perfect lime water.

Mr. W. P. Kennedy then delivered a lecture on "The Spectroscope and Spectrum Analysis." The lecturer first gave a short account of the hypothesis concerning light, afterwards describing the spectroscope and the discovery of spectrum analysis, by which we are now able to ascertain the composition of the furthest distant stars, and explaining practically its application as a means of detecting metals in qualitative analysis. Mr. Kennedy then gave an exceedingly interesting description of the rainband spectroscope, by which we are almost able to predict with certainty what the weather of to-morrow will be.

Votes of thanks having been heartily awarded to Mr. Maben and Mr. Kennedy for their papers, the Secretary intimated the arrangements for the Botanical Class, and the next meeting of the Association.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Solid and Liquid Illuminating Agents.*

BY LEOPOLD FIELD, F.C.S.

Lecture IV.

We now leave that part of our subject pertaining to unmanufactured materials, and come to consider what difference chemical treatment is able to produce in them. As mentioned several times already, spermaceti and wax are incapable of improvement by decomposition, but tallow and palm oil only become true illuminators when chemistry has divested them of their grosser components. It is singular to remark how prominent a part France has played in the history of lamps and candles. We have the Sieur de Brez inventing mould candles; Cambacères, who introduced plaited wick, perhaps as vital and essential an improvement as any; Argand and Carcel, the fathers of the lamp; and last, and greatest, Chevreul, the discoverer of stearine. It is also worthy of note that all the great inventions which confer a lustre on this century took their rise in the period intervening between the first and second great French Revolutions. The steam-engine, the railway, the steamship, the electric telegraph, gas lighting, the penny postage, and the abolition of slavery, are all events in that era. I mention the latter with a purpose, because Chevreul's discoveries have tended more to the bringing about of that blessing than missionary labours or Acts of Parliament. This assertion will be proved as we proceed. For the present we will consider what these labours were. In 1811, Chevreul's researches commenced; his first paper saw the light in 1813. In this he announced that fatty bodies were of a composite nature; that tallow, lard, and other fats were not pure compounds, but, in the first place, *mixtures* of hard and soft materials which, again, were *compounds* of a fatty acid with a substance called glycerine. This discovery is the keynote of the stearine industry; for, until the comparatively uninflammable glycerine is severed from the brilliantly burning fatty acid, and devoted to its own valuable purposes, neither of them can be said to fulfil its legitimate intention. The efforts of all labourers in this field are still directed to the obtaining a fatty acid free from glycerine in the cheapest manner and greatest quantity. Chevreul published paper after paper, attacking and decomposing one fatty substance after another; until, in 1823, he published the whole of his labours under the title of 'Chemical Researches on Fatty Bodies of Animal Origin,' perhaps as fine a monument of untiring perseverance, combined with supreme skill, as chemistry has to boast of. But, so far, the tendency of Chevreul's work had been entirely scientific, nor had he attempted to obtain any pecuniary result from his labours. From a keen eye like his own, however, it was impossible that the intrinsic value of his discoveries would long remain concealed. Accordingly, in 1825, he, with Gay Lussac, started a

* Cantor Lectures: Reprinted from the *Journal of the Society of Arts.*

factory for the manufacture of stearic acid, under the protection of patents. But chemical knowledge and technical—or rather commercial—success do not always go hand-in-hand. Chevreul's enterprise proved a failure; and it remained for M. de Milly to reap the harvest which the great chemist had sown. In 1832, M. de Milly commenced manufacturing stearine candles near the Barrière de l'Etoile, and produced some very excellent candles which were called by that name. The Société d'Encouragement, of Paris, in the same year, were moved, in consideration of Chevreul's labours, to offer a premium of 4000 francs to the manufacturer who should produce two tons of candles under the following conditions:—The price not to exceed 9*d.* per lb.; the light to be, weight for weight, equal in amount and brilliancy to that of wax candles; neither to smell, smoke, nor gutter, and to be hard and dry; the multiplying point not to be below 122° Fahr. Messrs. Motard and Milly were successful in their endeavours to obtain this prize, up to a certain point. They produced candles complying in all respects with the conditions, except in that of price, which was nearly double the amount stipulated. In awarding a silver medal to the claimants, the Society expressed a hope that the money prize would be carried off.

It is here necessary to consider the results published by Chevreul, and applied by M. Milly. You have heard that oils are divided into "fixed" and "essential," and that the latter are not qualified to be considered as luminants, differing totally in constitution from the former. I may just remark that as nearly every natural product yields a separate definite acid, so also it contains a characteristic essential oil. I need scarcely remind you how keen the sense of smell is, which enables us readily to distinguish the hundreds of different odours we come across in daily life, and nearly each of these is due to an essential oil. But the fixed oils can be defined as compounds of a fatty acid with alcohol, either glycerine, as in true fats, or ethyl, cetyl, etc., in wax. Tallow, the most important, is a mixture of stearine and oleine. By simple pressure the latter separates in the form of a brown oil. This is now extensively used in the art of making butter, but is not to be confounded with the commercial oleine used by soapmakers, which is really oleic acid. Stearine consists of stearic acid and glycerine. Palm oil, which is becoming as important a substance as tallow itself, consists mainly of palmitine, which is palmitic acid and glycerine. In order to effect the separation of these bodies to obtain the palmitic, stearic, and oleic acids in a utilizable condition, three processes are available; the first is that of Chevreul, adopted by M. Milly, called the *saponification* process; the second, perfected by Wilson, is called the *acidification*; and the third, the modification of Tilghmann's invention, called the *high pressure* process. We will take them *seriatim*. The theory of the saponification process is based upon the fact, that glycerine has less affinity for the acids than an alkaline base. Accordingly, if the fat be heated with lime or soda, the glycerine is set free, and a *soap* is formed. If soda be used, the soap is soluble, and, as such, is the ordinary vehicle for removing dirt. But where lime is employed, an insoluble soap is formed. This is the plan adopted for the manufacture of stearine by Chevreul's process. Into a large lead-lined tank, certain proportions of tallow and palm oil are emptied from the original tubs, which are finally steamed. Thereupon a certain amount of slaked lime, varying in quantity with the nature of the fat used, is added, and the whole boiled for some hours with open steam. At the end of the time, the tallow of the acids will have combined with the lime to form a hard substance, technically known as "rock;" chemically, as a mixture of stearate, palmitate, and oleate of lime. The liquid contains the glycerine highly diluted, and is known as "sweet water." The rock is then removed to another lead-lined tank, where it is boiled with strong sulphuric acid. This combines rapidly with the lime to form insoluble sulphate, and the freed acids float on the top. When partially cool, they are run into flat pans, and allowed to solidify. The cakes are placed in horsehair bags, and introduced into the hydraulic press. Here they undergo a pressure at a gentle heat, sufficient to force out the bulk of oleic acid; by this time the cake has assumed a light yellow colour, instead of the original dark brown. The oleic acid still contains much stearine, which is removed by various processes, still the subject of much inventive energy, as the relative prices of stearine and olein being as 50—30, the success or failure of a factory often depends upon the percentage of stearine obtained.

The cakes are now placed in stronger bags, and subjected to a considerably higher pressure, approaching six tons on the inch, at a temperature of over 120° Fahr. Cast into blocks, they are then ready for the manufacturer. The stearine obtained by this process, is beautifully crystalline. It is a mixture of stearic acid and palmitic acid, often called margaric* acid. It is still open to doubt whether margaric acid is a true compound, or simply an alloy of the two other acids. The reasons for believing it to be an independent compound are, that its formula, $C_{17}H_{34}O_2$, is intermediate between those of stearic acid, $C_{18}H_{36}O_2$, and palmitic acid, $C_{16}H_{32}O_2$.

Chevreul first called the fatty acids he discovered margaric and margarous, the latter being stearic acid. Heinty has shown the margaric acid of Chevreul to consist of 90 per cent. palmitic, and 10 per cent. stearic acids. All other saponified margaric acids, so called, have been proved to be different mixtures of stearic, oleic and palmitic acids. But an actual margaric acid, of the formula $C_{17}H_{34}O_2$, may be obtained by the action of water on cyanide of cetyl—

$$C_{17}H_{33}N + 2H_2O = C_{17}H_{34}O_2 + NH_3.$$

This is a yellowish body, crystallizing in fine needles. By re-crystallization, and partial precipitation, the margaric acid may be made to yield a higher member still, $C_{19}H_{38}O_2$, which has not, I believe, been found in natural products hitherto. The name margarine is, however, too tempting not to be applied, in a good many modulations, to candles of pearly lustre by the makers.

One of the great obstacles to commercial success in the manufacturing of stearine was the difficulty of the disposing of the oil, which was a waste product, and would have remained so, but for the wise step of removing the duty on soap. It is now, however, almost as important as the stearic acid, being employed for making what is known as pure oil soap, an article in immense demand among dyers and bleachers.

The next process—that of acidification—requires a short history, by way of preface. Till now, only tallow had been employed for making stearine, though, in 1836, Messrs. Hempell and Blundell took out a patent for making candles from saponified palm oil. These, as you see by this specimen, give a fair light, but are dark in colour and are greasy to handle, and never became popular. In 1829, Mr. Soames had taken out a patent for pressing cocoanut oil, obtaining a solid and a liquid. This cocoanut stearine was a decided improvement upon pressed tallow, but the candles made from it still required snuffing, and consequently were never extensively used. The composition of cocoanut oil, as already shown (Lecture III.), differs very considerably from that of palm oil and tallow; the proportion of glycerine is comparatively small, and the fatty acids very numerous; some of them, as *caproic* and *caprylic*, are volatile at low temperatures and give very pungent vapours, especially when the candle is blown out, which, of course, tended to render this candle objectionable. It was not till Mr. Wilson brought out his composite candle, which I have already described,

* *Margarita*, a pearl.

composed of the cocoanut stearine and the new stearic acid, that they became popular. Their sale is still very great, though the composition of the present composite candle differs materially from those first introduced under that name. In 1840, Mr. Gwynne patented a process of distillation *in vacuo* for fatty bodies, and also for distilling fatty acids, under atmospheric pressure. Though the principle was mainly the exclusion of air from the apparatus and was valuable, the working was not found practicable. In 1842, Messrs. Price and Co.—under the name of W. C. Jones—patented the process of distillation of acids from cocoanut oil alone, and also after combination with lime. Very beautiful candles were made by this method, but were still subject to the same complaint of those of stearine, namely, of evolving vapours. The candles made of the product of distillation from the cocoanut lime soap were free from all defects, but their cost was far too great. Various experiments were tried, and patents taken out; but we cannot stop to consider any till we reach the patent of Messrs. Wilson and Gwynne, in 1843, which embodied the suggestion of M. Frémy, to heat oils with acid instead of alkali; only, instead of following his recommendation that the vessel should be kept as *cool* as possible, the patentees recommended a high temperature, and distillation under superheated steam. The process will be best understood from the actual description. Tallow oil is subjected to the action of strong sulphuric acid at a very high temperature, in the proportion of 6 tons of the oil to 7 cwt. of acid. By this means the glycerine is converted into sulpho-glyceric acid, with evolution of sulphurous acid, and a certain amount of carbon. After the acid treatment, the black mass in the vessel looks anything but promising. A little washing, however, frees it from the residual charcoal and acid, and it is then transferred into a still, into which superheated steam plays, and this, with the aid of gentle "bottom heat," distils over the acid. Here is the raw palm oil of a golden-yellow colour. Here the black mass produced by the acid treatment, and this firm white substance the product of distillation. In the still a black thick pitch remains, known commercially as palm pitch. What has come over is pure palmitic acid. The medium runnings of the distillate are the best. The first and last are not so good, and are used for inferior candles. From this palmitic acid the finest composite candles are now made. Price and Co. subject their distillate to hot pressure, and obtain the "Belmont Sperm" thereby. You will remark the beauty of their appearance, and the clear lustre of the flame. I have here burning, side by side, a candle of tallow, and a candle of stearic acid, with equal wicks, and you will perceive at once the difference made by the exclusion of the glycerine. I have forgotted to mention, in the description of the palm oil, the kernel of the nut, from which is obtained a very large amount of oil, equal to, if not exceeding, the quantity produced from the fruit. The composition, however, is quite different, being, in fact, almost identical with that of cocoanut oil, which it replaces in many instances, especially in the manufacture of soap, for which both these oils are abundantly employed. So much for the saponification and distillation processes. Mr. Tilghmann, in 1854, took out a patent for the separation of fats into acids and glycerine by heating with water under pressure. He suggested pumping the mixture of fat and water through a coil heated to a temperature exceeding 800° Fahr., and at a pressure of 2000 lbs. to the inch. Messrs. Wilson and Payne patented a method by which superheated steam passed into the fat at ordinary pressure effected the separation, and distilled both acids and glycerine. By resubjecting the latter to this process, Mr. Wilson obtained the beautiful glycerine for which Price's Patent Candle Co. have so high and just a reputation. I cannot dilate as I should like to upon the uses and beauties of this beautiful alcohol. They form part of that branch of chemistry known as saponification, a wide reaching and deeply interesting subject. However, Mr. Tilghmann's idea has been amplified, and on the Continent a great part of the stearine is made by what is called the autoclave process. The tallow and palm oil are introduced into a stout copper vessel provided with a stirrer, into which superheated steam is passed till the pressure reaches 250 lb. on the inch. After several hours' agitation at this pressure, the separation is complete. Each of these methods has its particular advantages, and is applied to certain specialities of stearine, in the choice of which experience is the only guide. I have on the table samples of candles produced by all the methods I have named, and many more (which will be particularized in the last lecture on candles). I cannot conclude witnout drawing your attention to the great results which have followed the discoveries of Chevreul and Wilson. Had it not been shown that by these processes the worst and darkest greases can be forced to yield a clean and beautiful substance, palm oil would have been almost useless to the candle-maker. As it is, over 40,000 tons are imported annually into England, and, no doubt, far more into the Continent and America. The kings of the countries where the palm tree grows find that the labour of their subjects, in collecting the fruit and extracting the oil, is far more remunerative to them than the selling of these subjects into slavery. Being as keenly alive to their own interests as any white men can be, they have become humane as a matter of business. By encouraging the influx of European goods in exchange for their native productions, they have brought about their own civilization far more rapidly than could have been effected by the simple spiritual pressure of missionaries unendorsed by self-interest. There are many other varieties of tree oils, such as the Cahoun palm, the Bassia butter, and others of which I have already given the names and compositions, and of which you see specimens on the table. We must now dismiss the vegetable and animal kingdoms, and devote the next lecture to the consideration of those products of a bygone world—paraffin and petroleum.

Those for whom the history of the stearine industry possesses sufficient interest would do well to read Mr. G. F. Wilson's excellent lecture on the subject, delivered before the Society of Arts, in 1852, and a paper read a short time subsequently, in amplification of the lecture. For the major portion of the above information I am indebted to these records, written by one who should, perhaps, rank next to Chevreul for the share he has taken in promoting this gigantic industry.—L. F.

Addendum to Lecture II.

Since the publication of Lecture II., Professor Thiselton Dyer has kindly called my attention to several points where my statements concerning the waxes need emendation; I therefore add the following particulars:—

Chinese Wax (*Chung-peh-la*).—This wax had not assumed commercial importance in China till the thirteenth century, and, till a much later date, was used only by those of the highest rank. The cultivation of the insect is now an industry next to silk in importance. The annual value of the amount produced is computed at about £600,000. Concerning the name and the nature of the insect which produces the wax, and the tree on which it grazes, there has been much doubt. This is partly due to the fact that several other species of *Coccus* produce kindred but dissimilar substances. Thus, the *Coccus ceriferus* produces a substance called white lac, a brittle semi-transparent body, with appearance and properties by no means resembling *peh-la*. Mr. Lockhart, of Shanghai, has given much information concerning this insect, and Mr. Westwood reported upon the specimens of insects sent over by him, and proposed the name of *Coccus sinensis* for the new insect. The form of the *coccus* is not unlike that of the small wood-louse. The young are probably the real producers of the wax. As regards the nature of the tree upon which the insect feeds, and the branches of which it encrusts with wax, the statements are also conflicting. From a Chinese drawing with names appended, we may judge the tree to be of the species *Ligustrum lucidum*, although another drawing, as pointed out to me by Professor Dyer, would show that the insect also affects the *Fraxinus Chinensis*, or China ash. In my second lecture, you may remember, I quoted *Rhus succedanea* as the most likely forage, inasmuch as that tree yields Japanese wax, but to this Professor Dyer objects the dissimilarity of constitution between the Chinese and Japanese wax, the latter of which you will remember is a palmitate of glycerine; the former was cerylic cerotate. But as the acids are of the same series, and Professor Maskelyne has obtained palmitic acid by the saponification of Chinese wax, I ventured to think that the predetermination of the plant to form wax might be carried out differently in the insect to the fruit. But as it is very doubtful whether the insect feeds at all upon the *Rhus succedanea*, my theory must be received with extreme caution. Professor Maskelyne's paper, which gives the most comprehensive account of the chemistry of *peh-la*, is to be found in the *Quarterly Journal of the Chemical Society*, vol. v., p. 24. Sir Benjamin Brodie ('Transactions of the Royal Society,' 1848, p. 159) also gives an account of its composition. In the Museum of the Pharmaceutical Society there is a twig of the *Fraxinus Chinensis* coated with the wax of this insect, and Mr. Westwood's description is published in the *Gardeners' Chronicle*, July 30, 1853. Mr. Fortune obtained a plant through some Catholic missionaries from the province of Sze-tchuen, which has much similarity to some species of *Fraxinus*; and in Hanbury's 'Science Papers,' at pp. 60 and 275, will be found a copious account, containing nearly all that is known concerning this insect, with woodcuts, etc. Concerning the Japanese wax, Professor Dyer informs me that it is not produced from the *root*, as I stated, but from the *fruit* of the *Rhus succedanea*; and in the North of Japan, from the berries of the varnish tree, *Rhus vernicifera*. It must be observed that the varnish is not made from the wax. The latter is yielded by the berries on boiling, to which process they are subjected several times, with pressure in bags, a small amount of oil having been added to render the wax more fusible. The varnish flows from incisions made in the stems of this species of *Rhus*. Both these trees, and several other wax producers, are in the Kew Botanical Gardens.

It will be observed that I have not mentioned the properties of the whale, seal, and other oils of that species (manatee, dugong), etc. Mr. A. H. Allen, on the evening of my third lecture, read a paper before the Society of Chemical Industry* upon these oils, in which he points out that they contain a large proportion of free oleic acid, and suggests that to the presence of this a great deal of the clogging of machinery lubricated therewith is due. He also thinks that sperm oil should, from its constitution, like sperm itself, be classed rather with the waxes than with true oils; and the bottle-nosed whale oil closely resembles that of the cachalot. As regards the oil from both these whales, Mr. Allen endorses my statement that it produces sperm from whatever part of the body it be taken. He attributes the differences of properties in the two oils, as commercially known, to the fact that while the sperm oil is boiled down on the ship, and hence freed from the fibre soon after death, the bottle-nose oil has been prepared from boiling the blubber after it has arrived in England, when it has undergone putrefaction to a more or less considerable extent. The northern and southern whale oils he regards as triglycerides. One important difference between the whale and sperm oils lies in their specific gravity; that of the whale being ·880, and that of the sperm ·914, which would strengthen the presumption of the waxy nature of the latter. Two oils known in the market as shark-liver oil, and African fish-oil, are of very light density, and Mr. Allen expects that they will prove to resemble sperm oil in constitution; but hitherto they have resisted all attempts at saponification. His paper is full of interest, and, containing information almost entirely novel, is well worthy of study by those interested in the subject.

Parliamentary and Law Proceedings.

Prosecutions under the Sale of Food and Drugs Act.

At the Marylebone Police Court on Wednesday, August 15, before Mr. A. De Rutzen, stipendiary magistrate, Mr. Joseph John William Allen, chemist and druggist, of 19, Elizabeth Terrace, St. John's, Hampstead, and Mrs. Jane Allchin, of 1A, Elizabeth Terrace, St. John's, Hampstead, were charged on two summonses under the Sale of Food and Drugs Act, that they did unlawfully sell to the prejudice of George Allan Smith, Inspector of the Parish of St. John, Hampstead, certain drugs, to wit:—(1) 3 ounces of tincture of quinine, B.P., which was not of the nature, substance, and quality of the article demanded by the purchaser, inasmuch as it did not contain the proper quantity of sulphate of quinine, viz., 8 grains to the ounce, contrary to the statute in such case made and provided. (2) 6 ounces of spirits of nitrous ether, B.P., which was not of the nature, substance, and quality of the article demanded by the purchaser, inasmuch as it did not contain the proper quantity, viz., 2 per cent. of nitrous ether, contrary to the statute in such case made and provided.

Mr. S. J. Porter, of the firm of Messrs. Glaisyer and Porter, Solicitors, Birmingham, acting under the instructions of the Secretary of the Chemists and Druggists' Trade Association of Great Britain, appeared for the defendants, and Mr. Ricketts represented the parish authorities.

Mr. Porter asked to be allowed to mention the cases of Allen and Allchin, and said that summonses had been issued against them under the Sale of Food and Drugs Act, and stood some distance down the charge sheet. He wished to apply for an adjournment, and based his application on the fact that the summonses were not served until the previous Friday, and that, therefore, sufficient time had not elapsed to allow of an independent analysis being made of the samples of drugs left with one of the defendants by the inspector.

Mr. Ricketts said that in addition to the summonses mentioned by his friend, a fifth summons had been issued under the same Act against Mr. Pipe, a chemist and druggist, residing in King's College Road. Although he had no objection to an adjournment of the whole of the cases, he saw some difficulty in allowing one case to proceed and the others to stand over, more particularly as Mr. Pipe was charged with selling indifferent spirits of nitre, and two of the other summonses related to the same drug.

Mr. Pipe expressed a wish that his case might be taken at once, but subsequently decided to have it adjourned with the others, and it was finally arranged that the hearing of all the summonses should be taken on September 12.

Mr. Porter then said in the case of Allen he had to ask that the magistrate would be good enough to make an order that sealed samples of the drug purchased from the defendant be handed to him for independent analysis.

The magistrate inquired how it was that the inspector did not leave sealed samples with Mr. Allen at the time the purchase was made.

Mr. Porter said that the inspector had carried out the requirements of the Act by asking Mr. Allen at the time the purchase was effected if he would have sealed samples, but Mr. Allen unfortunately said that he did not care about them, and under the circumstances he should feel obliged if the magistrate would make the order for which he had applied, as he presumed the sealed samples would still be in the hands of the inspector, and it was important that an independent analysis should be made.

Mr. Ricketts said that he opposed the application entirely; it was admitted by his friend that the inspector had done his duty in offering samples to Mr. Allen, and when the case was heard the defence would have an opportunity of cross-examining the public analyst, and if, after that, they were not satisfied with his analysis there was a provision in the Act by which the sealed samples could be analysed by the Somerset House authorities. He certainly could not agree to the samples leaving the inspector's hands at that stage.

Mr. Porter said that he did not wish that the whole of the samples left by the inspector should be given up, but that they should be further divided, still leaving a portion with the inspector which might subsequently go to Somerset House if necessary.

The magistrate said that he really did not feel disposed to make an order at that stage of the proceedings.

Mr. Porter then asked that the sample in the inspector's hands might be at once transmitted to Somerset House.

Mr. Ricketts said he thought the application was somewhat premature.

Mr. Porter said his object in making it was to save a probable further adjournment at the hearing.

Mr. Ricketts said if the other side made an application for a further adjournment at the hearing, and his worship thought it was a reasonable application, he, on the part of the authorities, would raise no objection.

Mr. Porter said that after what Mr. Ricketts had just said, he would withdraw his application for the order.

Poisoning by Morphia.—A Mistaken Diagnosis.

A few months ago in a northern university town a medical man of some professional standing read a paper before a local society on what he described as a case of poisoning by salicylate of soda. The patient, a young man, aged twenty-nine, had for some days been suffering from pains in his joints, which he thought were rheumatic. One morning on trying to get up, he complained of a pain in his side, and was compelled to return to bed. His wife sent to a neighbouring druggist for half a dozen 15-grain salicylate of soda powders, which she had been told were good for rheumatism. The patient was given one of these powders, and in an hour and a half fell asleep. After sleeping for two hours he was roused up and had some dinner, but feeling very drowsy went back to bed and was soon asleep again. His wife tried to waken him three hours later, but failed to do so, and sent for a doctor, who came in about an hour, and found him comatose with stertorous breathing. The pupils were contracted and not sensitive to light, the face, neck, and ears were covered with perspiration, and the extremities cold and clammy. The treatment was very simple, consisting of mustard to the back of the neck, heat to the trunk and legs, and ice to the head. The patient was seen again three hours later, when the pulse was noted to be 100. At one o'clock the next morning the pulse was 130, and the breathing laboured. Death occurred that afternoon at half-past two, sixteen hours and a half after the powder had been taken. A *post-mortem* examination was made, but seems to have thrown very little light on the subject. The five remaining powders were examined, and, as they gave a violet colour with a solution of perchloride of iron, were declared "to consist wholly of salicylate of soda." It was stated, however, that salicylate of soda could not be detected in the viscera or in the blood, and the urine was not tested. In the discussion which followed the reading of the paper, doubts seem to have been expressed by several gentlemen present, one member suggesting that it was acute congestion of the lungs, whilst several thought that it was not a case of poisoning at all. The President, with a foresight which does him credit, gave it as his opinion that the powders consisted of morphia, with a small quantity of salicylate of soda as an impurity. The matter would probably have remained for ever in doubt had not the widow brought an action against the druggist for £750 damages as compensation for the loss of her husband. The court ordered one of the powders to be sent to Dr. Stevenson Macadam, of Edinburgh, for analysis. From his report, just received, we learn that it contained 49·6 per cent. of morphia, equal to 52·63 per cent. of muriate of morphia! This, then, effectually disposes of what was supposed to be a very remarkable case of poisoning by salicylate of soda. We may mention incidentally that the case was compromised for £400, the druggist having succeeded in showing that he sold the drug just as he purchased it from an eminently respectable firm of wholesale dealers. There is no reason, as far as we know, to suspect anything but carelessness as the cause of this admixture. But it was carelessness of a very coarse character. It is to be regretted that in the public interest the whole course of the drug and its supply was not traced. Next to the lesson of the necessity for a little more hesitation in diagnosis, and a little more thoroughness in investigation, is the lesson taught by this case as to the insufficiency of legal investigations of this kind in Scotland. Such facts as obtained in this case would scarcely have eluded exposure under the jury system of England led by a medical coroner.—*The Lancet.*

Prosecution under the Apothecaries Act.

At the Southwark County Court, on Friday, August 3, before Mr. Holroyd, Judge, an action was brought by the Medical Defence Association in the name and with the consent of the Apothecaries' Company to recover £20 penalty against the defendant, Charles Pearson, a chemist carrying on business at 104, Stamford Street (and who is also district registrar of births and deaths), for acting as an apothecary without legal qualification. Mr. H. R. Hodson, barrister, instructed by Mr. C. J. C. Pridham, solicitor to the Medical Defence Association, appeared for the plaintiff society, and Mr. Washington, solicitor, of the firm of Messrs. Hicklin and Washington, for the defendant. Several technical objections by Mr. Washington on behalf of the defendant having been overruled by the learned judge, Mr. Hodson stated the case for the plaintiffs and called witnesses in support. From their evidence it appeared that the defendant was in the habit of making his daily rounds as a medical man, attending the sick at the bedside, sounding the chest, feeling the pulse, etc., and after his visits forwarding medicine of his own selection for their cure or relief. The defendant in his defence relied on the 28th section of the Apothecaries Act, contending that he had done nothing which exceeded the rights and privileges reserved to chemists by the section, and that chemists had always the right to prescribe in simple cases. He also relied on the fact that he was "a perpetual student" of Westminster Hospital, and attended the cases referred to in the plaintiffs' evidence at the bedside for the sake af acquiring experience.

The learned Judge found that the evidence proved that the defendant in the cases relied on by the plaintiff society had acted as an apothecary and not as a chemist. There would therefore be judgment for the plaintiffs for the amount claimed, £20, together with costs on the higher scale, as the issues involved were of public interest.—*The Lancet.*

Correspondence.

Brief Note on Calisaya Ledgeriana.

Sir,—I think it will tend to the enlightenment of your readers if I state at once what is my contention in the Calisaya controversy to which you have directed their attention. It is simply this, that Mr. C. Ledger's "*Ledgeriana*" is a legitimate Calisaya, and not a new species. Of much less importance are the observations I have made as to Dr. Trimen's plates and description of the plant figured in the *Journal of Botany*. These are entirely superseded by Mr. Moens' own description and definition of the *Cinchona Ledgeriana*, Moens, in a very valuable work 'De Kina Cultuur in Azie,' which, through the courtesy of this gentleman, I have just received; and to which, in the conclusion, I shall again refer.

I have always understood that by an unwritten law of botanical science the privilege of naming a plant belongs to the botanist who first observes and properly describes it; always supposing that he has regard to what has previously been known about the subject. This rule, which common sense appears to sanction, is in danger of being disregarded in India.

The name and history of Calisaya bark has engaged much of my attention in the last few weeks; as I have availed myself of a visit of Mr. C. Ledger to this country (on his way to Australia) to re-investigate the whole question, which it was my pleasure to study many years ago with my lamented friend Dr. Weddell.

The 'Histoire'* of this distinguished naturalist is a treasury of really scientific investigation. It is not, however, by any means exhaustive; as in his first voyage he did not observe the best kind of his *C. Calisaya*. In his second journey† to the gold districts of Bolivia, he obtained specimens from the Yungas and from Larecaja of the bark of the finer sorts which are now in question. In his subsequent notes, 'Sur les Quinquinas,' he further describes these.‡

Dr. Weddell did not invent the term Calisaya, but adopted it as the term generally in use. He says that it was indiscriminately called Colisaya, Calisaya and Culisaya. Further§:—"It is to this species that we owe the most precious of all the barks employed in the healing art,|| that which has always been known in commerce as the Quinquina-Calisaya, and of which the origin had remained completely unknown in a botanical sense."

I have in fact a fine specimen¶ (which I bought with the rest of Pavon's barks) called *Quina de Calisaya* (ascribed by that botanist to *C. lanceolata*, a very different bark). It is of Weddell's *a vera* quality.

Dr. Weddell proceeds thus:—

"In spite of the different explanations which authors have given, the etymology of the word "Calisaya" is still very obscure. M. Humboldt thought it came from the name of the province from whence it was first derived; but well-informed persons have assured me that such a province never existed. In the department of La Paz, where it is found abundantly, it still most frequently bears the name of Colisaya or Calisaya; and I am disposed to think that these designations have been applied to it on account of the red colour which the external face of the bark presents when drying, or probably (*bien*) of that which its leaves have sometimes. *Colli* means really *red* in the Quichua language, and *saya*, taken in a figurate sense means sort or form. The red maize is called *colli*, çara, or *culli* abbreviated.

Weddell lived some time amongst the Indians and studied their language,** which seems to have some elements of affinity to the Sanscrit. After consulting Tschudi's dictionary, I have no doubt that Dr. W. is right, and that it means "the red sort." Mr. Ledger says the word means "red" in Aymara as well as in Quichua.

Now it is exactly this red sort, called in Spanish, *rojo*, of which Mr. Ledger has always been in search, hearing of its superior qualities from the Indians. Mr. Ledger tells me that Dr. Weddell sought for the white flowers, which are distinctive,* but without success. Mr. L. endeavoured to assist Dr. W., but it is easy to understand, in conversation with him, the difficulties which beset the path of inquiry. Mr. L.'s explanation of the term *rojo* is, that the leaves turn this colour whilst the tree is flowering, changing to a dark purple before they fall.

The trees under these circumstances present a magnificent appearance, visited by multitudes of humming birds and bees, and the older ones adorned with the beautiful cryptogam, *Hypochnus rubrocinctus*† (Ehrenb.). The presence of this used to be considered in trade as indicative of the best kind of Calisaya. Specimens so found in my possession date from 1853.

This description especially applies to the finest and most luxuriant trees, which probably raise their heads above the surrounding forests, and present their white flowers, fraught with pollen of superior power for cross fertillization, to the access of the useful visitors above named; also perhaps to more frequent damage by frost.

The Indians call them "tata" (father) trees, and believe they are so important to the rest that where they are found all the bark around will be Colli-saya; and they cross themselves when they meet with them. They think that without them all would perish.

Dr. Weddell says of his first sort "*C. vera*," "The variety which I havs been describing is the most frequent. It bears in Bolivia the name of *Colisaya amarilla*, *C. dorada* or *C. anaranjada*."

That is to say the *Cinchona Calisaya vera* described and figured as such by Sir Joseph Hooker, in *Curtis's Bot. Mag.*, from a tree at that time (1879) flowering in my possession. This tree, which is still so flourishing that I have difficulty in keeping it within the narrow compass of my stoves, represents probably very fairly this sort then very abundant, now practically extinct, but in one district extensively replanted, owing to advice given by Mr. Ledger some twenty years ago.‡ Mr. Ledger does not recognize my tree, owing to its large leaves, but approves some of my young plants of *Ledgeriana* from the Yarrow Estate, Ceylon, and also in part those from Mr. Thomas Christy's seed from South America. All these belong to the next division of Weddell and the bronzed appearances of the young tips which summer has brought on my young plants, and which is much rested on in Ceylon, may be looked upon as a ready mode of discrimination of the second sort from the *a. vera*. The rich velvety appearance and ciliated margin of the young leaves are also useful to this end.

I proceed with Dr. Weddell's description of this second variety.

"Another sort of bark remarkable for the dark shade of its external face, which is often wholly of a vinous black, bears the names of *Calisaya zamba*, *C. negra* or *C. macha*. I have remarked it particularly at Apolobamba in Bolivia, and in the province of Carabaya in Peru."

He did not then describe this further, but I have from him an excellent specimen of flat bark, marked *Calisaya zamba*, gathered at that time, and I learned from the same source how to distinguish this superior quality.

In 1869 he describes it more fully§ (see the original) and adds:—"I brought this variety of Calisaya in 1851 from

* Paris, 1849.

|| 'La therapeutique.'

¶ Dating probably from last century.

** 'Voyage dans le Nord de Bolivia,' p. 555, Weddell, 1853.

* It seems impossible to overcome the jealousy of the Indians about these trees and it is easy to understand that it is a work of difficulty to get even sight of the flowers, unless when the tree is cut down. Mr. Ledger assures me that he has seen pinkish flowers on one tree, of which the flowers were white towards the summit. Dr. Weddell related to me that on one occasion he had to fell three trees in order to bring to the ground one (of I know not of what sort) whose flowers he wished to observe.

† Figured by Fée 'Sur les Cryptogrames,' Tab. v.; also by Goebel, *Pharm. Waarenkunde*, Taf. xv.

‡ I have specimens of the bark from 1849 downwards. That which is now imposed upon the public as flat Calisaya bark, judging from a specimen given me by Mr. Lescher (who has exposed this fraud) is *Cochabamba* bark, according to Ledger, or *C. Australis*.

§ *Annales des Sciences Nat.*, T. xi., 347, xii., 54.

the mountains which rise above the river of Coroico, an affluent of the Mapiri, one of the most important in the department of La Paz. The cascarilleros of the country have pointed it out to me as giving a bark superior in quality to that of other varieties growing in the same places, and I confess that I have been happy to see this appreciation of the native (l'homme des bois) confirmed by Mr. Howard. It is, in effect, from a bark recognized by him as identical with that which I have described that my eminent friend has obtained the largest proportion of quinine which has yet been found in a Quinquina, that is to say about double the quantity which MM. Delondre and Bouchardat indicate as the average yield of the Calisaya. The shade, more or less purple, of the under part of the leaves gives to this variety a character of resemblance to the *C. Boliviana*.* I have not seen its young leaves, but it appears to me that they must have much analogy with those of the variety which I have just named. Perhaps we may also consider as giving a representation of it the figure 2 of the plate which accompanies the article published by Mr. Howard on the barks brought from Bolivia by the merchant Don Pedro Rada" (*Journal of Botany*, January, 1869). This plate was coloured in accordance with some plants derived from Mr. Ledger's seed, then in my possession.

Now all this description of the *Zamba* and of Rada's *Negrilla* agrees entirely with Mr. Ledger's *rojo*. He at once recognizes Weddell's specimens and mine as such, notwithstanding the vast distances between the different habitats.

Mr. Ledger wrote me,† "The seed sent by me in 1865, 'Calisaya red bark,' is not (as you say) the *morada* of the Spaniards; it was the *rojo*."

When I examined this bag of seeds I pointed out that it belonged to *var. microcarpa* of Weddell, and was consequently of good quality. It was not, however, all *rojo*. This is proved by the germination of the seeds in Java, for out of some six or eight varieties obtained, only one is acknowledged by Mr. Ledger as his true *rojo*. This is figured in plate IV. of my 'Quinology.'

It is comparatively scarce. In the same letter he writes, "I always understood the red bark, Collisaya, to be the best of all in its yield of quinine. For one tree of the *rojo* you will find fifty of the Calisaya. The leaves of the *rojo* are of a bright scarlet colour, and of darker green on surface than those of other good descriptions."

This richer green colouring of the leaves, changing very naturally to bright red in decay, is much rested on by Mr. Ledger, and I have no doubt finds its explanation in the term *macho*, which Dr. Weddell applies to this sort, *Colisaya zamba*, *C. negra* or *C. macha*.‡ The two first imply the very dark colour of the upper side of the slabs of bark, which are now rarely, if ever, seen; and these terms are probably forgotten and quite unknown to Mr. Ledger, though not to Rada, who called his fine slabs, the like of which have never been seen since, *negrilla*. I am sorry to hear that Mr. Rada has suffered so much in health, partly from wounds received from the wild Indians on his voyage down the rivers, that he is not likely to undertake another such expedition. The trees from which these were taken were from 120 to 150 feet in height.

I now come to the term *macho*,§ which Dr. Weddell explains thus:—"The flowers of the Cinchona present in the relative greatness of their sexual organs variations very interesting to study—not only on account of the frequency with which they present themselves in many species, but by the curious circumstances which (parfois) accompany them. If the stigmata are protruded the anthers are almost sessile in the middle of the tube of the corolla; if, on the contrary, the anthers raised on their filaments appear at the mouth of this tube, the style then is found reduced and the stigmata occupy the place before held by the anthers. In a word the development of the style and that of the stamens are constantly in the inverse proportion the one to the other; and not only that of the male organs is always accompanied by the simultaneous development of the floral envelopes, but, a fact very worthy of remark, other parts of the plant appear to feel this predominance of the strong sex. The leaves, for example, may be more richly coloured, the bark more robust. Now, the cascarilleros, who very certainly never occupy themselves with the details of the flowers, have, nevertheless, remarked in the aspect, in the produce even, of these* bark trees such differences, that they have had the idea of distinguishing them by the epithets, male and female (*macho y hembra*), and since my attention has been awakened to this subject, I have been not a little surprised to find a coincidence between this epithet of *macho*, so naïvely applied by the natives (les hommes des bois), and the predominance of the male system of which I speak."

I think I now see the reason why Dr. Weddell did not proceed in the description of this variety. He found it, indeed, "un peu embarassante," to make a distinct variety, still more a species out of the *macho*. To distinguish thus, the bull amongst the herd might appear pedantic!

Weddell's 'Histoire' was published in 1849. When afterwards, in 1869, he saw his way clear to define his *C. calisaya microcarpa*, he gives a description intended (?) to include† all the forms of small fruited Calisaya, at all events the zamba and zambita (he drops the term macho). The pubescency of the under surface of the leaf seems more marked in Weddell's plate than elsewhere and he does not give (as not having seen) the flowers, but it seems to me that not only Mr. Ledger's *rojo*, but all that might imperfectly be called Colli-saya, the *verde* of Mr. Christy,‡ the *C. Boliviana* and other forms may all be called Weddell's "second sort." I do not know the form which he defines "*subtus pubescentibus*;" this, strictly speaking, excludes all the other forms.

My publication of *C. Calisaya*, var. *Ledgeriana*, is too inclusive, as taking in all the varieties recognized as such by Mr. Moens. I am sure that this gentleman, to whom we are all so much indebted for his able analyses, and I myself specially for his most carefully prepared herbarium, will see that it belongs to Mr. Ledger, and to him alone, to define what is the true *Ledgeriana*. It is then my form A, the *macho*, exclusive of form B and form C and other forms now existing in Java and in Ceylon, from whence specimens (received from T. N. Christie, Ceylon), are now in the Museum.§ They are (?) *microcarpa*, but not *Ledgeriana*.

The bark of the true *Ledgeriana* is that which was sent me by M. Van Gorkom; typically resembling Weddell's *zambita*, from the province of Yungas, now before me. Of this extraordinarily rich bark a certain portion has come in trade, but probably a larger portion, from very inferior trees (still called *Ledgeriana*). The recent specimens from the Amsterdam Exhibition, now in the Pharmaceutical Society's Museum are miserable; but I have taken care to forward a true specimen. It will be seen at once how much these differ. I have not met with any yet, from British India, of the true *rojo*.

I also ask the Pharmaceutical Society's acceptance of original specimens from the herbarium of Mr. Moens, of the form A, from which my plate of the true Ledgeriana was drawn;—and also of other forms.

Mr. Ledger does not recognize my *Micrantha calisayoides*, nor Dr. Trimen's *C. Ledgeriana*, Moens. As we have no description of the bark of the latter, nor any analysis as far as I can learn of the bark of the tree itself, I may be mistaken in associating the two; for the rapid degeneracy of sorts when, in cultivation, the beautiful natural arrangements are interfered with, begins to open a new chapter in the history of the culture; which it would scarcely be pleasant, though perhaps necessary, to write; and hybridism leads to endless confusion. The pollen of the Bolivian *micrantha* may have affected some of these sorts.

I do not agree with Dr. Otto Kuntze in regarding

* This is very remarkable in the *morada* and the *Rubra venada* of Mr. Christy.

‡ 'Histoire,' p. 35.

§ 'Histoire,' p. 21.

* Mr. Ledger says "they judge of the good *rojo* slabs by their relative greater weight. The relative weight and thickness of bark are alike characteristic of true *Ledgeriana*. I well remember purchasing and packing, in 1852, more than 120 tons of *Calisaya vera* bark. Out of all that quantity I was only able to pick out 2 tons of *rojo* or *morada* slabs. You also can verify my statement by your own practical knowledge."

† *Annales der Sciences Nat.*, vol. xi., p. 5.

‡ A distinct and very valuable form, Weddell's *C. Calisaya oblongifolia* (see *Sciences Nat.*, ([5], t. xii., p. 5).

§ See *Pharm Journ.*, August 11, 1883.

hybridism as the source of improvement (quite the contrary), but he has perhaps done good service in pointing attention to the subject of cross-fertilization.

I look upon the *Ledgeriana*, not as a species, but as one form of Dr. Weddell's second division of the species, and as being the Calisaya *par excellence*, the true red sort.

I have been surprised with the high appreciation by Mr. Ledger (and as he tells me by his Indian servant) of my plate of *Calisaya anglica*. The leaves and flowers are both too large for *Ledgeriana*, but the colouring, to which I attended myself, as taken from a tree flowering with me, represents exactly (it seems) the rich appearance of the leaves.

Mr. Ledger's Indian exclaimed with admiration and delight on seeing my plate that it was *Tata, tata, tata*. I have looked back to my description of its parentage ('Quinology, p. 87) and to Mr. Broughton's letters of 1872 and find that "the seed was gathered from two trees of the same red under-leaved variety of Calisaya," and this again from Ledger's seed. The idea of its being a hybrid must be abandoned if no interference of pollen had taken place in India. The distance between the nearest districts in which the Succirubra and Calisaya are found is, in a direct line, over 1100 miles. No possibility of the interference of the pollen of these two can arise in their native habitats.

I find that I cannot conclude this notice without more reference to technical botanical description than I intended to introduce into these pages.

I present then the diagnosis of Dr. Weddell, as definitive of the true *rojo* bark of Mr. C. Ledger.

Cinchona calisaya var. *Ledgeriana* [Weddell, *pro parte* How.].* "C. foliis elliptico-oblongis vel fere oblongis, obtusis obtusissimisve, haud raro ante apicem nonnihil angustatis s. constrictis membranaceis, utrinque viridibus vel subtus pallide purpurascentibus nervis simul rubris, axillis sat distincte scrobulatis; panicula florifera ovata, corollis albis, *antheris subexertis* (saltem in specim. obviis); panicula florifera subcorymbosa, densa, capsulis ellipticis (9–12 millim. longis) puberulis."

This it will be seen by comparison is not the *A. microcarpa*, of Weddell.† It is my form A, (Plate IV.), exclusive of B and C. It is only in part the *C. Ledgeriana Moens*, since it is exclusively the *macho* form. Indeed, in other respects it does not apply to some forms which both Mr. Moens and I had considered "*Ledgeriana*." I am much pleased to see that Mr. Moens includes, amongst these, two varieties, *a Cinchonidinifera* and *β Chinidinifera*. This is an excellent step in the right direction, and worthy of Mr. Moens' fame as a chemist, thus to distinguish these forms. If I understand right, my *Calisaya Anglica* stands under the first of these. It is *Cinchonidinifera*, and my Plate IX. *Quinidinifera*. Indeed, I am ready to believe that it is very nearly related to the true *rojo* bark of Mr. Ledger, so nearly, that he at once fixes upon it as right in the general colouring and aspect; but then it is very decidedly *Hembra* and so cannot come under Weddell's diagnosis. May it not (*pace* the botanists) be as nearly related as male and female of any race of animals? ‡

Much yet remains to be put before those interested in the subject in connection with the highly important work of Mr. Moens, which I hope you will review for the benefit of your readers.§

JOHN ELIOT HOWARD.

* 'Quinology, E. I. Plantations,' p. 85.

† Mr. Moens objects rightly to the defective colouring of my plate Plate IV., which is the fault of my artist. Plate X. I took from nature.

‡ "Hybrids (?) between *Succirubra* and Ledger, found amongst Ledger seedlings, have been found to contain 10 to 12 per cent. of sulphate of quinine, so that while possessing the robustness of the one they have been blessed with the richness of the other."—"A Java Propietor," *Ceylon Observer*, July 27, 1883. I thought the Ledger's were kept select from crossing with *Succirubra* in Ceylon. Surely these plants are from *Calisaya Anglica* crossed with real *rojo*, as above.

§ Although we are aware that Mr. Moens has published such a work, we have not received a copy, and have only recently had an opportunity of seeing one accidentally in the pharmaceutical exhibition in Vienna.—ED. PHARM. JOURN.

ESTIMATION OF PHENOL.

Sir,—In a paper on the "Estimation of Phenol," by Mr. C. Thompson, printed in the Journal of August 18, I noticed a slight error. Referring to the gravimetric estimation of phenol as tribromophenol, he remarks—"This is open to one great objection, as pointed out by Koppeschaar, that since the tribromophenol melts at 91°, some of it is lost in drying at 100° C., so that it has to be dried over H_2SO_4, or else *in vacuo*, thus taking some time." The fatal objection to drying tribromophenol in the water-bath is not that it melts, but that it (or its products of decomposition) volatilizes.

Mr. Thompson refers to "the homologues of phenol, such as *creasol*," etc. It ought to be *cresol*.

D. B. DOTT.

THE ACCEPTANCE OF SEALED SAMPLES IN PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

Sir,—Kindly grant me space to once more impress on all members of the trade the absolute necessity, in their own interests, of accepting sealed samples from the inspectors appointed under the Sale of Food and Drugs Act, when offered at the time when purchases are effected, and also to carefully look over the whole of the weights and measures used for the purpose of trade, which they have in their possession and ascertain that every weight and measure bears the Government stamp.

The need of the first caution is strongly exemplified in the proceedings under the Sale of Food and Drugs Act which took place recently at the Marylebone Police Court.

The necessity for the second caution was forcibly brought under my notice some few weeks since, when a member of the trade was found to have upwards of seventy weights and measures in his possession, not one of which had been stamped as required by the Weights and Measures Act.

The Chemists and Druggists' Trade Association of Great Britain is at all times willing, indeed, I may say, anxious, to assist chemists in any legal trade difficulty that may arise. Individual traders should, however, as far as possible, take simple precautions for their own protection.

W. F. HAYDON.

"*Victim*."—We think that the necessity for the exercise of caution in such a transaction and the danger attending attempts to deal in articles concerning the quality of which the buyer is not competent to judge are generally recognized by business men. *Caveat emptor* is a very old maxim.

V. S.—Apply to the Registrar of the Royal College of Veterinary Surgeons, 10, Red Lion Square, W.C.

Nonplus.—According to 32 and 33 Vict., cap. cxvii., sect. 1, nothing contained in the first fifteen sections of the Pharmacy Act affects persons who are registered as legally qualified medical practitioners.

Minor.—Apply to the Secretary for a copy of the pamphlet entitled 'Hints to Students.'

Glasgow.—See *Pharm. Journ.*, [3], vol. x., p. 603.

G. Cormack.—Numerous papers on the subject of syrup of the phosphates have appeared in this Journal. See especially one in vol. vi. of present series, pp. 804 and 832.

T. Kitton.—Some information upon the subject will be found in the *Pharm. Journ.*, [3], vol. x., pp. 486 and 644. It is claimed, however, that the manufacture of the composition is protected by a patent, and we understand that inconvenience has followed the preparation and sale of it in several cases.

G. A. Hawdon.—We are unable to inform you whether the name is registered, or whether any claim as to priority in its use can be established.

D. Frazer.—We do not think it necessary at present to reopen the discussion, especially since the argument of your friend is very much affected by the insertion of the word "(in)," which is not in the draft Bill.

A Subscriber.—The subject is not suitable for discussion in these columns upon the basis of an *ex parte* statement. If, as you seem to imply, your employer is failing in his duty towards you the proper way would be for you or your guardian to take steps to enforce the fulfilment of the terms of the contract.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Howard, Inquirer, Eurowie, T. M. C., W. C.

INTERNATIONAL PHARMACEUTICAL EXHIBITION IN VIENNA.

(*Continued from p.* 143.)

Before proceeding to refer in detail to some of the more interesting and important objects in the exhibition it will be convenient to recapitulate briefly the divisions in which they were grouped and the arrangements for awarding distinctions to the exhibitors who might be deemed most worthy. These divisions were six in number and were as follows:—

Group I.—Scientific Instruments and Contrivances for Pharmaceutical Purposes.

Group II.—Literature of Pharmacy and the Allied Sciences.

Group III.—Apparatus and Machinery for the Manufacture of Medicinal Products.

Group IV.—Utensils and Appliances that are Necessary or Useful in carrying on the Business of a Pharmacy.

Group V.—Drugs, Chemical Products, Pharmaceutical Preparations and Wares intended for Use in Medicine:—

(A) Chemical Products.
(B) Pharmaceutical Products.
(C) Drugs.
(D) Wines, Mineral Waters, Spirits and Food Materials.
(E) Dressings and Various Articles.

Group VI.—Contributions to the History of Pharmacy, Pharmaceutical Antiquities, Historically Interesting Apparatus, Utensils, etc.

Under one or another of these groups all the objects sent for exhibition were included and the respective merits of the exhibits were adjudged by a separate committee of jurors for each group, consisting of three members for Groups I., II., III. and VI., six members for Group IV., and eighteen members for Group V. All scientific institutions, museums and Government departments and establishments were considered outside the competition for prizes, as well as any firm a partner of which might be a member of the jury. Further any exhibitor who had obtained a first prize at any of the larger international exhibitions was at liberty to stand aloof from the competition upon giving notice of a wish to that effect four days before the meeting of the jury. The prizes to be awarded were:—(1) Diplomas of Honour for the best, most excellent and most perfect productions; (2) Gold Medal Diplomas, for inventions, improvements and skilful development of objects exhibited; and (3) Silver Medal Diplomas, for the most useful contributions to pharmacy and the branches of business connected with it. All the jurors were nominated by the Executive Committee, care being exercised that as far as possible every country taking part in the exhibition should be represented. The jury for each group elected a Chairman and Secretary and the Chairmen of all the groups elected a President and a Referee. The decisions of all the group juries were to be finally settled at a closing meeting of Chairmen and then, through the President of the jury and Referee, laid before the Executive Committee for confirmation. Any group jury desiring it was entitled to the assistance of experts, who were to be nominated by the Executive Committee and were then entitled to take part in the deliberations and vote with the jury.

Notwithstanding the laudable intentions of the organizers of this exhibition that it should be international, it must be confessed that its predominant features were rather Austrian than cosmopolitan, as will be evident from the fact that out of the 317 exhibits enumerated in the Catalogue 202 belonged to the Austro-Hungarian empire. But that it did possess some international character is shown by the following list of other countries which took part in it:—Germany, France, England, Belgium, Italy, Spain, Portugal, United States, Brazil, Denmark, Switzerland, Russia, Sweden, Norway, Holland, Turkey and Roumania. Whether a broader conception by the Executive Committee of the polyglot requirements of such an undertaking in the sending out of invitations and conveyance of preliminary information would have resulted in a fuller response from these and other countries, or whether the somewhat limited internationality was an unavoidable result of a first experiment and of the locality, may fairly remain an open question; but there can be no doubt that notwithstanding any shortcomings in this respect in the exhibition just closed, the country aspiring to hold a second international pharmaceutical exhibition will have to work hard to attain the standard set up by Austria in the first one.

Group I.—*Scientific Instruments and Contrivances for Pharmaceutical Purposes.*

Exhibits from Austro-Hungary, 10; Germany, 2: total 12.

Jurors*:—Messrs. Jarmay (Budapest), Krafft (Vienna), and Schlosser (Vienna).

This group, although made up of the contributions from a smaller number of exhibitors than either of the other sections, was not the least interesting, since in it were included the objects used as aids in teaching. These were not so numerous as might have been wished, but amongst them there was an excellent collection of models of crystals, cut out of "taufstein," exhibited by the Vienna Haupt-Gremium, and a set of models of flowers and parts of flowers, large enough to be used for lecture purposes, contributed by the General Austrian Apotheker-Verein. The Vienna University authorities sent from the "Pharmacognostische Institut" some wall diagrams and some fine sections of drugs, and from the botanic gardens and museum a very fine herbarium in four fasciculi. The plants seemed to be beautifully mounted, the delicate colours being well preserved; but such collections are not particularly well suited for exhibition, and this did not seem to attract the attention it deserved, since only one bundle was untied and it had scarcely been disturbed on the fourth or fifth day, a circumstance perhaps upon which the owners might be congratulated. In this group were included also the microscopes, thermometers, barometers, areometors, and other physical instruments, as well as the finer balances. The balances shown by the local makers, so far as they could be judged by a passing inspection, seemed well suited to keep up the reputation of Vienna for this industry; those of A. Rueprecht and J. Nemetz were especially noted for their fine appearance, an impression that has since found confirmation in the award of a diploma of

* The names of the jurors are taken from the official list; but as some of the gentlemen named had not arrived in Vienna at a period later than the first meeting of the juries, and a few did not attend at all, it is evident that this list represents rather the wishes of the Executive Committee than the exact composition of the juries by which the awards were made.

honour to the former and a gold medal diploma to latter. Messrs. Verbeck and Peckholdt, of Dresden, exhibited their short-armed balances, which are constructed on a principle that is said to ensure their turning with equal delicacy with any weight between one and two hundred grams in the pan. Another advantage that is claimed for these short-armed instruments is that in using them it is not necessary to wait until an exact equilibrium of the pans has been established, since the last minor differences in weight may be ascertained by observing the position of the tongue upon the index. In two of the balances exhibited the sensibility was so arranged that a milligram placed in one of the pans should cause a deviation of $2\frac{1}{2}$ degrees, or $\frac{1}{4}$ of a degree for each milligram. A deviation of $3\frac{1}{2}$ $(=\frac{14}{4})$ of a degree would therefore represent a difference in weight of 1·4 milligram.

Group II.—*Literature of Pharmacy and the Allied Sciences.*

Exhibits from Austro-Hungary, 15; Germany, 5; France, 4; England, 2; Italy, 2; United States, 1; Spain, 1; Sweden, 1; Switzerland, 1: total 32.

Jurors: Messrs. Geissler (Dresden), Godeffroy (Vienna), and Ludwig (Vienna).

The most conspicuous contributions to this group were three excellent displays of current literature on pharmacy and the allied sciences by F. Oscar, W. Frick, and A. Hartleben, all of Vienna; the last-mentioned especially showing amongst other works a series of upwards of one hundred manuals on different manufactures in which chemical principles are involved, published by him at a comparatively low price. Some excellently illustrated botanical works, published by E. F. Koehler, of Gera, in Thuringia, were also shown. This publisher was awarded a gold medal, and Messrs. Wood and Co., of New York, who exhibited copies of 'New Remedies' and of the United States Pharmacopœia, a silver diploma. Although not making quite so attractive a show, those whom Dr. Johnson chose to consider the victims of publishers were also represented, and they have no reason to complain that the jury was insensible to their merits. A set of all the editions that have appeared of Professor Attfield's 'Manual,' enclosed in a little book-case, hung high up on the wall, but not sufficiently high to escape the jury, who showed their appreciation of the service rendered in that work to pharmaceutical education by awarding the author a gold medal diploma. A similar honour was conferred on Herr Klinger, as the editor of the 'Zeitschrift des allgemeinen österreichischen Apotheker-Vereines,' Dr. Heger, as the editor of the 'Pharmaceutische Post,' and Dr. Méhu, as the author of various works aud pamphlets and translator of Sutton's 'Volumetric Analysis' into French. M. Ferrand, editor of 'L'Union Pharmaceutique,' and Herr Graf, editor of the 'Rundschau,' were awarded silver medal diplomas, and it was probably on account of the 'Extra Pharmacopœia' exhibited by Mr. Martindale that a like award was made to him. Accompanying a curious exhibit of the literature relating to the Struve mineral water establishment, in Dresden, there was an extremely interesting document, consisting of an autograph letter in French from Berzelius, in reply to one from Dr. Joseph Ritter von Vehring, asking in the name of the Emperor of Austria as to the possibility of a perfect imitation of the Carlsbad water being prepared. The great chemist cautiously answers that if a complete analysis of the natural water could be made the imitation would be possible, but he adds that as far as his own analysis went he was unable to say that there were no substances in the water which had escaped detection.

Group III.—*Apparatus and Machinery for the Manufacture of Medicinal Products.*

Exhibits from Austro-Hungary, 11; Germany, 6; France, 2; United States, 1: total, 20.

Jurors: Messrs. Hauptfleisch (Vienna), Kohlman (Leipzig), and Winkler (Hietzing).

The objects exhibited in this group were not very numerous, neither did they present many features that were not more or less familiar to persons who had attended the exhibitions of recent years. Nevertheless the general appearance of the apparatus was very creditable, and there were several of those contrivances for boiling, evaporating and distilling that always appeal to the weak side of the pharmacist who makes his own preparations. A combined evaporating and distillatory apparatus was exhibited by F. A. Wolff and Sons, of Vienna, connected with a copper boiler of about 33 gallons capacity, fixed in a cast iron casing which could be moved from place to place; the boiler was capable of being used also to drive a half-horse power engine. A model of of an apparatus was exhibited by J. Schmidinger, a pharmacist, of Liesing, near Vienna, designed to economize fuel, in which one source of heat could be regulated so as to suffice for one or more operations as required. There were also several kinds of apparatus for the manufacture and manipulation of aerated drinks. One very showy soda-water apparatus, shown by S. Baumann, was nickel-plated; another, which was enamelled in the interior, so as to prevent contact between the water and any metal, and provided with a refrigerating jacket enabling the water to be drawn off at a low temperature, was exhibited by T. Keil, of Halle. There were also specimens of machines for preparing the compressed medicines which are acquiring a certain amount of popularity, exhibited by E. M. Reiniger, of Erlangen, and F. A. Reichardt and Co., of New York.

Group IV.—*Utensils and Appliances that are Necessary or Useful in carrying on the Business of a Pharmacy.*

Exhibits from Austro-Hungary, 35; Germany, 4; England, 1; Denmark, 1: total 41.

Jurors: Messrs. Boettger (Bunzlau), Heindl (Ottakring), Linde (Melk), Madsen (Copenhagen), Pserhofer (Vienna), and Sinnimberghi (Rome).

This very inclusive group, though relatively not of very great importance from a scientific point of view, was certainly not the least interesting to many of the visitors, since here were to be found all the little knick-knacks which, trifling as they may be, assist the pharmacist in maintaining that superior neatness and finish which should be characteristic of all the work he turns out. Paper and paper bags of all kinds and sizes, plain and ornamental labels, envelopes and printed forms, earthenware pots of various patterns for ointments and other preparations, turned wooden boxes and the stamped tin boxes which are so freely and conveniently used on the Continent for small quantities of plaster were among the articles exhibited. There were also some very useful looking enamelled evaporating dishes and other utensils from the manufactory of A. Prickryl, Austerlitz. Corks were extremely well illustrated by C. Rahmer, of Breslau, and R. Pecher, of Vienna, the latter of whom provided the additional attraction of a very graphic representation of the stripping of a cork tree. Mention must be made here too of the very ingenious "Spahnpfropfen," or "shaving stoppers," patented by F. and K. A. Koeller, of Neulengbach. Each of these stoppers is made of a long shaving of soft wood, about ¾ of an inch wide, rolled up into a coil of a diameter to suit the size required and thrust into a tinned capsule open at one end. Although the coil is tightly rolled there is considerable elasticity in the wood, so that the stopper when driven into the neck of a bottle closes it as effectually as a good cork, whilst the cleanliness of such a plug and its non-liability to decay seem to give it a great advantage over inferior corks at least. These stoppers are said to be coming into considerable use for mineral waters. In this group, too, there were some very creditable displays of glass apparatus, bottles, etc., from the Austrian Glass Manufacturing Company's works in Aussig and C. Stoelzle's works in Lower Austria and Bohemia. There were also a few exhibits of balances suitable for pharmacies, that of J. Florenz, of Vienna, appearing to be especially good.

GROUP V.—*Drugs, Chemical Products, Pharmaceutical Preparations and Wares intended for Use in Medicine.*

This group, which was by far the largest and most important in the exhibition, including 172 exhibits from eighteen different countries, was conveniently divided into five sections, a separate jury being appointed for each section.

Section A.—Chemical Products.

Exhibits from Austro-Hungary, 8; Germany, 3; total 11.

Jurors: Messrs. Ludwig (Vienna) and Reichardt (Jena).

Among so large a number of exhibits of a diverse character it would be obviously presumptuous to claim absolute pre-eminence for any, but it may be fairly said that in this section there were two cases,—those of E. Merck, of Darmstadt, and Schimmel and Co., of Leipzig,—which contained specimens that were not surpassed in value and beauty by any in the exhibition. At the same time it was perhaps in this section that the limited internationality of the exhibition became most evident, the names of the majority of the most eminent manufacturers of pharmaceutical chemicals being conspicuous by their absence. Some analogous exhibits of chemical products, however, were included in cases that were placed in other sections, notably one from J. Schorm, of Vienna, and Gehe and Co., of Dresden. The case of E. Merck was crowded with specimens,—several of them of considerable intrinsic value,—not only of the alkaloids and other definite chemical compounds which have received official recognition in the pharmacopœias, but also of almost all that have in recent years been the subject of therapeutic experiment, and it served admirably as an exponent of what has been done by chemists in recent years towards the isolation in a definite form of the active principles of crude vegetable drugs. Among the better known alkaloids shown may be mentioned very fine crystals of morphia and strychnia. The atropine was claimed to be perfectly pure and free from the so-called "light atropine," or daturine, which occurs together with it in the belladonna plant, and, according to Ladenburg, is identical with hyoscyamine. A perfectly white "neutral" sulphate of atropine was shown, as well as the salicylate in crystals. Then there were the hydrobromate and hydriodate of hyoscine, the second alkaloid discovered by Ladenburg in *Hyoscyamus niger*, and said to approach atropine in its action; also homatropine, the synthetically prepared alkaloid and its hydrobromate, still said to present advantages in cases where dilation of the pupil for a short time is desired. There were also caffeine and a definite hydrobromate, as well as caffeine compounds bearing the designations "natrio-benzoicum," "natrio-cinnamylicum," and "natrio-salicylicum," which represented the soluble compounds of that alkaloid recently introduced by Tanret. Pure codeine was accompanied by the phosphate, which has the advantage of being soluble in water to the extent of 1 in 4. It would, however, extend beyond proper limits simply to catalogue here all the specimens exhibited in this case, though it is very difficult to make a selection; it must suffice, therefore, to mention some of the rarer or more recently introduced compounds. Of alkaloids there were aspidospermine and its citrate, from quebracho bark; the febrifuge ditaine, from the bark of *Alstonia Scholaris*; duboisine, prepared from *Duboisia Myoporoides*, said to be still in demand, notwithstanding that Ladenburg has alleged it to be identical with hyoscyamine; gelseminine sulphate and hydrochlorate, from the root of *Gelsemium sempervirens*; hydrastine, from *Hydrastis Canadensis*, used in typhus fever; pelletierine hydrochlorate, sulphate, and tannate, from the root bark of *Punica Granatum*, said to be an efficacious remedy for tapeworm, the tannate being most used; physostigmine, from the Calabar bean, and some of its salts, of which the crystalline salicylate is said to be the most stable and has been included in the new German Pharmacopœia; and sparteine, from *Sarothamnus Scoparius*, which, like the accompanying acid principle, "scoparin," is said to have a diuretic action. Amongst acids, glucosides and neutral principles there were cathartic acid, the active constituent of senna leaves, administered in doses of 0·4 gram to adults and 0·2 to children; "cannabinum tannicum," the new narcotic from Indian hemp; cantharidin, which is to some extent replacing the use of the flies; colocynthidin, a purgative glucoside from the colocynth; convallamarin and convalarin, the former now coming into use as a substitute for digitalis; cotoin and paracotoin, the latter especially said to have a specific action against diarrhœa; cyclamin, from *Cyclamen europæum*, resembling saponin in its action; kosin, the crystalline active principle of kousso flowers; scillipicrin, a diuretic compound from *Scilla maritima*; and podophyllotoxin, which according to Podwyssotzky (*Pharm. Journ.*, [3], xii., 1011) is a compound of picropodophyllin, the active purgative principle of the podophyllum root, with picropophyllic acid, by which it is rendered soluble and assimilable in the stomach. There was also a specimen of white "eucalyptol puriss.," prepared specially for use in medicine by purifying the commercial eucalyptol; it was described as of sp. gr. 0·918 at 15° C. and boiling between 170° and 173° C.

The individual compounds shown in the case of Schimmel and Co. were not nearly so numerous, but the interesting character and rarity of some of them and the volume and beauty of the specimens constituted the whole a most remarkable collection. The specialty of this firm is the manufacture of essential oils and essences for use in perfumery, and in the case some fine samples of essential oils were shown. But what attracted most notice were the solid crystalline principles derived from such oils that were exhibited. For instance, there were anisic acid, in beautiful small crystals, from oil of anise; salicylic acid from oil of gaultheria; cuminic acid from oil of cumin; cinnamic acid from oil of cassia; a splendid crystallization of apiol from oil of parsley; allantcamphor, elecampane camphor or helenin (alantic anhydride) from the essential oil of *Inula Helenium*; matico camphor; white scales of bergamoptene, the stearoptene of oil of bergamot; magnificent crystals of menthol, some approaching 2 inches long, from Mitcham oil of peppermint; and an extremely fine specimen of thymol crystals. But quite as interesting, if not more so, was a dish full of small crystalline needles of heliotropin, the odorous principle of the heliotrope, not prepared, however, from the flowers, but produced synthetically as a derivative from piperine. Another synthetically prepared compound shown was coumarin, the odorous principle of Tonka bean, which was probably obtained by one of the processes referred to on another page. Besides its use in perfumery this compound appears to be in some request for masking the odour of iodoform. In another bottle was about 50 grams of essential oil of iris, a yellowish mass of the consistence of butter, solid at ordinary temperatures and melting at about 40° C. This specimen was said to represent one thousand times its weight of the crude material.

Another class of chemical manufactures, the tar products, was illustrated by the exhibit of J. Ruetgers. Here were to be seen benzol in crystals; toluol and xylol as colourless liquids; naphtaline; chinoline and its hydrochlorate, salicylate, tartrate, and sulphate, the last two as white apparently amorphous powders; pyridine, the probable nucleus of many, if not all, alkaloids, and which, with its homologues, is alleged to possess powerful insecticidal properties; a compound of pyridine and zinc chloride, in white silky flakes, used as a disinfecting material; and carbolic acid in various grades of purity. According to a return made by this firm, and published in the catalogue, its production of pyridine and chinoline amounts to from thirty to forty thousand kilograms yearly. Still another class was represented by the Soap-boiling Works Company of Vienna and F. A. Sarg and Son. Both of these firms exhibited some very fine specimens of glycerine, and displayed considerable ingenuity in showing their chemically pure samples in clear glass vessels that appeared to be quite empty, so free from colour was the glycerine contained in them. According to a statement made on behalf of F. A. Sarg and Son, who carry on a stearin candle-making business founded in Vienna by De Milly, the price obtained for the first glycerine sold from the manufactory was 100 florins per Vienna centner (about 100 lbs. av.), and the amount produced at first was 50 centners per year, rising slowly to 100 centners, until the introduction of glycerine soap and glycerine toilet articles created an increased demand. As the production of glycerine, however, increased the price fell as low as 24 florins the centner, when the introduction of the use of nitroglycerine enormously increased the consumption and the price too.

Other exhibitors in this group were Wagenmann, Seybel and Co., of Liesing, near Vienna, who made a fine display of general chemicals, as did also J. Wurth and Co. and W. Neuber of Vienna. Hartmann and Hauers exhibited "kreosotum verum faginum," as well as a disinfecting compound of creasote and lime. In this case also was to be seen a preparation which, under the name "Essig-Essenz" (vinegar essence), appears to be in use in Austria. It consists of a strong solution of pure acetic acid, which, when further diluted, yields a very palatable table "vinegar." Lastly, milk sugar from the Austrian Tyrol was exhibited by J. Traunsteiner, of Niederdorf, in mass, in rods and as a powder.

(*To be continued.*)

SOPHISTICATED OIL OF CLOVES.

BY G. SPENCER.

Some time since, having begun a series of experiments upon essential oils with ferric chloride, I was struck with the green coloration produced with a few samples of oil of cloves that came under my notice. At that time I did not further trouble, but mention having been made of the same thing by Herr Beckurts in the *Pharm. Centralh.*, xxiv., 377, a *résumé* of which appears in "The Month," I determined to repeat his experiments on a sample obtained for retail purposes a short time ago, with exactly the same results, viz., "yellowish in colour, very weak aromatic taste,"—so weak, indeed, that shaking the bottle and placing the stopper on the tongue did not seem one half so pungent as biting an ordinary clove, —"with odour exactly that of true oil of cloves." I found the sp. gr. to be only 1·02 instead of 1·03 or as it should be, according to the German Pharmacopœia 1·041 to 1·061.

When exposed to bromine vapour a deep black was produced, but no blue nor violet. With ferric chloride a green coloration took place with perhaps a trace of blue at the line of juncture produced by carefully pouring the "oil of cloves" into a solution of ferric chloride in alcohol, but which entirely disappeared on shaking. By distilling a portion and carefully treating the distillate with KHO, and afterwards with argentic nitrate, the latter was reduced and a resplendent mirror formed, proving the presence of a formate. That left in the retort was of a dark brown colour, treacly appearance, and a peculiar faint unpleasant odour. This treated with Fe_2Cl_6 gave a much deeper green than the "oil of cloves." Treated with KHO it was only partially saponifiable, leaving a pinkish-buff deposit, but the odour of cloves to a large extent was restored.

It seems to be a mixture of genuine oil of cloves, with a compound belonging to the creasol class, as the latter gives the same coloration with Fe_2Cl_6. All pharmacists should examine what they now have and receive with caution any new samples into stock, as the kind above referred to came from a first-class London house, and in all probability has been in the market over six months, it being about that time since I first noticed the green coloration with ferric chloride.

ARTIFICIAL COUMARIN.*

Coumarin is found in nature in several plants, as is well known, and especially to a great extent in the well-known fruit of the *Dipterix odorata*, the Tonka bean; further, in the leaves of the *Liatris odoratissima*, growing

* From *New Remedies*, August.

in Virginia, Carolina, and Florida, called "deer tongue" in the American trade. Small portions are also found in the much-liked woodruff (*Asperula odorata*), the melilot trifoil (*Trifolium melilotus*), the sweet smelling grass (*Anthoxanthum odoratum*, and in the leaves of *Angræcum fragrans*, or Faham leaves. All these drugs owe their aroma, and consequently their value, exclusively to the quantity of coumarin they contain, and all the other parts they consist of are not only totally valueless, but in being worked they are as disadvantageous and cumbersome as the well-known extract matter and soft resin of vanilla. These drawbacks having been duly recognized, repeated attempts have been made to produce coumarin from the Tonka bean; this process, however, is not only troublesome, but leads also to losses which make coumarin enormously dear.

Through the production of coumarin by means of synthesis, a real want has therefore been supplied in several respects, and to all those branches of industry which hitherto used it in the shape of the Tonka bean, or in one of the said parts of plants, the opportunity is now presented materially to improve their manufactured articles, to impart to them always exactly the same amount of coumarin, and also—as will be shown—to economize considerably.*

Artificial coumarin was produced, years ago, synthetically; but it has been reserved to our most recent times to perfect the production to such a degree that nature—as in the case of vanillin—has been perfectly attained. The coumarin which is now an article of trade is a production that will convince any one who tests it without bias and prejudice that the Tonka bean has become superfluous, and that its days as an article of commerce are numbered. The perfect chemical equality of the natural and artificial coumarin precludes, in the first instance, any idea of putting the latter in the background. It has neither a weaker aroma than the natnral coumarin, nor is it more volatile, nor less durable, for its melting-point is precisely the same. It is no substitute for the Tonka bean, but for the body which yields the aroma. It possesses the same qualities, and cannot be distinguished from the coumarin extracted from the Tonka bean, either by the senses or by the means employed by the chemist.

The artificial coumarin possesses the important quality of dissolving easily in almost all the fluids employed. It dissolves in water, spirit, ether, glycerin, vaseline, fat oil, and animal fat, in almost any proportion; and there is probably hardly any substance that is practically used in the various industrial branches concerned in which it is not soluble. As soon as the most important point, the production of a perfectly faultless coumarin of chemical purity, had been attained, the next point was to extend its manufacture to a sufficient extent, in order to be able to compete with the Tonka bean, which is being used in larger quantities than is supposed. Only that factory is able to compete which can supply, in case of need, the equivalent of a whole year's return of Tonka beans within the period of a year; for what manufacturer of tobacco, extracts, or perfumery will change his recipe for coumarin without having absolute security for it? This security exists now, and is guaranteed in a manner the Tonka bean market has never presented.

It suffices to cast only a look on the fluctuations in the price of this drug in order to perceive the embarrassment a total failure of the crop would cause to the consuming branches of industry, small deficiencies of the crop having been sufficient to raise prices by 50 and even 100 per cent.! The artificial coumarin presents, consequently, besides the other advantages already enumerated, a complete independence respecting the Tonka bean, and therefore a safe calculation with reference to the articles for which it is employed. It can be preserved in a cool, dark place for any length of time.

The proportion of coumarin with regard to the Tonka bean has been fixed by exact investigations. The average amount of coumarin in superior beans can be estimated at the most at one and one-half per cent., so that consequently those who have used it hitherto would have to employ the following proportions:—One ounce of coumarin for four pounds of the best Tonka beans. The price of coumarin is such that, even if the lowest value of Tonka beans is taken as a basis, the employment of the former is advantageous under all circumstances. Thus, for instance, one ounce of coumarin costs nowadays 3·50 dollars, whilst four pounds of good Tonka beans cannot be procured under 6 dollars, notwithstanding that the crop of this year has yielded the extraordinarily large quantity of about 220,000 pounds. By far the largest portion of the Tonka beans produced is consumed in the United States. New York and Boston alone imported in 1876 about 200,000 pounds. From the above-stated figures it is sufficiently clear that the price of Tonka beans must still drop considerably before the pecuniary advantage which coumarin offers can be balanced. It may be expected that with a larger sale of the latter the cost of production may still be materially reduced, and that the competition of the Tonka bean with coumarin will soon be a thing of the past.

In the manufacture of confectionery and perfumery, coumarin is now extensively used, and its successful introduction and adoption by those who have tried it, has created a large demand; to fill which, some competitors have not scrupled to partially remove the crystals from Tonka beans, and sell these crystals as pure coumarin. To such an extent has this practice been indulged in that it is now almost a rarity to procure fully crystallized Tonka beans, and consumers who pay for prime beans, and are entitled to full value, should protest against a usage so detrimental to them.

Coumarin is one of the most effective agents to cover the odour of iodoform. About 1 or 2 grains to the drachm will generally be found sufficient.

* The artificial production of coumarin may be accomplished in several ways. For instance, by warming sodium salicylaldehyde ($NaC_7H_5O_2$) with anhydrous acetic acid, or by boiling salicylaldehyde with sodium acetate and anhydrous acetic acid. Recent improvements in the process have greatly shortened the time and expense of preparation.

TINCTURA FERRI CHLORIDI.*

BY MIMMS WILLIAM COLEMAN, PH.G.

As much discrepancy of opinion exists regarding the desirability of retaining the alcohol in the preparation of tinct. ferri chloridi, it has seemed of interest to institute a series of experiments bearing upon this point, and also to extend the investigation to the determination of the result of other influences upon the preparation.

In preparing the liquor ferri chloridi, according to the formula of the U.S. Pharmacopœia of 1880, the mixture of iron, acid and water is to be raised to the boiling point after the cold mixture has ceased to effervesce. If the mixture be boiled at this point, a large quantity of the acid will be driven off and thus lost; and if the solution be filtered at the time directed, only about one-third of the acid will be neutralized. Much better results are obtained by a gentle heat applied for several hours, until effervescence again ceases, when the solution should be raised to the boiling point and filtered. After careful manipulation, using pure acids of the proper strength, the solution was found to have the specific gravity 1·390, and this was the highest that could be obtained by following the directions of the Pharmacopœia, which requires a density of 1·405.

On investigating the cause of this, it was observed that the admixture with nitric acid was to be performed in a capacious porcelain vessel. If so mixed, a considerable quantity is lost by the energy of the reaction, and the loss materially reduces the specific gravity of the resulting solution. It is probable that the experiments incident to the construction of this formula were made in a flask,

* From the *American Journal of Pharmacy*, August, 1883.

which would prevent the loss of any portion of the liquid.

If this conclusion be correct, the specific gravity of the officinal solution is certainly wrong. On inquiring among pharmacists, it was found that the same trouble had been experienced by others.

The Pharmacopœia states that 10 grams of the solution, when completely precipitated by ammonia (NH_4OH), yields a precipitate which, when washed, dried, and ignited, should weigh 1·86 gram. These directions having been followed precisely, with a solution of less specific gravity (1·390) than the officinal, the residue weighed 1·882 gram. With the solution specific gravity 1·390, the tincture was then made according to the officinal formula. The specific gravity was ·965, while the officinal is stated to be about ·980.

Ten specimens of tinct. ferri chloridi, U.S.P., 1880, were obtained from leading pharmacists of Philadelphia. These answered to the tests for purity, but the specific gravities of all were found to vary between ·950 and ·970, except one, which was 1·005, and which proved to have been made with diluted alcohol instead of alcohol specific gravity ·820.

To ascertain the amount of iron present in each, a solution of potassium permanganate was made, 3·14 gm. $K_2Mn_2O_8$, being dissolved in 1000 c.c. distilled water. Theoretically, 1 c.c. of this solution should be equivalent to 0·0056 gm. pure iron; but from a number of determinations made with pure iron wire, it was ascertained to be equal to 0·00537 gm. iron, and this number was employed as the "factor of correction."

To 5 gm. of the tincture, weighed accurately, 3 gm. of metallic zinc, with dilute H_2SO_4 was added, and the mixture, heated, excluded from air until effervescence ceased. It was then cooled and quickly titrated with potassic permanganate solution, until a pink coloration of the liquid occurred. The number of c.c. used was 52·1; multiplied with 0·00537, it indicated 0·279777 gm. iron; but from this number was subtracted 0·023896, the known amount of iron contained in the zinc as impurity, which gives 0·25588 gm. in 5 grams, or 5·1176 per cent. of iron present in the tincture; this is equal to 14·8357 per cent. of Fe_2Cl_6, and to 24·6395 per cent. of $Fe_2Cl_6.12H_2O$.

The following tables will show quite a variation in the amount of iron, etc., present, even when the specific gravities are the same. This can be easily explained by the variations in the specific gravities of the liq. ferri chloridi and alcohol used:—

Spec. grav.	Use 5 gm. of tincture.				Percentage in tincture of		
	$K_2Mn_2O_8$.	Total iron.	Iron in zinc.	Iron in tincture.	Iron.	Fe_2Cl_6.	$Fe_2Cl_6.12H_2O$.
	c.c.						
·965	52·1	·279777	·023896	.25588	5·1176	14·8357	24·6395
·970	52·1	·279777	·023896	·25588	5·1176	14·8357	24·6395
·965	39·5	·212115	·023896	·188219	3·7642	10·9124	18·1137
·970	51·5	·276555	·023896	·252659	5·0532	14·6435	23·8367
·965	50·1	·269037	·023896	·245141	4·9028	14·213	23·6562
1·005	57·4	·308234	·040828	·25741	5·1482	14·9241	24·6405
·967	52·0	·279240	·023896	·25534	5·1068	14·8047	24·6405
·958	48·1	·268297	·023896	·2444	4·888	14·1704	23·5848
·960	48·6	·262982	·023896	·239086	4·7817	13·8062	23·0714
·960	53·3	·286221	·023896	·262325	5·2465	15·0936	25·3189

Attention was now directed to the action of sunlight on the tincture and aqueous solution of iron; for the latter, liquor ferri chloridi, 35 parts, was mixed with distilled water, 65 parts. The specific gravity of this solution was 1·100; it was of a yellowish-brown colour, slightly lighter than the tincture. On analysis with potassic permanganate solution, the amount of iron, etc., present was found to be as follows:—

	$K_2Mn_2O_8$.	Iron, total.	Iron in zinc.	Iron in liquid.	Percentage of		
					Iron.	Fe_2Cl_6.	$Fe_2Cl_6+12H_2O$.
	cc.						
Tincture, 5 gram . .	55·8	·299546	·023896	·27565	5·513	15·9807	26·6004
Aqueous solution, 5 gram . .	47·7	·256049	·023896	·232153	4·64402	13·4639	21·4438
Liq. ferri chlo. (U.S.P.), 1·390, 2 gram . .	53·8	·28929	·023896	·265394	13·2627	38·0511	63·334

Three specimens each of the alcoholic tinctures and solutions were then exposed to the action of the sun's rays for various lengths of time. The alcoholic tinctures were found to change to a greenish-brown or blackish-green colour, according to the duration of exposure, from partial reduction to ferrous chloride, while in both colour and composition the aqueous tincture remained unchanged. The appended table shows the amounts of ferrous salt reduced by the action of sunlight from the ferric state:—

Exposure.	$K_2Mn_2O_8$.	Iron in ferrous state	Iron in ferric state.	P. c. of ferrous iron.
Tincture, 2 weeks.	23·5	·126195	·149455	45·79
Tincture, 4 weeks.	31·4	·168618	·107032	60·909
Tincture, 6 weeks.	48·3	·259371	·016279	94·054
Aqueous solution, 2, 4 and 6 weeks.	None.	None.	..	..

A specimen each of the alcoholic and aqueous solutions was exposed to the action of sunlight and air. On examination it was seen that the reducing action of the alcohol overcame, to a considerable extent, the oxidizing action of the air, as will be seen by the following table:—

	No. c.c. $K_2Mn_2O_8$ used.	Amount of ferrous iron present.	Amount of ferric iron present.	Per cent. of ferrous iron.
Alcoholic tincture exposed to sun and air eight weeks .	32·5	·174528	·099370	63·5154

The aqueous solution was not affected in the least.

The theoretical amount and percentage of iron, etc., of the officinal solution and tincture is shown in the appended table:—

	Amount of iron.	Per cent. of iron.	Per cent. of Fe_2Cl_6.	Per cent. of $Fe_2Cl_6.12K_2O$.
Liq. ferri chloridi in 2 gm. .	·2604	13·02	37·6878	68·8211
Tinct. ferri chloridi in 5 gm. .	·22820	4·564	13·2308	22·015

The estimations of the percentage strength of the officinal preparations were made from the gravimetric test of the Pharmacopœia, the accuracy of which has been shown to be doubtful. The percentage of anhydrous ferric chloride stated in the Pharmacopœia description of liq. ferri chloridi is 37·8. As seen by the foregoing tables, the pharmacopœial solution and tincture contain less iron and iron salts than the commercial preparations, and also the preparations made for these experiments, although the pharmacopœial preparations are said to be of higher specific gravities.

Professor Attfield strongly advocates the discarding of the alcohol in the tincture. He holds that it is unnecessary, expensive, and positively injurious. The only advantage claimed for its use is that it reacts with free acid to form chloric ether, which is believed, by some practitioners, to be of medicinal advantage. If chloric ether is desired, why not dissolve a specified amount in alcohol and, when so desired, add it to the aqueous tincture, which is not altered by light and air? In this way an expensive ingredient would be dispensed with and a known amount of ether obtained.

STUDIES IN THE CHEMISTRY OF TARTARIC ACID.*

BY THE LATE B. J. GROSJEAN.†

1. Action of Solutions of Potassium and Sodium Sulphate on Calcium Tartrate.

The observations recorded in this section were commenced in 1876, and continued at intervals in the two following years.

Although a solution of calcium sulphate produces no precipitate in solutions of neutral tartrates, yet an excess of moist gypsum will, as is well known, precipitate almost the whole of the tartaric acid from neutral solutions of potassium tartrate. This reaction is, in fact, regularly employed in the manufacture of tartaric acid. The crude tartar in the factory is first boiled with water and neutralized with chalk (whiting). Half the tartaric acid is thus precipitated as calcium tartrate, while the other half remains in solution as neutral tartrate of potassium. The addition of an excess of moist gypsum decomposes this potassium tartrate, sulphate of potassium and calcium tartrate being produced. Mr. Grosjean has found that under certain conditions the reaction last mentioned may be entirely reversed, and that by attacking calcium tartrate with a hot and sufficiently strong solution of potassium or sodium sulphate, practically the whole of the tartaric acid may be brought into solution as tartrate of potassium or sodium. The results obtained with solution or potassium sulphate shall be first mentioned.

1. Four grams of calcium tartrate were heated with 30 c.c. of water, 10 grams of potassium sulphate next added, and the whole heated in a water-bath for half an hour. The contents of the beaker were then placed on a vacuum filter, and the residue quickly washed with water. The small quantity of lime in the filtrate and washings was removed with a little potassium oxalate, the liquid concentrated to 60 c.c., and the tartaric acid present precipitated as acid potassium tartrate by the addition of 2 grams of citric acid and 3 grams of potassium chloride. The tartaric acid obtained amounted to 2·1931 grams. The calcium tartrate taken (analysed by digestion with potassium oxalate and precipitation with citric acid) had contained 2·2033 grams of tartaric acid. The action of the potassium sulphate was thus very complete, 99·5 per cent. of the tartaric acid taken being obtained as potassium tartrate.

2. A duplicate experiment was made, the only alteration being that after heating the whole was allowed to stand an hour and become cold before filtering commenced. This alteration did not distinctly affect the result, the tartaric acid found in solution being 2·1627 grams, or 98·2 per cent. of that taken as calcium tartrate.

Two series of experiments were next made to ascertain the effect of varying proportions of potassium sulphate, and also the influence of varying degrees of dilution. The mode of conducting the experiments was in general that above described. The calcium tartrate employed was not quite pure; the tartaric acid it contained was determined by the neutralizing power of its ash. The amount of water present during each digestion was also somewhat roughly ascertained. The results of the experiments nevertheless plainly indicate the general influence which different proportions of potassium sulphate and of water exert in this reaction. The results will be found in Table I.

Table I.—Tartaric Acid obtained as Potassium Tartrate by the Action of Potassium Sulphate on Calcium Tartrate.

No.	Materials taken—grams.			Tartaric acid obtained as potassium tartrate.		
	Tartaric acid as calcium tartrate.	Potassium sulphate.	Water.	In grams	For 100 taken.	For 100 of potassium sulphate.
1.	2·2033	10	30	2·1931	99·5	21·9
2.	—	—	—	2·1627	98·2	21·6
a	1·1270	5	15	1·0690	94·9	21·4
b	—	—	25	1·0035	89·0	20·1
c	—	—	50	0·9478	84·1	19·0
d	—	—	100	0·7332	65·1	14·7
e	0·5635	2·5	15	0·4650	83·4	18·6
f	—	2·0	—	0·3557	63·1	17·8
g	—	1·0	—	0·0060	1·1	0·6

In experiments *a—d* the quantities of calcium tartrate (2 grams) and of potassium sulphate (5 grams) remain constant, while the quantity of water is varied. The results plainly show that as the proportion of water increases, the decomposing effect of the potassium sulphate diminishes.

In experiments *e—g* the proportion of potassium sulphate is varied, the other bodies remaining constant. We here see the prejudicial influence of dilution intensified by a gradual reduction in the proportion of the potassium sulphate. According to the last experiment, 1 gram of potassium sulphate with 15 c.c. of water has scarcely any decomposing effect when heated with 1 gram of calcium tartrate.

Mr. Grosjean soon ascertained that the product of the action of potassium sulphate on calcium tartrate was not calcium sulphate, but the double sulphate of calcium and potassium. He found also that the latter salt was readily decomposed by water. Ditte (*Compt. Rend.*, 79, 1254; *Journ. Chem. Soc.*, 1875, 332) has shown that the double sulphate can exist in contact with water only when a certain excess of potassium sulphate is present in solution. At 15° the solution must contain at least 2·5 per cent. of potassium sulphate for the double salt to remain permanent; if less is present, the double salt is decomposed by the water till sufficient potassium sulphate is brought into solution to produce the condition of equilibrium mentioned. The higher the temperature the greater will be the excess of potassium sulphate required to produce equilibrium. Mr. Grosjean studied the action of water on the double sulphate of calcium and potassium at a temperature of about 20°. Three successive treatments with water gave solutions containing respectively 2·96, 2·86, 2·81 per cent. of potassium sulphate. These results agree with the earlier ones of Ditte, with which Mr. Grosjean was, I believe, at this time unacquainted. The same three solutions contained respectively 0·19, 0·17, 0·17 per cent. of calcium sulphate.

The facts just mentioned seem to throw some light on the results of the previous experiments. If we look at the reaction between potassium sulphate and calcium tartrate in its simplest aspect, and shut out from view any mere influence of mass, we shall probably conclude that calcium tartrate containing 1 gram of tartaric acid would require for its decomposition the amount of potassium sulphate (2·323 grams) necessary to produce sulphate of calcium and potassium, with, in addition, an excess of potassium sulphate amounting to 2·5 per cent. of the solution at 15°, and increasing with a rise in the temperature

* From the *Journal of the Society of Chemical Industry*, Aug. 29, 1883.

† Mr. B. J. Grosjean was for many years the chemist at Sir J. B. Lawes's Tartaric and Citric Acid Factory, Millwall. The following abstract of some of his unpublished investigations has been compiled by Mr. R. Warington from reports made by Mr. Grosjean, and from his Laboratory Note-books. The results are made public by Sir J. B. Lawes's permission. Further investigations by Mr. Grosjean will be found in the *Journ. of the Chem. Soc.* for July last. See also *Pharm. Journ.* [3], xiii., 435.

employed. With each increase in the dilution there would clearly be an increase in the quantity of potassium sulphate required to produce the excess demanded. Mr. Grosjean does not appear to have made any trials as to the possibility of the reaction taking place at a low temperature. All his experiments were conducted near a boiling heat.

The reaction with sodium sulphate differs in several respects from that with potassium sulphate. The precipitate produced by the action on the calcium tartrate is not nearly so bulky. To what extent it consists of a double sulphate of calcium and sodium was not determined. At a temperature near boiling, and with a favourable proportion of water, a considerably smaller quantity of sodium sulphate than of potassium sulphate is required to decompose a unit of calcium tartrate. On cooling, however, a reverse action sets in, and a considerable part of the tartaric acid again becomes tartrate of calcium. In the case of potassium sulphate we have already seen that the action is not reversed on cooling.

The experiments quoted in the following table are best comparable with those numbered *a—g* in the trials with potassium sulphate. The reaction was in all cases conducted on a water-bath, and the contents of the beaker transferred while hot to a vacuum filter. The tartaric acid dissolved was determined by the ignition method.

Table II.—Tartaric Acid obtained as Sodium Tartrate by the Action of Sodium Sulphate on Calcium Tartrate.

No	Materials taken—Grams.			Tartaric acid obtained as sodium tartrate.		
	Tartaric acid as calcium tartrate.	Sodium sulphate.	Water.	Grams.	For 100 taken.	For 100 of sodium sulphate.
1	2·2212	6·00	15	1·0830	48·7	18·1
2	1·6629	6 00	30	1·6425	98·8	27·4
3	1·1106	3·00	—	0·9214	83·0	30·7
4	—	1·50	—	0·4551	41·0	30·3
5	—	0·75	—	0·2168	19·5	28 9

It appears from these experiments that sodium sulphate may be used economically as a 10 per cent. solution. At this strength 3 grams of sodium sulphate are almost as efficient as 5 grams of potassium sulphate, as may be seen by comparing experiments *c* in Table I. with experiment three in Table II. In experiment one the inferior result per unit of sodium sulphate seems due to the employment of too small a proportion of water. When the sodium sulphate does not exceed 10 per cent. of the solution, very considerable variations, both in the degree of dilution, and the proportion of calcium tartrate present, may apparently occur without producing any large alteration in the decomposing efficiency of the unit of sodium sulphate: a result certainly different from that observed in the experiments with potassium sulphate.

It is clear that further experiments are required to elucidate the subject.* If, however, we may assume that a double sulphate of sodium and calcium was not formed in experiments two to five, many of the differences from the results obtained with potassium sulphate admit of at least a partial explanation. On this hypothesis the sodium sulphate would not be partially precipitated with the calcium sulphate, and a much smaller proportion of sodium sulphate than of potassium sulphate would therefore be required to decompose a unit of calcium tartrate. Dilution would also have a far less injurious effect on the sodium reaction, for here it is not necessary, as in the potassium reaction, to maintain a certain percentage of alkali sulphate in the solution in order to determine the reaction with the calcium tartrate. But this advantage on the side of the sodium sulphate is confined to a high temperature, for, on cooling, the calcium sulphate again combines with the tartaric acid. Not so in the potassium reaction. Here there is no calcium sulphate, and the double sulphate of calcium and potassium that is present becomes, as we have seen, more stable as the solution cools.

If any of the solutions of potassium or sodium tartrate obtained in the above experiments are considerably diluted, and an excess of solid sulphate of calcium added, nearly the whole of the tartaric acid will be precipitated as calcium tartrate.

(*To be continued.*)

* Fritzsche (*J. Pr. Chem.*, 72, 294) obtained the double sulphate of sodium and calcium only in very strong solutions.

MANUFACTURE OF CAMPHOR IN JAPAN.*

The manufacture of camphor is an important industry on the island of Kiu Shiu (Kew Shew).

From the port of Nagasaki there were exported in the year 1882, 15,186·18 piculs, valued at 227,792 dollars. A picul is 133⅓ pounds. From other ports of the island not yet open to foreign trade, a large quantity was shipped by native merchants in native vessels to Shanghai in China, and Hong Kong, whence it finds its way to India and England; little or none of it is exported to the United States. The camphor tree grows abundantly all over this portion of Japan. It is found alike on high elevations and in the valleys and lowlands. It is a hardy, vigorous, long-lived tree, and flourishes in all situations.

Many of these trees attain an enormous size. There are a number in the vicinity of Nagasaki which measure ten and twelve feet in diameter. The ancient temple of Osuwa at Nagasaki is situated in a magnificent grove of many hundred grand old camphor trees, which are of great age and size, and are still beautiful and vigorous. I am told that there are trees in other places in Kiu Shiu measuring as much as twenty feet in diameter. The body or trunk of the tree usually runs up twenty and thirty feet without limbs, then branching out in all directions, forming a well proportioned, beautiful tree, evergreen and very ornamental.

The leaf is small, elliptical in shape, slightly serrated, and of a vivid dark-green colour all the year round, except for a week or two in the early spring, when the young leaves are of a delicate tender green. The seed or berry grows in clusters and resembles black currants in size and appearance. The wood is used for many purposes, its fine grain rendering it especially valuable for cabinet work, while it is used also for ship-building. The roots make excellent knees for ships.

I have sent many seeds of the camphor tree to the United States, in the hope of adding to our own arboriculture.

In the manufacture of camphor the tree is necessarily destroyed, but, by a stringent law of the land, another is planted in its stead. The simple method of manufacture employed by the natives is as follows:—

The tree is felled to the earth and cut into small pieces, or, more properly speaking, into chips.

A large metal pot is partially filled with water and placed over a slow fire. A wooden tub is fitted to the top of the pot and the chips of camphor wood are placed in this. The bottom of the tub is perforated, so as to permit the steam to pass up among the chips.

A steam-tight cover is fitted on the tub. From this tub a bamboo pipe leads to another tub, through which the inclosed steam, the generated camphor, and oil flow. This second tub is connected in like manner with a third.

The third tub is divided into two compartments, one above the other, the dividing floor being perforated with small holes, to allow the water and oil to pass to the lower compartment. The upper compartment is supplied with a layer of straw, which catches and holds the camphor in crystal in deposit as it passes to the cooling process. The camphor is then separated from the straw, packed in wooden tubs of 133⅓ pounds each, and is ready for market.

After each boiling the water runs off through a faucet, leaving the oil, which is used by the natives for illuminating and other purposes.

SATURDAY, SEPTEMBER 8, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W.* *Envelopes indorsed "Pharm. Journ."*

THE INFLUENCE OF LEBLANC'S DISCOVERY OF THE PROCESS FOR MAKING ALKALI UPON THE HISTORY OF CHEMICAL MANUFACTURES.

ABOUT ninety years have now elapsed since the outbreak of war consequent upon the French revolution led to the stoppage of the importation into France of barilla from Spain, and caused the National Convention to consult the Academy of Sciences as to the possibility of obtaining a supply of the indispensable alkali from a native source. The chemists of that body were unanimous in pointing to common salt as the most promising and suitable material, and upon their report a prize of twelve thousand francs was offered for the person who should work out the best practicable process for obtaining from it what was required. The offer called forth thirteen competitors, one of whom was NICOLAS LEBLANC, a pharmacien, with his process —essentially the same as practised in the present day—of treating the common salt with sulphuric acid, and converting the sulphate of soda formed into carbonate by calcination with a mixture of coal and chalk. The award was made in favour of LEBLANC; but by that time the Academy had ceased to exist, and the well-earned reward was not forthcoming. Nor was this the last of LEBLANC'S misfortunes; there was an unsuccessful attempt to carry out the manufacture to which the sequel was bankruptcy, followed by a miserable struggle for existence and then—suicide! His lot, like that of many another inventor, was to lack comforts and even food whilst living and after death to be covered with honour, which, it appears, is now to culminate in the erection of a statue by the municipality of Issodoun, the town where he was born. On a recent occasion this project was brought under the notice of the Academy of Sciences, which now represents the body dissolved by the Convention, by its eloquent and gifted Perpetual Secretary, M. DUMAS, who availed himself of the opportunity to deliver a discourse on the "historical *rôle* of the discovery of artificial soda extracted from sea-salt," in which he recounted some facts that are well worth remembering at a time when it seems possible that if LEBLANC'S process be not altogether abandoned, it will not much longer be carried on primarily for the manufacture of carbonate of soda.

Few have been the discoveries that have so largely and beneficially affected the human race as that of utilizing common salt in the production of carbonate of soda, and M. DUMAS does not hesitate to couple the names of LEBLANC and WATT as those of the two men whose inventions have been most prolific of benefits to mankind. Although probably there will be many who—not being Frenchmen—will hardly be prepared to accede to this claim in its entirety, it must be admitted that the consequences of LEBLANC'S discovery have been very important and far reaching. Looking to the production of carbonate of soda alone, as the immediate object of the process, it is estimated that the present annual consumption of it in the two hemispheres reaches seven or eight hundred thousand tons, and M. DUMAS speculates as to whether the amount used, more or less unwittingly, by individuals does not approach or even equal the amount of common salt necessary to supply their wants. As the manufacture of soda by the LEBLANC process spread there was an immense development in the manufacture of sulphuric acid and a proportionately increased demand for sulphur, which eventually pressed the hitherto useless pyrities into useful service. On the other hand there was an enormous quantity of gaseous hydrochloric acid set at liberty by the decomposition of the salt. The primary result, therefore, of the institution of works for the manufacture of soda from sea-salt was not only to place at the disposal of those who carried on the glass, soap, and other industries the supply of alkali of which they were in need, but also to provide in unlimited quantity two powerful acids at fabulously reduced prices. A secondary result was to place at the disposition of the manufacturers of textile fabrics and paper a new product derived from hydrochloric acid, "chloride of lime," which for the rapid bleaching of vegetable tissues has taken the place formerly occupied by the slow action of light and moist air. These four agents, a powerful alkali, two energetic acids, and a bleaching powder that nothing has yet replaced, imparted an immeasurable impetus to the industry of chemical products, whilst the necessity which has existed for avoiding the accumulation of bye-products that would be detrimental to the public health and convenience has been a very fertile source of chemical discovery. For instance, the manufacture of chlorine and chloride of lime used up peroxide of manganese and produced chloride of manganese in large quantities. The peroxide was a natural product, limited in its supply, and an increased demand was followed by an exaltation of the price, whilst the accumulations of chloride sterilized the land and contaminated the watercourses. But chemists set to work and the difficulty was overcome by the discovery of an economical method of regenerating the peroxide. In like manner much ingenuity and skill have been devoted to the recovery of the sulphur from alkali waste.

At the present time the LEBLANC process is under a cloud, and the conditions under which it may be able to survive the rivalry of the more modern ammonia process have been eloquently discussed on a recent occasion by the present President of the Society of Chemical Industry. It may be that it will take a fresh lease of life, and with new objects to be attained may regain in some degree its former importance. But however this may be there is some ground for the congratulations of M. DUMAS that the discovery of the ammonia process did not precede LEBLANC'S invention, instead of following it at an interval of nearly a century. But whether it be true, as he affirms, that if the reverse had been the case the industry of chemical products would be yet unborn, that manufacturers would not now have at their disposal cheap sulphuric and hydrochloric acids and chloride of lime, and that agriculturists would not have learnt the use of acid phosphate of lime, is at least somewhat doubtful. In any case the results of the discovery of NICOLAS LEBLANC have been sufficiently beneficial to the world to justify the tardy honour which is to be offered to his memory in his native city, and that is a fact which can hardly be affected by speculations as to what might have been had he lived a century later.

BRITISH PHARMACEUTICAL CONFERENCE.

WE need hardly remind the majority of our readers that the British Pharmaceutical Conference is this year to hold its Annual Meeting in Southport, under the presidency of Professor ATTFIELD, F.R.S., on Tuesday the 18th and Wednesday the 19th inst. In a recent number (see before, p. 9) we alluded to the general arrangements, and need only repeat that the meeting will take place in the Assembly Rooms of the Prince of Wales Hotel, commencing at half-past ten each day, with an interval in the middle of the day for an opportunity to enjoy the hospitality of the local members at luncheon. We are informed that it is now definitely arranged that an opportunity shall be afforded to members, after the close of the meeting on Wednesday, to inspect the works of the Glaciarium and that a demonstration of GAMGEE'S process of making the ice will on that occasion be made. The Local Committee will also invite members to visit St. Helen's on Thursday. Special saloon carriages for the accommodation of the company will be attached to the train leaving Chapel Street Station at 8.10 a.m., and permission has been obtained for the inspection at St. Helen's of the Union Plate Glass Works, the Copper Smelting Works of Messrs. BIBBY, SONS AND Co., and the Chemical Works of Messrs. KURTZ AND Co. The return journey will be made in time for members to be present at a garden party to be held in the Botanical Gardens, Churchtown. In addition to the attractions of the Gardens and Fernery, a full military band will play a selection of music, a company of CHARLES HALLÉ'S choir will give a series of part-songs, glees and choruses throughout the afternoon, and Mr. LEO GRINDON will exhibit a collection of rare and interesting plants, and deliver a short descriptive lecture upon them. Double tickets of invitation will be issued to members, so that it may be hoped that a large proportion of the company will consist of members of the fair sex, whose presence will doubtless add greatly to the enjoyment of the occasion. It will be seen from the list below that as regards the business portion of the proceedings the papers deal with subjects having great pharmaceutical interest, and as regards the entertainment of visitors it is evident that the Local Committee must have laboured indefatigably to provide such a full and attractive programme as we have sketched out on this and on a previous occasion. We therefore venture to anticipate that the combined prospects of scientific and social intercourse will induce a large number of members to visit Southport, and that the forthcoming meeting will be as numerously attended as any of its predecessors. For the convenience of those who will have to travel from London, it may be again stated that through carriages will be attached to the trains leaving Euston at 7.15 a.m., 11 a.m., 1.30 p.m., 3 p.m., and 4 p.m., on the 17th, 18th, and 19th inst.

We are informed by the General Secretaries that the following papers have already been promised for the meeting:—

1. Second Report on the Differences between the Essential Oils of Cinnamon and Cassia. By A. H. JACKSON, B.Sc.
2. Bitter Principles of Nerium Odorum: Preliminary Report. By H. G. GREENISH, F.I.C.
3. Report upon the Quantitative Separation of Strychnine and Brucine. By WYNDHAM R. DUNSTAN F.C.S., and F. W. SHORT.
4. Report on Tincture of Nux Vomica. By WYNDHAM R. DUNSTAN, F.C.S., and F. W. SHORT.
5. The Preservation of Medicinal Herbs by Ensilage. By Professor QUINLAN, M.D., M.R.I.A.
6. The Pharmaceutical Aspects of the Mullein Plant. By Professor QUINLAN, M.D., M.R.I.A.
7. Aconitine for Internal Exhibition: its Certainty and Safety. By T. B. GROVES, F.C.S.
8. Contribution to the Pharmacy of the Pomegranate. By L. SIEBOLD, F.I.C., F.C.S.
9. Experiments on the Ointment Bases. By W. WILLMOTT.
10. Suggestions for Combinations of Collodion. By J. B. BARNES, F.C.S.
11. Sweet Spirit of Nitre. By A. C. ABRAHAM.
12. Sesame Oil: its Suitability for Pharmaceutical Purposes. By T. MABEN.
13. Sesame Oil: Report on its Suitability for Pharmaceutical Purposes. By M. CONROY, F.C.S.
14. The Composition of Easton's Syrup. By R. H. DAVIES, F.I.C., F.C.S.
15. The Odorous Principles of Henbane. By A. W. GERRARD, F.C.S.
16. Does Cod Liver Oil contain Iodine? By E. C. C. STANFORD, F.C.S.
17. Additional Notes on the Bitter Principle of Hymenodictyon Excelsum. By W. A. H. NAYLOR, F.C.S.
18. On the Trees yielding Benzoin. By E. M. HOLMES, F.L.S.
19. On some Asphalts and Pitches of Commerce. By E. DAVIES, F.I.C., F.C.S.
20. A paper by B. D. DOTT, F.R.S.E.

We are informed by a local correspondent that in the case of accidental poisoning at Partick, to which reference has been made previously, the prosecution of the dispenser has been abandoned. It is understood that it was found that the bottle used in the dispensing while distinctly labelled "Tinct. actææ" contained a mixture of the tinctures of actæa and aconite. Also that a supply of tinct. of actæa had been procured from two wholesale houses, by either of which aconite might have been sent by mistake. In addition the shop had been recently refitted with recess-labelled bottles, and the mistake might have been made in transferring the preparations to the new bottles. There was thus no case against the assistant, and he was discharged by the Crown. There however, remains still a possibility of a civil action against the proprietor.

* * *

In an interesting paper on "Modern Therapeutical Tendencies," contributed to the *British Medical Journal*, Dr. J. H. Bennet refers to the want of pharmaceutical knowledge in the rising generation of medical practitioners. Evidence of this is to be found, he thinks, in the advertising columns of the medical journals. The young doctors of the present day not knowing how to prescribe, the chemists of the present day prove equal to the occasion and provide them with formulæ ready cut and dried, which appear to be rapidly gaining ground. Surely, Dr. Bennet says, a well-informed medical practitioner ought to know how to combine and prescribe medicinal agents better than his chemist. Dr. Bennet adopts somewhat of a monitory tone towards pharmacists on this subject, warning them that the system cuts both ways, since it is antagonistic to their legitimate business, and that while building up the fortunes of a few large advertising houses, they diminish their own profits, notwithstanding that they receive a large commission. We do not think, however, that pharmacists need to be reminded of this fact. It is the first business of the dispesnser to meet the wishes of the prescriber by using, as nearly as possible, the exact articles ordered in a prescription, and as long as prescribers allow themselves to be persuaded into abandoning the Pharmacopœia in favour of the private formulary the dispenser has no option as to following his lead.

* * *

An Act to regulate the practice of pharmacy in the state of Delaware has been passed, which makes it illegal for other than registered persons to "conduct any pharmacy or store vending at retail, dispensing or compounding medicine or poisons within the corporate limits of any town of five hundred inhabitants or over" in that state. The first Board of examiners is to be nominated by the State Medical Association and is to consist of the "most skilled and intelligent pharmacists in the state;" the examiners, however, are not to receive any remuneration, neither is the nature of the examination defined.

* * *

In the opinion of Mr. Morris, the Director of the Government Plantations in Jamaica, who has recently visited British Guiana, the cinchona plant is very unlikely to thrive in either British Honduras or British Guiana, and as he has not much faith in the systematic cultivation of it in its natural home in the South American States, whilst all attempts at its naturalization in the United States have failed, he thinks it very likely that for many years to come Jamaica will remain the site of the only successful cinchona plantations in the New World. In that island plantations are now being laid out by private persons on a large scale, and during the last two years the Government has sold twelve patents, or runs, of high forest land, containing about five thousand acres, under conditions which require that at least one-sixth shall be planted with cinchona at the end of five years.

* * *

Some little excitement has been created among importers of cinchona alkaloids and their salts into the United States by the discovery that when the Act was recently passed repealing the duty on quinine and its salts and cinchonidine, sulphate of cinchonidine—probably through an oversight—was not mentioned. The Act provides that all alkaloids and their salts, by whatever name known, if not specially enumerated as exempt, shall pay a duty of 25 per cent. *ad valorem*. As the enumeration in the free list is limited to "quinia, sulphate of, salts of, and cinchonidia," the collectors at the ports have decided that sulphate of cinchonidine is liable to pay the duty, and notwithstanding an appeal to the authorities they will probably maintain their ground.

* * *

One of the inevitable consequences, however, of maintaining high import duties is shown in the significant statement that in consequence of the rigorous action of the Government in prosecuting opium smugglers on the Pacific coast, the duties on opium collected at San Francisco during the last fiscal year amount to one million dollars in excess of the amount collected from the same source in the previous year.

* * *

According to the *British Medical Journal*, a student in the College of New York has been fatally poisoned by morphia supplied in a capsule in the place of quinine. The proprietor of the drug store from which the capsule was obtained, and the assistant who sold it, have been committed for trial.

* *

It may be useful to some of our readers who use Professor Babington's 'Manual of Botany' to know that the author has prepared two pages of corrections and additions for the eighth edition, copies of which may be obtained gratis from the publisher, Mr. Van Voorst.

* * *

In a communication to the French Academy of Sciences M. Krechel has called attention to an adulteration of milk effected by the addition to it of an aqueous solution of commercial glucose, having the same density.

* * *

An attempt to organize amongst manufacturers and dealers in proprietary articles in the United States, a mutual protection association for the defence of trade marks, which was set on foot about a year ago, appears to have collapsed, only six firms having shown any disposition to join it.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.

Weather Knowledge in 1883.*

BY ROBERT HENRY SCOTT, M.A., F.R.S.,

Secretary to the Meteorological Council.

Rather more than ten years since I had the honour of delivering a Friday evening lecture in this theatre, and my subject on that occasion was somewhat similar to that which I have chosen for this evening. It was then "Recent Progress in Weather Knowledge," and to-night I must endeavour to lay before you the results of ten years' further experience of a work of which the complexity becomes daily more patent.

Dealing first with the forecasting of the character of seasons. In 1873 the theory of a connection between the frequency of sun-spots and the weather had been recently promulgated, and appeared to promise most valuable results. It is universally admitted that the presence of spots on the solar surface indicates increased activity in his gaseous envelope, which ought to and must affect our atmosphere.

A connection between the frequency of sun-spots and the prevalence of hurricanes in the Indian Ocean was the first phenomenon which was cited as a proof that such influence is traceable, and the statistics brought forward appeared to confirm the idea. The periodicity of rainfall was the next subject studied, and as an outcome of the changes in rainfall distribution the recurrence of famines has furnished the text for numerous reports and pamphlets. Another subject dealt with has been temperature, but as to this one set of investigators holds that years of sun-spot frequency correspond to years of excessive heat, while another set maintains that they correspond to years of excessive cold!

This discordance has been somewhat allayed by the suggestion that the causes which produce heat in one region produce cold in another. On the whole, however, it may be said that the precise mode in which the sun exercises his action on our atmosphere has not as yet been explained, and as far as the climate of Western Europe is concerned, the warmest adherents of sun-spot influence must admit that observations of the condition of the sun's surface cannot as yet be depended on as a sound basis for prophecy of coming weather.

That this assertion cannot well be disputed appears from the figures which follow:—

Winter Half-Year.

	Temperature. °	No. of sun-spots.
1876–7	43·7	13
1877–8	43·4	8
1878–9	39·3	3
1879–80	41·4	24
1880–1	40·0	44
1881–2	43·7	64
1882–3	41·8	74

The first column gives the mean temperature of the entire United Kingdom for the six months October—March, for the last seven years, and the second gives the number of sun-spots observed at Kew during the same period.

No approach to concordance is traceable between the two columns of figures.

If we go further afield and compare the general temperature of the globe, at least the closest approximation to it which is attainable, with the sun-spot curve for the thirty-five years ending with 1875, as has been done by Dr. Köppen,† we see that though for some part of the time some of the temperature curves appear to agree with the curve of sun-spots, the accordance in one hemisphere is associated with a striking discordance in the other.

The figures which I have cited therefore support the statement that the precise nature of the relation between what we may call solar and terrestrial weather has not as yet been demonstrated.

As regards the whole question of prediction of the seasons, either by sun-spots or by any other means, the same author, Dr. Köppen, has published several papers "On Protracted Periods of Weather," devoting his attention especially to severe winters, and he gives the following summary of his results.*

"The main feature of the entire investigation has been to prove that, for certain intervals, strongly marked periodical influences make their appearance and then vanish entirely, at times being replaced by others of a totally different character. No law has as yet been discovered for these changes, and so the outcome of the inquiry is on the whole negative, and indicates that all forecasting of the seasons is the merest guesswork."

We may therefore conclude that at the present date there is no immediate prospect of any one being able to state what the character of a future season will be, much less to tell a farmer in spring what crops he should put in with the prospect of a favourable period for the harvest.

I next come to the subject of daily forecasting, a branch of the work of all Meteorological Institutes, which has grown up in Europe within the last ten years. It has really been forced upon meteorologists by the demand of the public to see in the newspapers some statement as to probable weather.

The brilliant successes achieved in this line by the Chief Signal Office at Washington have attracted general notice, and the public of every nation in Europe has expected that their own offices shall do as much for them as that of Washington does for the States of the Union.

The public has, however, naturally forgotten to take into consideration several most important advantages which the Signal Office enjoys over its compeers. Firstly, an extensive continent from which to gather its reports, with one language and one telegraphic system; secondly, a military organization, which ensures due training and proper subordination of the employés to their chiefs; and thirdly and finally, a most liberal supply of funds.

In all these particulars European systems fall far behind that of the United States. Our continent is not large, and it is cut up by inland seas like the Mediterranean and the Baltic, while for us, in these islands the ocean lies to the westward, and from that we can at present gather no reports.

Moreover, the difference of languages and habits between the different states has been found, hitherto, to present insuperable difficulties to the introduction of an absolutely uniform system of reporting.

To take one instance of the difficulty of organizing weather reports in Europe, information as to the state of Sea Disturbance on our shores is justly considered one of the most important observations for our coast observers, but when we came to devise an international code for reporting, we found that inland organizations, such as that of Austria, objected to setting apart any space in the code for such, to them, uninteresting details.

My audience will therefore see that it is not easy for us Europeans to devise a system of weather reporting which shall meet with universal acceptance.

Again, supposing that the code were satisfactorily arranged as regards the reports of instrumental observations, it is found to be practically impossible to organize a system of notices of the general appearance of the sky and the weather, in fact, of the very indications which are the most valuable of all to the skilled weather watcher.

* Read Friday, May 4, 1883.

† 'Zeitschrift der österreichischen meteorologischen Gesellschaft,' Bd. xvi., p. 149.

* *Ibid.*, p. 196.

Here is the crowning defect of all centralized weather services like our own; the forecaster, situated at a distance of some hundred miles from his most important stations, has to draw his conclusions at second hand, from information at best scanty for each station, frequently unpunctual in its arrival, and also at times entirely deficient at the most critical moment, owing to interruptions in telegraphic communication during stormy weather.

The only practical mode of partially overcoming this difficulty of excessive centralization, would entail very considerable expense. It would be the maintenance in the chief centres of population, of local offices, charged with the preparation of forecasts for their own special neighbourhoods, and I fear that neither the Government nor the local authorities would give money for such an experiment.

No serious attempt at local forecasting is made in Europe, except by one German newspaper, the *Magdeburger Zeitung*, for the scheme started in France by Leverrier shortly before his death, of local forecasting by experts appointed by the Communal Authorities, was speedily brought to a stop after his death by a demand from the French Postal Authorities for the repayment of the expense of telegraphy.

We are thus obliged to forecast for the whole country, and as the various portions of these inlands are variously circumstanced as regards proximity to the sea, and as to the mountainous or flat character of their surface, an attempt has been made to group the counties together into a series of districts, the boundaries of which are determined by the general character of the agriculture most developed within them. Thus the western districts are mainly grass producing, while the eastern are corn producing.

This division is necessarily more or less of an arbitrary nature, as the separation between a grazing and an arable region is not a hard and fast line, and of course a driving shower does not cease to fall on crossing a county boundary. But supposing a forecast is drawn up for any one district, it is necessarily limited by the exigencies of telegraphy to a very few words, and it is simply impossible to frame it so as to be correct for the whole of the district. If there is a range of hills crossing the country, the wind which produces rain on the weather slope of the ridge brings dry weather to its lee side. This is a consequence of the well-known principle, that air forced to rise over an obstacle like a hill, is cooled at the rate of about 1° F. for every 300 feet, and is also expanded by the pressure on it being reduced. Both of these actions reduce its capacity for containing moisture in the state of vapour, and rain is produced as the air ascends. Once it has crossed the ridge the reverse action takes place, the air is heated and compressed by descent. It thus becomes capable of containing more moisture, and is felt as a warm and dry wind.

To give an instance of this action on a somewhat large scale, I may cite the district of Elgin and Nairnshire, on the south coast of the Moray Firth. This comparatively flat area is bounded on the south and south-east by the Grampians, and on the west by the hills of Inverness-shire and Rossshire, and all the air from the south and west has had to travel up a series of successive hill sides on its passage from the Atlantic. The result is, that the region I have named has a rainfall not more than one half that of the upper valleys of the Grampians, and yet it is situated in the same district for forecasting. Such is the exceptionally dry character of this strip of coast, that one summer a friend of mine who has a fishing on the Spey told me that for some weeks while the river was in spate, showing that rain fell on the hills, and the fishermen out in the Firth had rain almost every night, not a drop fell at Nairn.

My hearers will, therefore, perceive that the same wording will not suit a whole district, unless it be judiciously phrased so as to bear more than one interpretation.

The figures which I give in Table I. are obtained in a very general way; the forecast for the district is tested by as many reports from that district as are available. This mode, therefore, gives a higher figure for correctness than would be obtained by testing them for a single place.

The second series of figures, in Table II., however, are obtained by a different method, and one which is comparatively free from the objection just stated, as the observers who furnish the data are quite independent of the office, and the forecast is tested by the weather they themselves experience.

Table I. Forecasts at 6 p.m. appearing next morning.

These latter are the results of the Hay Harvest Forecasts, a system which has been in operation for the past four years. Forecasts drawn at 4 p.m. are sent daily for a month to a number of gentlemen, largely interested in farming in various parts of the country, on the conditions that they disseminate the information in their immediate neighbourhoods, and that they keep and send to us a careful comparison of the forecasts with the weather. The general average of the whole agrees sufficiently closely with that determined by the office from its own data.

I find on inquiry, from all the European offices which issue forecasts, that the percentages of success which they claim officially are almost identical with that shown on the diagrams. They are on the whole about 80, but no one is really contented with the results. The critics of foreign forecasts are just as severe on their own systems as the writers of newspaper letters are on us over here, and as one of my correspondents, the gentleman who manages the Magdeburg office, remarks, those who are least content are the forecasters themselves, though naturally they do not publish their dissatisfaction.

To give one illustration, out of many, of the difficulty of our task in England, the same gentleman whom I have just quoted says: "Our greatest trouble is the lateness of arrival of the English telegrams, and, without news from England, no one in Germany can dream of forecasting." Now we, in these islands, as is so often said, can apparently never hope for daily telegraphic news from signal ships in the Atlantic, so that ocean must keep its wonted silence, and our forecasting must be even more hazardous that that of our German neighbours.

Another development of forecasting, and in fact its earliest form, the desire to carry out which gave rise to the whole system of weather telegraphy, and as a result of the latter, to the science of Modern Meteorology, is the issue of Storm Warnings. These were instituted in this country by FitzRoy, in 1866. They were temporarily suspended at Christmas 1866, and resumed a year later, and the diagram gives the average results for the entire United Kingdom, from the year 1870, being the first year for which the figures were regularly submitted to Parliament. The interval of twelve years divides itself naturally into two periods of equal length, the break between which happens so coincide with the institution of an evening, in addition to the afternoon service of reports.

This was carried on, in the first instsnce, at the sole cost of the *Times* newspaper, and in order to furnish materials for drawing the chart in its morning issue, and it is only within the last three years that the expense of this part of our work has been borne by the Government.

The figures show at the first glance an improvement of 8 per cent. in the first column, and this is a considerable advance, but my audience must not take away the idea that if the receipt of four hours' later intelligence raises the percentage of success, we might anticipate the possibility of warning the coasts for all storms, if the reporting hours were extended to midnight, or the service were even continuous.

The extension of the reporting service would enable us in London to know what was taking place on the coasts far better than we do, but we could not impart our knowledge to those whom we wish to benefit. Practically, storm warnings must be issued before sundown, for no port at present will bear the expense of maintaining lamps for night signals. If we allow an hour or so for the warning message to reach the distant stations, and most of them take much longer than that, we see that in winter a warning to a Scotch port must leave London at 2 p.m. to be in time to be communicated by signal. Warnings issued at 7 p.m. rarely come to the fisherman's knowledge till next morning, even if they should reach the telegraph station before that office closes for the night.

Accordingly the figures in the table give a somewhat too favourable idea of our real success in warning.

	Warnings justified		Warnings not justified.	Warnings		Warnings issued in error.
	by Gales.	by Strong Winds.		Late.	Partially late.	
1870–5	47·6	26·8	18·4	1·5	3·8	1·9
1876–81	56·4	23·5	15·8	0·8	3·1	0·3
1870–81	52·0	25·1	17·1	1·2	3·5	1·1

The diagram also does not show the storms which have been missed. Of these there are instances every year. That of October 23–4, 1882, was a most striking case. The storm came on so suddenly, not setting in at any station before midnight, and raging with full fury at 8 a.m., that with our present knowledge it appears to have been impossible to have caught it.

It would take me too long were I to continue this subject, and I would only impress upon my hearers that accidents must happen, like that of October last, and that we must only not let them discourage us, and do our honest best.

The practical result of our forecasting of weather is that while we are generally fairly correct as to the direction and force of wind, we are most liable to fail in predicting rain, especially as to its amount. In fact, not only we, but every Meteorological Office in Europe, have to confess inability to foretell rain, *quantitatively*, to say whether the rain expected to fall will be only slight, or a deluge. In no single case have exceptionally heavy falls, either local, like thunderstorms, or general rains, been foretold. I take as instances, the rain of April 13, 1878, in London, which burst so many sewers; the hail storm at Richmond, August 3, 1879, which will long be remembered in Kew Gardens; or lastly, the snow storm of January 18, 1881.

These failures are very serious defects in practice, and apparently are in great measure attributable to our own ignorance of the conditions of the upper strata of the atmosphere.

Attempts have been made in various directions to organize systems of upper strata observations. These may be classified under three heads, *Personal*, *Mechanical*, and *Optical*.

By *personal observations*, I mean those made on mountain stations cr in balloon ascents.

Of mountain stations we have not yet had a fair trial in these islands, for no mountain observatory, deserving the name, has yet been built. The Scottish Meteorological Society are endeavouring, with great zeal and considerable success, to raise funds to build and maintain a station on Ben Nevis, the highest spot in the United Kingdom, and to place it in telegraphic connection with Fort William, and so with the postal telegraph wires in general, but hitherto all that has been done is that the observer, Mr. C. L. Wragge, has with a most praiseworthy exertion of energy, and in the face of great difficulties, climbed the 4000 feet before 9 a.m. *daily* for four and a half months in 1881, and for five months in 1882. To give an idea of what he occasionally experienced, I may quote his words in a letter of November 1, 1882, printed in *Nature*:—"The track was snowed up, and it was necessary to force a way through great banks and drifts of snow. The average depth was 2 feet; once we got off our course in the blackness of thick cloud-fog, and trackless snow."

Mr. Wragge, on each occasion, as soon as he reached Fort William on his return, generally about 3 p.m., sent a telegram to us in Londan. This never arrived before 5 p.m., so that it was practically useless for all forecasting or storm warning on the day on which the observation was made. We must therefore reserve our judgment as to the usefulness of the proposed station until it is in efficient working order, and the observations can reach us more promptly.

As regards balloons the observations are necessarily sporadic and uncertain. No ascent is possible if the wind is at all strong. No captive ascent can attain any great height, and no free ascent can be made with a certainty of being able to send off a telegraphic message when the observer reaches *terra firma*, for he may come down miles from a telegraph station.

The admitted impractibility of guiding a balloon, and the liability to accidents, in the case of a squall, either on leaving the ground or on returning to it, of both of which recent instances, one unfortunately fatal, are on record, render it unadvisable to rest any hopes of permanently extending our knowledge of the upper currents of the atmosphere by the aid of aeronauts. Moreover, they can never give us reports at a fixed hour every day for the purpose of completing our charts.

The *mechanical* method of observation may be soon dismissed: it consists either in sending up instruments in small captive balloons, or attached to kites, or in placing them on elevated peaks. In all these cases the registration is to be effected by means of electricity. The apparatus devised by Sir W. Siemens, and lent by him to the Meteorological Society, has been in operation on Boston church tower for several months, and has worked well, and the same may be said of Olland's telemeteorograph on the tower of Utrecht Cathedral, but the obtaining of records from such an elevation as can be secured on the loftiest buildings, is not obtaining them from the upper currents of the air, and we have yet to prove the practicability of raising an electric thermometer to a height of, say, 2000 feet, and maintaining it there in all ordinary weathers, before we can say that much is to be expected from mechanical upper current observation.

Lastly, we come to *optical* modes of observing the condition of the air above us. These are the only ones which as yet give us much encouragement, and of them I shall only mention two. Spectroscopy and cirrus cloud observations.

The former has an enthusiastic advocate in Professor Piazzi Smyth, whose repeated letters to the newspapers have at least attracted the notice of many who have not seen his copiously illustrated work on the subject, 'Madeira Spectroscopic.' Professor Smyth maintains that by observations of his rain band in the spectrum, he can form an accurate estimate of the amount of moisture suspended in the air. This belief of his is not as yet, however, accepted as an article of faith by meteorologists at large, and even, if it were, it still remains to be proved how much warning of coming rain such phenomena will afford. If they only give it for a few hours, the advantage they present to us is not very material.

Under any circumstances there are great obstacles to the general introduction of spectroscopic observations at telegraphic reporting stations. The instruments are comparatively costly, and their use requires more skill and delicacy of handling than we can expect from men of the rank of our ordinary telegraphic reporters.

Lastly, we come to the observation of the clouds, especially of the upper clouds, which has been of late almost reduced to a science, mainly by the labours of the Rev. W. Clement Ley in this country, and of Professor H. Hildebrandsson, of Upsala, in Sweden, around whom a knot of observers are gathering. Mr. Ley is the most enthusiastic, and also by far the most experienced of the authorities upon the subject, and he said of himself in a lecture delivered a few years ago, that he had spent one-twelfth part of his waking existence in watching cloud motion. What he advances therefore must be received with due respect.

For his own district, the Midlands, he claims to be almost infallible as regards weather, when he can secure an observation, and from our experience of his telegrams to us his announcements for the country in general are frequently astonishingly correct. In few words, the principle which he applies is the motion of the highest stratum of clouds, the "cirrus" of Howard and its relatives. He has shown that the various motions of these clouds can be explained by the view that the air slowly whirls out of a cyclonic area in the upper strata, in directions opposite to those of the wind motion at the earth's surface.

Thus, for instance, when pressure is higher over France or Germany than it is in Scotland, a motion of cirrus from north-west indicates the existence of a depression situated to the west of us, and as that depression advances on us the first wind we shall feel will be South or South-east, certainly not North-west.

Similar rules have been laid down for cirrus motion in other azimuths, and from its rate conclusions may be drawn as to the motion of the depression whence it takes its rise.

This seems exceedingly promising, but now comes the other side of the picture. Mr. Ley himself admits that the faculty of cloud observing is incommunicable by simple teaching. The motions of these clouds are so gradual, and are apparently so liable to be confounded with the motions of other and lower strata, that a great exercise of judgment is requisite before an opinion is pronounced.

Supposing, even, we have only one stratum to deal with, the head must be kept immovable during the period of observation, and the motion of the cloud across or past a fixed object, like a chimney, watched. Lastly, the observations cannot be always taken at fixed hours, at the fixed observing epochs, but must be made whenever opportunity offers. The observers, therefore, must have abundance of leisure, and that is a commodity hard to meet with in these busy times.

What is then the general conclusion we can draw as to weather knowledge and its prospects in 1883? I have endeavoured to show you that *weather knowledge* is practically *weather prediction*, and that, for the seasons, in Europe at least, no trustworthy basis for prediction has as yet been established.

For the daily forecasting of weather much has been effected, but much more remains to be done, and the most important advance we can make is in the direction of training observers in the difficult art of upper cloud observation, the most promising field of study at present.

The inquiry into Atlantic weather which is now being carried on in our Office, and which enables us to prepare daily weather maps of the ocean with nearly four hundred observations on each, will, it is hoped, throw light on how and where some of the storms which visit us take their rise, but it will certainly show what actual condition over the ocean accompanied each manifestation and movement of cirriform clouds at our stations, and will thus afford data for laying down rules to determine the position and track of a storm-centre before it reaches our coasts.

Cirrus observations are in fact the only practical means we have of, so to speak, annulling our insular and isolated position, and of extending our outposts over the Atlantic.

SOCIETY OF ARTS.

Solid and Liquid Illuminating Agents.*

BY LEOPOLD FIELD, F.C.S.

Lecture V.

Quitting the consideration of those substances which are yielded to us by the perennially renewed productiveness of the modern earth, we came to a class of luminants which may be considered as treasures from the catacombs of the dead world—from the storehouses of the young sun's heat, garnered in a newly verdant vegetation. You will recollect that, in the first lecture, I drew your attention to a great class of bodies which are now included under the common designation of paraffins, and which include such familiar substances as naphtha, bitumen, asphalt, petroleum, benzene, and paraffin proper. Of the origin of these substances science affords us such ambiguous teaching, that it remains still open to anyone furnished with certain data to form his own theory on the subject. I have told you that marsh gas is a concomitant of slow organic decomposition, especially of vegetals. Now, as in the vicinity of all great sources of mineral luminants gaseous jets are of very common occurrence, it is not unreasonable to suppose that once living organisms are the primary sources of the paraffins. Yet it will not do to adopt this theory too readily, as certain warrantable men have hazarded their opinions in a contrary direction. For instance, Berthelot—than whom none have a better right to speak—suggests the following hypothesis. Acting on the supposition that

* Cantor Lectures: Reprinted from the *Journal of the Society of Arts*.

Daubrée's theory of the presence of free alkalies in the earth's interior is correct, he presumes that the carbonic acid with which the earth is impregnated comes into contact with metallic sodium, forming acetylides. Steam, acting on these, would generate acetylene, and under the circumstances of extreme heat and pressure, we might well presume that bituminous products could be aggregated, as we know that hydrogen acting upon acetylene produces olefiant gas, or ethylene. Thus we might presume that paraffins have been formed by purely mineral combinations, especially as we know that the reactions presumed to have there taken place can be exhibited with tolerable ease on the lecture table. We also know that hydrocarbons have a great tendency to molecular condensation. But the objection to this (and it is a very serious one) is, that the conditions of such extreme subterraneous heat and pressure can only obtain far below the strata in which the last vestiges of petroleum are found. We must, I think, conform to the organic theory, and grant further that the sources of petroleum are various of their kind. For instance, Illinois limestone is found to be composed of corals, in each cell of which a small particle of oil is hermetically sealed up, for which it is impossible to account, otherwise than by supposing it to be the result of the decomposition of the animalcule under the pressure of its own gases. Professor Peckham believes petroleum to be the primary product of decomposition of animal and vegetal organisms, and that the viscid and solid compounds, as bitumen and asphalt, are the results of inspissation. In Ritchie County, West Virginia, a vertical seam of asphalt cuts a horizontal coal seam in yellow sandstone, which is supposed to be the solidified distillate of petroleum wells below, especially as oil and gas springs abound in the neighbourhood. Petroleum is also found in the West of Canada, where there are no coal measures at all; this invalidates the theory of petroleum being always the product of distillation of coal by subterraneous heat, although, as we shall see afterwards, there are good grounds for supposing this to be probable in some cases. Petroleum exists in strata of all ages, from the lowest Silurian to the Tertiary. It has even been found in the Laurentian, which was supposed to be destitute of organisms until the discovery of the eozöon. In fossil shells it is frequently found. Orthocerata sometimes hold several ounces. In Western Pennsylvania, oil is found *below* the coal strata. In the Niagara limestone of Ohio, petroleum occurs, thick and tarry, in the cavities of shells. Ohio slate contains bitumen in thin plates, and oil springs are found in the bottom layers of sandstone overlying slate. As the animal remains in slate are too few to account for the quantity of bitumen found, we must suppose that in this case it is the product of decomposition of seaweed spores and drift. That tarry matter is sometimes considerably present in slate is evident, from the fact that the piers of the suspension bridge at Cincinnati, which are made of slate, drip with oil when the sun plays upon them. From these instances given of the heterogeneous sources of petroleum, you may judge how difficult it is to form any theory of formation which shall embrace all conditions in its hypotheses. It is generally conceded that the formation of coal is based on a different action, petroleum never having been found under such circumstances as to leave no doubt of its derivation from the decomposition of wood. The chemistry of petroleum is obscure, for we cannot tell what its composition is before distilling; and yet, on the other hand, it is impossible to arrive at any ideas concerning its constitution without having recourse to that process. The composition of petroleum varies considerably, which points to the varied nature of its sources. For instance, in rocks of the Tertiary age, which contain fossil remains of complex organisms, we find a petroleum rich in nitrogen, and of putrescent odour, as the petroleum from Miocene Coast Range, South California. Further, petroleum, found in such rocks as contain low organisms, is almost devoid of nitrogen.

One noteworthy fact must not be overlooked; that the incline of the various strata has much to do with the way in which petroleum is accumulated. It may be stated, as a general rule, that petroleum wells are only to be found at the bottom of inclined strata. Thus, in Canada, where the layers are horizontal, very little petroleum is found; whereas in Pennsylvania and Ohio, the oil-bearing rocks, which are just below the surface in Canada, dip beneath the Devonian and Silurian, which furnish reservoirs for the oil, condensing above and percolating downwards. In this case, the petroleum may be presumed to be the product of subterranean distillation; in proof of which may be adduced the vast evolution of gas at such places.

In its natural condition, petroleum is too dark and impure for any regular employment. To those circumstances, no doubt, it is due that the great uses of this wonderful oil remained so long unknown. The aborigines in North America knew it under the name of Seneca oil. They used it with pigments to paint their skins, and also in their religious rites, which circumstance is mentioned by the commander of Fort Duquesne, in 1750. Seneca oil was sold largely as a medicine, being, no doubt, exceeding efficacious in cutaneous disorders. Later on, we find the Dutch druggists vending "Haarlem oil," also a petroleum. The gaseous form was used first to evaporate sea-water for salt. This was done nearly forty years ago at Malta, Morgan County.

I will dismiss the gaseous petroleums with a few brief remarks, as they have not much to do with illuminating. The principal gas wells are in Butler County, and the two largest wells are the Burns and Delameter. The latter well is at very high pressure. The tube is $5\frac{5}{8}$ inches in the bore, and the gas issues from this at a pressure of 100 lbs. to the square inch. It drives a huge engine, and the gas issuing from the escape pipe, lighted, gives a flame nearly forty feet high. After being conveyed through twenty-eight miles of pipe (6-in.) to Pittsburg, it is yet at sufficient pressure to drive powerful machinery. For twelve years gas has been furnished with undiminished vigour. The amount of gas evolved may be roughly taken as 1,000,000 cubic feet per hour, which is equivalent to 3000 tons daily. Its light is equal to that of seven and a half candles, and it gives, weight by weight, 25 per cent. more than bitumen. Its composition averages 82 per cent. marsh gas, 10 per cent. ethylene, and $7\frac{1}{2}$ per cent. hydrogen, with traces of various other gases.

The history of the discovery of petroleum in quantity, and of the rise of the industry, is very interesting. The first notice of petroleum, as an illuminating agent, was given by Dr. Hildreth, in 1819. He alludes to it as being burnt in workshops and factories. Thirty-five years elapsed since his writing before the Pennsylvania Rock Oil Company was formed, in 1854, for the purpose of gathering oil in Oil Creek, Pennsylvania. Their process of collecting was a slow one, inasmuch as it consisted in drawing cloths over the surface of the naphthalized ground, which were squeezed into tubs. But in 1858, Colonel Drake, the superintendent of that company, conceived the idea of boring for petroleum, after the manner of an artesian well. Disregarding the ridicule which naturally fell to his share, his hopes were realized in August, 1859, and he began to pump oil at the rate of 400 gallons a day. The excitement was tremendous. Land in the vicinity increased a thousandfold in value, and "derricks" sprang up like mushrooms. Well after well was opened, and a corresponding number of fortunes made. But this enormous supply soon surfeited the market, as the condition of the petroleum had not been perfected sufficiently to create an adequate demand. In 1861, the price had sunk to 25 cents per barrel; whereas before it had realized 55 cents per gallon. The rapidity with which the production took place was such that, in 1860, the quantity was 50,000 barrels; in 1865, 2,500,000; and in 1873, nearly 10,000,000 barrels. At present, the oil region of Pennsylvania covers 400 square miles, on which are established 3000 working mills. If you will refer to what I said about the inclination of strata being requisite for the formation of oil wells, you will understand that, as a matter of course, the best wells lie deepest, and a large amount of very solid slate rock and sand has to be penetrated before "striking oil." The first step in prospecting is the driving of iron pipes, six inches in diameter, into the earth with a ram, until the solid rock is reached. This has to be bored through, and is perhaps one hundred feet thick, usually slate. Then comes a layer of sand, which is rapidly traversed; then another layer of rock, and so through, sometimes, four or five alternations of sand and slate, until a depth of five hundred feet is reached, although occasionally the oil lies much nearer the surface. The tube is then secured, and the oil pumped. Few oil companies put down their wells themselves now, as this forms a separate branch of labour. Organized companies exist, who contract to bore at so much per foot. The average depth is about two hundred feet. A great desideratum of the oil seeker is to find a flowing well, which, next to gas-wells, are the most astonishing phenomena of this remarkable industry. The first flowing well struck was on the farm of a man named Funk, and is known as the Funk well. In June, 1861, the boring commenced, but no sooner had the pipe touched the oil, than it commenced flowing in great volume at the rate of 250 barrels a day. In spite of all prophecies as to its speedy cessation, the Funk well flowed fifteen months, and the lucky owner cleared his "pile." Meanwhile, on a neighbouring farm, the "Phillips" well had burst forth, yielding over 2000 barrels, daily. Thereupon the "Empire" well commenced spouting at the portentous rate of 4000 barrels per diem. This was rather a surfeit of riches, inasmuch that no possible demand could be expected to secure so vast a supply; and the oil, when once it commenced to flow, could by no possibility be stopped. The price fell to 20 cents per barrel; then 15 cents; then 10 cents; at last the barrel itself was of greater value than the oil, and could not be procured. Finally, all the coopers in the country could not supply barrels at the rate the oil was produced; in vain they dammed it; the oil overflowed the creek, and covered the water for miles with a nauseous film. At length, by building enormous tanks, they stored the oil until the market should recover from its surfeit. For nearly a year this enormous supply continued. There are some flowing wells which do not give a continuous yield. Some cease for an hour, some for a week, and others even for several months, then continue at their usual rate. By the perfection of apparatus for its refinement and consumption, supply and demand have equilibrized, and the petroleum industry is now as standard as that of any other mineral. The average total yield of crude oil is 75,000 barrels per diem from over 18,000 wells. The number of barrels of refined oil exported last year from New York was 6,614,865, at a price of from 6¾ cents to 8¾ cents per gallon.

Petroleum, as it flows from the pump, is valueless for any save the crudest purposes, being a mixture of solid paraffins and heavy oils with others almost gaseous. To render it useful, it has to be distilled. The process of purification so closely resembles that employed in the treatment of the oil from shale, that one description will suffice for both, and will follow in due course. I will here give the different products of petroleum in their order, as they differ somewhat from those of shale oil:—

	Specific Gravity.	Boiling point.	Use.
Cymogen (butane)	·578-·603	0·° C.	Refrigerating.
Rhigolene	·603-·629	18·°	Anæsthesia.
Gasolene	·629-·673	—	Naphthalizing gas, and in air gas.
Naphtha	·673-·723	—	As a solvent, also in oilcloths, etc., street lamps.
Benzine	·723-·744	—	As a solvent, and in paints, etc.
Kerosene	·744-·838	—	Lamp oil.
Paraffin oil	·838-·906	—	Lubricating.

The products then grow viscid, and it is from these that the substance called "vaseline" is made.

Owing to the great danger of burning in lamps such petroleum as has not been freed from the lighter hydrocarbons (as only too emphatically attested by many mournful accidents), the testing of petroleum oil has become a Government office, and much labour and research have been spent in devising the best means for ascertaining the precise point at which the oil "flashes." By flashing point, we understand the degree of temperature at which an inflammable vapour is given off; and, however heavy the bulk of the oil may be, if it contain any proportion, however small, of the lighter oil, it will ignite at the flashing point of the latter. There are two chief systems of testing: the one being known as the open test, which, from its simplicity, was much affected in the mining districts. I have here some petroleum in a tin vessel, which I place in this beaker of hot water, wherein is a thermometer. Passing this taper over the surface of the oil, I observe a blue flash—in fact, you see the petroleum has taken fire, and is blazing furiously. I pour a few drops of the blazing oil in water, and you will notice that, instead of extinguishing it, this process animates the flame. But this method is far too rough and ready, and contains too many sources of error, to be adopted where such vital interests are at stake. Without entering into the reasons which have led our Government to adopt the instrument devised by Sir Frederick Abel for the accurate determination of the flashing point of light oils, I will give you a brief explanation of the apparatus itself. Its main objects are, to secure a uniform rate of heat and light, freedom from all air currents, and absolutely equal and constant conditions of testing. This copper vessel, six inches in diameter and six inches deep, surrounded by an air chamber, is full of water, which is heated by a spirit lamp below. The receptacle for the oil is two inches in diameter, and fits into the lid of the outer vessel, being immersed in the water to the depth of one and a half inch. This is also surrounded by an air chamber, which conveys the heat from the water to the oil at a slow and uniform rate. The thermometer, with its bulb in the water, is fixed on the lid of the water vessel, and another thermometer enters the oil. Before commencing the experiment, the water is heated to 130° Fahr. precisely; after which the increase in temperature from the lamp proceeds at the uniform rate of two degrees per minute. The lid of the oil cover is a tiny lamp, the flame of which, being no larger than a pea, can hardly be visible to you at this distance. By a sliding inclined plane, the nozzle of this lamp is lowered into the oil receptacle simultaneously with the withdrawal of the slide, while the proportion of air in the chamber is kept constant by this little hole in the side, which opens and shuts concurrently with that in the top. Every time an opening and shutting takes place, a mixture of oil vapour and air comes into contact with the flame. The time during which the slide is opened is determined exactly by the beats of a pendulum. At a certain point, a blue flash fills the interior of the oil cup, and the temperature of the thermometer denotes the flashing point of the oil. According to the open test, the flashing point decreed as the standard of safety by the Act of 1871, was 100° Fahr., but Sir Frederick Abel, after a careful investigation of the conduct of oil which had been tested under those regulations, showed that, with his close test, the flashing point was 27° below that obtained by even the most careful open test. He, therefore, recommended 73° as the standard of safety with his apparatus, and this has been adopted by the Government. What I have said of petroleum refers also in a great measure to paraffin oil; indeed, the similitude between these two sources is very considerable; the difference lying mainly in the relative proportion of olefins and paraffins which they contain.

At this juncture we will quit petroleum for paraffin, and apply ourselves to a cursory study of this important industry. I mentioned Reichenbach as having obtained paraffin, in 1830, from wood tar. Dr. Christison, of Edinburgh, however, extracted the same substance from Rangoon tar almost simultaneously and independently. In 1835, Dumas, the great French chemist, obtained the wax from coal tar, but it did not rise beyond the status of a chemical curiosity until 1850. In fact, in that year, Professor Abel sent my father, then vice-consul in Chili, a little specimen of a few grains in a tube, as one of the curiosities of the day. To the late Dr. James Young belongs the honour of creating the paraffin industry. In 1848, his attention was called by Dr. Lyon Playfair to the presence of petroleum on the top of a coal seam at Alfreton, in Derbyshire. Mr. Young at once started his operations, and succeeded in extracting a considerable quantity of paraffin, a light burning oil, and a heavy lubricating grease. This supply soon drying up he sought other fields for his enterprise. He theorized that the petroleum had been formed by the action of heat upon the coal, and that the vapour, passing through the sandstone, had become condensed into liquid. Whether this theory was right or wrong does not matter; his results were eminently satisfactory. In 1850, he took out his celebrated patent, which, simple though its provisions were, defied all attempts at infringement, which were numerous. You are aware that, if heat be applied strongly and suddenly to coal, nearly all the volatile portion comes over as gas, the residue being tar, from which again a great number of remarkable and valuable substances, such as benzol, anilin, anthracene and phenol, are obtained. But Young discovered that, by increasing the temperature gradually, and never allowing it to rise above 600° Fahr., a thick oil distils over, which yields paraffin wax and burning and lubricating oils. I must, however, mention the invention of Rees Reece, which immediately preceded that of Young, and referred to treating peat. He first of all distils the peat tolerably rapidly in an apparatus. The tar thus obtained he distils at as low a temperature as possible, collecting half the products in one vessel, and distilling over the remaining half in a second receiver. In this second distillate he finds paraffin crystals and paraffin liquid. The crystals are separated by filtration through hair-sieves and pressure after the manner of stearin. The paraffin thus obtained is distilled, moulded, and hot-pressed. I have on the table some magnificent specimens of every step of this process, kindly lent me by Professor Bloxam, of King's College. You see here the peat, which may be considered as the first step in the formation of coal. Here is lignite, or brown coal, extensively used in Germany. This dark thick mass is the first running; this bottle contains the lighter hydrocarbons; this light brown crystalline semi-solid is a mixture of paraffin crystals and oil, and these again are the several refinements of the wax, and the burning and lubricating oils. But the yield from peat is not to be compared with that from shale, which was the substance ultimately fixed upon by Dr. Young as the basis of his process. The first material he used on a large scale was the celebrated Boghead coal, or Torbane Hill mineral. This valuable substance contained 70 per cent. of volatile matter, of which the major proportion was hydrocarbon. A very interesting lawsuit, in 1853, had as its issue whether Torbane Hill mineral could justly be considered as coal. Now, as Mr. Young claims coal in his patent, its validity depended on this delicate question. It was ultimately decided against Mr. Gillespie, who had raised it. But this mineral had but a short though brilliant career, and, since 1862, paraffin oil owns as its only source bituminous shale, which abounds in Linlithgow and Midlothian. At present, the amount of this appears inexhaustible, which compensates to a certain extent for its poverty compared with the Bog-head mineral. Between twenty-two and thirty-eight gallons of crude oil per ton are obtained from shale, which is about one-fourth of the quantity yielded by Bog-head coal. The enormous supply of oil from America, however, causes the English companies to strain every nerve to meet the competition. They are at a considerable disadvantage to start with, inasmuch as petroleum flows from the soil in the same state of purity as the shale oil attains after having undergone distillation.

I will now give a sketch of the method at present employed in obtaining paraffin from shale. The earliest form of retort, still largely used, is a round or oval cylinder, furnished with a hopper on top. The dimensions are about 2 feet in diameter by 9 feet high. The retort is charged by means of the hopper, and at the bottom it opens into a trough of water, which acts as a luting. The vapours leave the retort at the top, and a current of steam enters the bottom. We will, however, discuss the process as conducted in the Henderson retort. Each chamber contains a set of four retorts 15 feet long, capable of holding 18 cwt. of shale. A platform on the top is provided with rails, on which trollies run to and fro, charged with the shale, which they empty into the retorts. The great advantage of this form of apparatus is the manner in which the shale, by being discharged into the furnace below, is made, by the combustion of the residual carbon, to continue the distillation of the fresh material. The combustion-chamber below receives the spent shale, which is admitted by a trap. The combustion, at first sluggish, is assisted by the admission of the incondensable gases produced in distillation. In order to produce an equable temperature throughout, the flame is never allowed to touch the retorts. The heated gas alone enters the oven, in which the retorts are placed, by means of the flue. By this arrangement the whole of the apparatus is maintained at a temperature of about 800° Fahr., as against 1200° or 1500° in the old retorts. The products of distillation by the two methods, as you see by these two samples, differ considerably in appearance. The new process yields an oil of a bright green colour of about ·870° sp. gr., against this dark pitchy oil of nearly ·890° from the old retorts. The new process gives also $2\frac{1}{2}$ per cent. less refuse and about 2 per cent. more paraffin.* The amount of sulphate of ammonia produced is also very much larger by the new process, owing, no doubt, to the superheated steam employed. This product, at first almost disregarded, is now one of the pivots on which the success or failure of a factory turns. After leaving the retort, the vapour passes through a series of upright pipes fitted into a trough, after the manner employed in the distillation of palm oil; by this means about one-third of the vapours are condensed, the products consisting mainly of ammoniacal liquor, with about 25 per cent. crude oil. The uncondensed portion passes through a tower over which paraffin oil trickles, which takes up a very great proportion of the light vapours. The crude oil, after separating from the ammoniacal liquors, is pumped into a still, and brought to dryness in a current of superheated steam. After passing through a system of condensers, the liquid, which has now assumed a brighter green tint, is received into a suitable vessel. In the retort there remains a very fine pure coke. The oil is next freed from water, and then, by violent agitation with strong sulphuric acid, from the

* See correspondence as to respective merits of new and old systems. *Proceedings of the Institution of Civil Engineers*, vol. lxvi., part iv.

tarry impurities. After two or three such agitations, and subsequent separation of sediment, the oil is treated with a solution of caustic soda, to neutralize the acid, and then with a little warm water, which washes out the residual soda. The amount of acid and soda used depends considerably on the nature of the oil. The effect of this process on the distillate is to reduce its gravity to between ·830 and ·845, it having lost about 15 per cent. in the process of refinement. It is now subjected to fractional distillation. I have here a small apparatus which will, perhaps, explain the process better than words can do to those who are unacquainted with the operation. In this retort there is a mixture of various light and heavy oils. A thermometer is passed through the tube of the retort, which is connected with a glass condenser. As long as any oil of lighter boiling point than the others remains undistilled, the temperature will not rise beyond the boiling point of that oil. While, therefore, the thermometer remains constant, the products of distillation may be presumed to be of one kind. As soon as the light oil is exhausted, the temperature rises until the boiling point of the next lightest oil is reached, after which it will remain constant until the whole of that is distilled, and so on until the distillation is finished. Upon this convenient property the distillation of paraffin oils is based. The first distillate, which is exceedingly light, is set apart for naphtha. Oils of sp. gr. ranging from 770° to 850° are reserved for burning; and distillation is then continued till the liquid in the still has reached a depth of between 12 and 18 inches. The last fraction is very heavy, and contains nearly 30 per cent. of paraffin. The burning oil is purified with repeated washes of acid and soda, and again distilled. The distillate is similarly treated—this time with less acid—and it is then distilled again, the fractions being carefully separated. The specimens on the table will show you the different fractions and their employments. The distillate from ·760° to ·790° is "No. 2 burning oil;" from ·790° to ·806° "No. 1 burning oil;" ·806° to ·820° "lighthouse oil;" while the fractions from 825° to 840° are mixed respectively with No. 1 and No. 2. Various purifications have still to be undergone by No. 1 oil before it assumes the beautiful limpidity which gives it the name of "crystal" oil. The liquid from the coke tower is mixed with the first distillate from the purified oil, heated with acid and soda, and distilled. The runnings from 640° to 660° are set aside as gasoline; from 700° to 720° they are termed naphtha. The names of the various fractional oils from petroleum and shale oil are much the same. I will refer you, therefore to what was said under the former head for the names. In the next lecture, I shall point out the difference in their chemical constitution.

We have now to consider the process of purifying the paraffin scale. The heavy oil obtained from the last stage of the first distillation is crystallized from the oil. The hard scale is that which separates by itself in ordinary weather, and the residual oil from this is subjected to artificial refrigeration, in which process gasoline is largely employed. This yields the soft scale. The separation of the solid from the liquid paraffin is a point of immense importance, and no less the refinement of the solid paraffin from all traces of oil. The former object is attained by repeated refrigerations and filtrations under pressure; the latter by washing the scales repeatedly with naphtha, which keeps the oil in solution and deposits the refined paraffin. Finally the paraffin is agitated with very fine animal charcoal; and upon the selection of this article also much depends. Upon filtration from charcoal the paraffin is run into circular moulds, and, when cool, presents the magnificent appearance which you see in this cake from Messrs. Young's Works. I must here express my obligations to Mr. Fyfe, the manager of that Company, for his discriminating kindness, which has provided me with such numerous and well-chosen specimens. The oil which is pressed from the soft paraffin scale is called "blue" oil, from its peculiar colour; and this, after acidification and treatment with soda, furnishes lubricating oils. The melting point of the best paraffin is about 130° F., ranging down to 100° F., below which it is unsuitable for making into candles. The above is an outline of the manufacture of paraffin, which can only be filled in by reference to the works on the subject. Indeed I have been forestalled in this branch again by Mr. Brunton, who, a short time ago, read a most exhaustive paper on the paraffin industry before the Institution of Civil Engineers. I have reserved the account of the probable constitution of the various forms of paraffin and petroleum, and other points connected therewith, for the final lecture.

Obituary.

Notice has been received of the death of the following:—

On the 2nd of June, Mr. William Willock, Chemist and Druggist, King Street, Kilmarnock. Aged 54 years.

On the 25th of July, Mr. William Williams Mildren, Chemist and Druggist, Caledonian Road, N. Aged 39 years.

On the 28th of July, Mr. Thomas Bourhill Cairns, Chemist and Druggist, Dalkeith. Aged 31 years.

On the 31st of July, Mr. Samuel Gammidge, Pharmaceutical Chemist, Belgrave Gate, Leicester. Aged 54 years. Mr. Gammidge had been a Member of the Pharmaceutical Society since 1853.

On the 10th of August, Mr. John Mather, Chemist and Druggist, Scholes Street, Wigan. Aged 46 years.

On the 16th of August, Mr. Thomas Jackson Palmer, Chemist and Druggist, East Grinstead. Aged 71 years.

On the 19th of August, Mr. Samuel Blackmore Charles Tatam, Chemist and Druggist, King Street, Plymouth. Aged 28 years. Mr. Tatam was an Associate in Business of the Pharmaceutical Society.

On the 20th of August, Mr. Peter Bramwell Drinkwater, Chemist and Druggist, London Road, Manchester. Aged 38 years. Mr. Drinkwater had been a Member of the Pharmaceutical Society since 1878.

On the 22nd of August, Mr. Henry Norman, Chemist and Druggist, St. Peter's Street, Canterbury. Aged 41 years.

On the 23rd of August, Mr. Robert Coulson, Chemist and Druggist, Forest Gate. Aged 72 years,

On the 24th of August, Mr. John Downward, Chemist and Druggist. Market Street, Ulverston. Aged 78 years.

Correspondence.

The Duties and Responsibilities of the Chemist in Cases of Accidental Poisoning.

Sir,—It has long been my desire to draw the attention of your readers to the above subject, and to solicit opinions thereon.

In cases of accidental poisoning chemists are often called upon, and it is really a matter of much difficulty to determine how far chemists ought to proceed before the services of a medical man can be obtained. I do not refer so much to those cases where the poisons are both quick and fatal; in such a case when life is in immediate danger, no professional etiquette would be likely to prevent a chemist from using all the means in his power to save the life of a fellow-creature. But there are what might be called the minor cases of poisoning, where small quantities of salt of sorrel, salt of tartar, nitre, turpentine, ammonia, and such like are swallowed, and the result, although not immediate, may be serious enough. The most recent under my observation was an instance of taking salt of sorrel for rochelle salts. The drug was obtained at my own pharmacy, and although I used every means to obviate danger, I fear paterfamilias has not forgiven me because I did not go to the house and see the victim. The case is as follows: I, like most suburban chemists, am well used to washer-women coming direct from the wash-tub, with the soap still frothing on their hands, for salt of sorrel. One morning last week, a woman of said type and apparently from the wash-tub came to my shop and asked for a penny-worth of "some sort of salt." I at once concluded from her appearance that it was the usual order for salt of sorrel, and having mentioned that name, she answered, "Yes." I weighed out the quantity, and when labelling I always make a point of repeating the name, and the word poison, to be careful. My customer, whose tongue betrayed the isle from which she came, passed out without saying anything to assure me of her having heard my word of warning. In about half an hour she returned in a great state of excitement to tell me I had given her poison, and that she had given it in water to the lady for whom she was working, I at once gave her some prepared chalk to be administered in some water or milk, and to be followed by a mustard emetic. I also told her to call in the doctor. I said there would be no immediate danger, if she gave the chalk and emetic, as directed. The patient fortunately vomited shortly after, and on the arrival of the doctor, some hours after, he found the patient out of danger, but was surprised to learn that I (the chemist) had not gone to see the antidotes administered. I consider I did all that I would have ventured to do, without leaving the shop, and surely, the administration of the chalk and mustard might be safely left with the members of the household. As a natural sequence I was visited in the evening by two men, who lectured me most unreasonably; not only did they accuse me of a direct blunder, but based a furious attack upon the remark of the doctor, "that he (the doctor) was surprised the chemist did not attend!" I may mention that I was never asked or sent for, and had no idea where my Hibernian customer had come from. As an instance of the carelessness of some people, I discovered that this woman who was entrusted with the giving of medicine could neither read nor write. The package was distinctly labelled "Salt of Sorrel, Poison."

I shall be glad to hear the opinion of your readers and fellow pharmacists.

Mors.

Visit to Hop Gardens.

Sir,—To-day being the last early closing day of the season, I thought I would stroll through the largest hop garden in the district, and you may judge the size when I say it took me forty minutes to leisurely walk through it. It was a beautiful sight to see the bine covering and hanging from the immense number of poles (which are arranged in threes for greater support), and bearing the hops or strobiles. I have seena lrger, but never before such a uniformly greenish-yellow tint, which, with the darker green leaf and equal distances of the poles, had a beautiful and symmetrical effect. I have noticed a stronger aroma before in passing through a hop garden, but possibly the lack of this may be accounted for by the deficiency of rain of late; the quality seems to be very good this year, and wonderfully abundant. On returning home by another path I came to a hop oast or kiln, and seeing the fires were burning I was curious enough to peep inside the building, which was a large square structure, adjoining it also being a circular building tapering like a small steeple with a rotating ventilator on top.

The foreman kindly offered to show me over it and I gladly availed myself of the opportunity; as hop picking began last Monday (August 27), the process of drying was in full swing.

I was first taken to the upper floor, where were hops lying about in heaps, and was permitted to walk through them by pressing the feet forward so as not to injure the hops. In the centre was a circular hole in the floor, from which was suspended a bag or pocket into which the hops were being pressed ready to be despatched. I must confess the aroma from such a large quantity was not so powerful as I should have anticipated, yet it was very agreeable. From the same floor I ascended four or five steps that led to a large door, which on being opened exposed to view a large dark room (drying room), the floor, made of hair, being covered with hops drying, the warmth and SO_2 which affected the olfactory nerves and also set up throat irritation forcibly reminded me I was bending over a rather large coke and sulphur fire. On descending to the ground floor I was shown the fires, there being three, one for each drying chamber. There was almost an entire absence of SO_2 in any part of the building, except of course the large chambers where the fires were and the drying rooms above them; no doubt the draught carried it towards the ventilators on the top of the building. Seeing a heap of charcoal, I was informed the fires were first lighted with that, and kept up with the coke. I was then taken to the round tower, where was a large circular chamber with "three" coke and sulphur fires, and having a drying chamber above. Outside the building there were numbers of pockets of freshly picked hops, feeling damp, most of them being above the ground on slanting hurdles; these were to undergo the process of drying before the morning. It was dark, being nearly a quarter to eight when I was privileged with an insight into a hop-kiln in use.

Milton, Kent. A. S.

"*Occhio.*"—Your first question we are unable to answer. The physiological and remedial properties of boracic acid are not so well known as might be wished. It was formerly used as a sedative in some disorders of the brain, and it has been used internally for chronic cystitis, diphtheria, and chronic dyspepsia with fetid eructations. Used externally it has an antiseptic action, and it is the principal ingredient in an ointment used by Mr. Lister.

Herbalist.—(1) *Sedum acre.* (2) *Honkeneya Peploides.* (3) *Sedum villosum.* (4) The plant should be sent when in flower. (5) *Iris Pseudacoris.*

Inquirer.—(1) *Galium verum.* (2) *Erodium cicutarium.* (3) *Lychnis vespertina.* (4) *Petasites fragrans.* (5) *Linaria vulgaris.* (6) *Hyperioum perforatum.*

E. J. Cox.—*Bupleurum rotundifolium.*

T. M. C.—*Epilobium parviflorum.*

Junior.—*Menyanthes trifoliata* (Nat. Ord. Gentianaceæ). It is said to produce obscuration of vision, and has been recommended as an anthelmintic and as a bitter tonic when the liver is inactive.

Sumbul.—The information essential for the answering of your question has not been forwarded.

"*Farr.*"—(1) *Chiococca racemosa.* (2) *Gastridium lendigerum.* (3) *Kœleria cristata.*

T. Morgan.—We have no knowledge of its use in medicine. The root is said to be edible and the leaves afford bowstring hemp. The root of *S. lanuginosa* made into an ointment is used for pains in the limbs in the East Indies.

G. H. J. J.—Leguminosæ: "bastard cabbage bark;" "worm bark." It is anthelmintic, but requires great care in its administration, an overdose producing vomiting, delirium and fever. The powder in doses of 3 or 4 grains purges like jalap.

"*Valerian.*"—(1) *Fucus nodosus.* (2) *Fucus platycarpus.* (3) *Fucus canaliculatus.* (4) *Chœrophyllum temulentum.* (5) *Alchemilla vulgaris.* (6) *Anthyllis vulneraria.*

INTERNATIONAL PHARMACEUTICAL EXHIBITION IN VIENNA.

(Concluded from p. 184.)

Group V.—*Drugs, Chemical Products, Pharmaceutical Preparations and Wares intended for Use in Medicine*—continued.

Section B.—Pharmaceutical Products.

Exhibits from Austro-Hungary, 39; France, 18; Germany, 11; United States, 4; England, 2; Spain, 2; Switzerland, 2; Russia, 2; Turkey, 2; Italy, 1; Norway, 1; Belgium, 1; Holland, 1; Portugal, 1; Brazil, 1: total, 88.

Jurors: Messrs. Hirsch (Frankfurt), Kofler (Dornbirn), Limousin (Paris), Martensen (St. Petersburg), Méhu (Paris), Nedwed (Gratz), Pernwerth (Meran), Scholz (Villach).

This section was perhaps the most important division in the exhibition, since it numbered more than twice as many exhibitors as contributed to any of the other entire groups. One of the most interesting cases in it, that of Gehe and Co., of Dresden, well illustrated the difficulty which attends the carrying out of any attempt at classification, since although it contained a number of extracts, powders, scale preparations, etc., which warranted it being placed among the pharmaceutical products, the most notable features in it were a series of chemical products, which would have given it high rank in Section A, and a collection of drugs which was unsurpassed so far as it went by anything in Section C. The difficulty was, however, probably insuperable, and was productive of no particular inconvenience; the fact is only mentioned here to explain the necessity for sometimes reverting to a class of goods that has been referred to under a previous group or section. All the pharmaceutical preparations shown by Gehe and Co. were included in the upper part of a very fine wall case. It was noticed that several of the thick extracts of the new P.G. were represented by dry extracts, whilst in the dry extract of cannabis indica the firm had adhered to the use of dextrine as ordered in the P.G., 1870, for the dilution of dry narcotic extracts, instead of using liquorice powder, as ordered in the new P.G. As specialties there were ext. farinæ tritici sicc. solub., ext. farinæ leguminosarum, ext. quebracho blanco cort. Penzoldt. sicc., and a yellow porous ext. malti sicc., prepared *in vacuo*. The powders were very fine, the materials for those of ergot and henbane, sabadilla and black mustard seeds having been deprived of oil previously to grinding; but it was most surprising to find that under the name of "pulvis taracanæ" a powder of the *Blatta orientalis* still holds a place in the materia medica. Rhubarb and other drugs cut in small cubes were also shown. There were about fifty different kinds of essential oils in the case, some of them, such as patchouli, peppermint, zedoary, fennel, arnica flowers, etc., being illustrated also by their crystalline constituents. Among the chemical preparations may be mentioned, quinine arsenate and the soluble compound of that alkaloid with carbamide and hydrochloric acid; aspidospermine in brownish-white minute crystals and the citrate of a full brown colour; cocaine as a flesh-coloured powder; aconitine in minute crystals; caffeine salicylate, sulphate and hydrobromate, the last-mentioned in crystals two inches long; colchicine tannate; chinoline tartrate as a somewhat dirty white powder; "pure brucine;" hyoscyamine, amorphous coloured and in crystals; jaborine, the second alkaloid from jaborandi leaves; asaron; cubebin; convolvulin; convallamarin as a fawn coloured powder; β-naphtol, paraldehyde and papayotine. Without having by any means exhausted the list of noteworthy articles in the upper part of Gehe and Co.'s case, it is necessary to pass on to the drugs, which were shown in the lower part of it, but unfortunately in such a position that they could not be seen without stooping uncomfortably. The first object that caught the eye was a splendid exudation of manna *in situ* on a stem of *Fraxinus Ornus* about four feet long. Behind it were a number of Tonquin, Himalaya and Nepaul musk pods, as removed from the animals with skin and adjoining parts of the belly. Some "lacca alba in bacillis" appeared at the first glance almost like hanks of white silk. Masses of "agaricus" (larch agaric), which is reported to be coming into some request again for the manufacture of agaricin, were there of two shapes, one somewhat like a truncated cone, about a foot in height. "Quebracho blanco" was illustrated by the wood, bark, leaves, flowers and fruit of *Aspidosperma Quebracho*, and "quebracho colorado" by the wood of *Loxopterygium Lorentzii*. Of *Carica Papaya* there were the fruit cut open, the flowers preserved in liquid and a mounted leaf, about two feet in diameter. Close by were some fine pieces of the Russian rhubarb that has disappeared from commerce during the last twenty years. A number of different kinds of vanilla were also shown, including two from Mexico, one slender and flattish and the other more nearly approaching the round Bourbon kind; a broad flatter variety from Brazil and a long flat variety from Guyaya. Besides these there were specimens of Japan "brick" tea, described as a "caffeine material," kava kava, coto and other barks. From the foregoing it will be seen that this exhibit was a very instructive one, and well deserved the diploma of honour that was awarded to it.

Another case which presented this mixed character, and was also of considerable merit, was that of Parke, Davis and Co., of Detroit, U.S. It contained samples of most of the numerous vegetable drugs that have been introduced during recent years to the medical profession in the United States as remedies in various disorders, with more or less justification, several of which are now attracting attention in this country and on the Continent. Each drug was accompanied by one or more of the pharmaceutical preparations of it associated with the name of this firm, as well as official preparations of those that have been included in the new United States Pharmacopœia. Some of the exhibits represented different parts of the plants, as for instance the bark from the root and from the branches of *Euonymus atropurpureus*, the former of which yields a brown euonymin and the latter a green compound, which is said to be simply a mixture of the brown euonymin and chlorophyll. In the United States and on the Continent the brown variety is almost exclusively used, but in this country the green appears to be used almost to an equal extent with the brown. Some little time since it was mentioned (*Pharm. Journ.*, [3], xiii., 798) that one of these American drugs named manaca (*Franciscea uniflora*) had been submitted to a preliminary examination by Professor Dragendorff, who had observed indications of the presence of an alkaloid. It is now stated that this has been confirmed by further experiments and that an accompanying fluorescent body proves to be æsculin. The case of J. Schorm, of Vienna, too, would, as before mentioned, have been at least as appropriately placed in the section devoted to chemical products, since in this respect it ranked amongst the best in the exhibition. It contained among other things a series of products illustrating the skilful researches of Dr. Schorm upon the chemistry of the hemlock (*Pharm. Journ.*, [3], xii., 363), including the "pure" coniine, colourless and boiling at 168° C.; coniine hydrobromate in very fine crystals; coniine hydriodate in crystals, and other salts, as well as crystalline masses of conhydrine, which Dr. Schorm, in the paper referred to, states that he obtains in the residuary fraction, boiling above 169° C., from the purification of coniine.

Turning now to the exhibits in this section more strictly in keeping with its official description mention may be made first of one from the pharmacy of the General Hospital, Vienna, in connection with which, as already mentioned (before, p. 141), the manufacture of medicinal preparations for the supply of other hospitals is carried on under the superintendence of the Vienna Haupt-Gremium. Amongst the articles here shown were "caustic arrows," prepared from zinc chloride, for use in carcinoma; pellets of caustic potash, for bullet wounds; caustic pencils of alum, and of copper and zinc sulphates; various gelatine preparations, for external use in skin diseases (see before, p. 63), containing respectively 1 per cent. of carbolic acid, 10 per cent. of chrysarobin, 50 per cent. of iodoform, 5 per cent. of pyrogallic acid, 10 per cent. of salicylic acid and 10 per cent. of zinc oxide; a 10 per cent. carbolic gauze; a 50 per cent. iodoform gauze and a plaster of the same strength, as well as other external appliances suggestive of the extent to which iodoform is now used as a dressing. Notwithstanding that there was a special section for dressings, there were several excellent displays of plasters here, among which may be mentioned those of Seabury and Johnson, of New York; R. Jacobi, of Elberfeld; and E. Dieterich, of Helfenberg. Some very good elastic bougies, uniform in appearance, said to be made from a "basis of cacao butter," as well as some very good looking medicated gelatine squares, for hypodermic use, were shown by C. Haubner, of Vienna. Close by, A. Sauter, of Geneva, exhibited suppositories of cacao butter, made hollow for the reception of any desired medicament. These suppositories consist of two parts, the larger being the receptacle for the medicinal substance, whilst the smaller acts as a stopper. It is claimed that when placed in the rectum these suppositories become liquefied in from five to ten minutes, and that in the meanwhile a complete intermixture of the medicine with the fat is effected. As they are moulded by pressure, instead of the fat being melted, they present a very homogeneous appearance. Gelatine capsules; compressed tablets, in which the drug to be administered is sometimes alone and sometimes mixed with cane sugar, sugar of milk, or chocolate; medicated "sugar-plums;" coated pills and various other articles of pharmaceutical confectionery, were too numerous to allude to in detail, and of a nature impossible to pronounce upon as to quality from the very limited assistance afforded by outward appearance. Among these, the nitro-glycerine tablets of W. Martindale, of London, excited considerable curiosity. The one other English firm that exhibited in this section was Fletcher, Fletcher and Co., who showed their liquor ferri iodidi and other concentrated liquors. Silver medal diplomas were awarded to both these exhibitors. France was well represented in this section, although the exhibits of the Pharmacie Centrale (E. Genevoix and Co.) and the Société Française (Adrian and Co.) came far short of the splendid displays made by those firms in Paris in 1878. Numerous preparations of cinchona and its alkaloids,—conserves, tablets, pills, syrups, wines, etc.,—bore ample evidence of the wide usefulness of this article of the materia medica. It is, indeed, impossible to mention separately all that was noteworthy in this section, but an exception must be made in favour of an exhibit of chemical and pharmaceutical preparations and Brazilian drugs, from Dr. G. Peckolt, of Rio Janeiro, who has done so much valuable work in clearing up the history of South American drugs.

Among the preparations for medicinal purposes that would appear somewhat unfamiliar to the English pharmacist were some displays of fruit juices, that of raspberry preponderating, from the fact that this fruit grows freely on the Styrian slopes and many parts of the Carpathian mountains. Another indigenous class of preparations were those obtained from coniferous plants, among which may be mentioned the oil distilled from the young shoots of the dwarf pine (*Pinus Pumilio*), which has a considerable reputation as a medicine among the Hungarians, and an extract from the same plant, which is made by boiling the shoots with water, and is used as an addition to baths; and similar products from the Norway spruce fir (*Abies excelsa*). Another preparation which might attract attention by its apparently undue frequency, was cherry-laurel water; but it is official in the Austrian Pharmacopœia, and is the only form for the administration of hydrocyanic acid given in the German Pharmacopœia. A fine collection of cold-pressed oils was exhibited by H. Falkner, of Vienna, and as the tests mentioned are evidently the result of practical experience, it may be useful to quote them briefly. Almond oil (sweet): clear straw-yellow; sp. gr, at 20° C. 0·917 - 0·920; solidifies at - 20° C. to a white mass; shaken with nitric acid forms a whitish mixture, soon becoming reddish-yellow; mixture of 20 drops with 3 drops of sulphuric acid causes a yellow turbidity, afterwards becoming greenish-yellow and then brownish olive-green, the oil at the same time thickening; with lead subacetate it shows a greyish-white turbidity, but a yellowish turbidity when other oils are present; dissolves in 25 parts of cold, and 6 parts of hot alcohol, very readily in ether. Castor oil: sp. gr. 0·95 - 0·97; solidifies at - 18° C., but throws down a granular deposit of the glyceride of ricinolic acid at - 12° C.; completely soluble in absolute alcohol. Linseed oil: sp. gr. 0·93 - 0·94; with nitric acid, sp. gr. 1·3, a sulphur-yellow; 10 drops with 3 drops of sulphuric acid a red-brown resinous mass. Poppy oil: sp. gr. 0·92 - 0·925; solidifies at - 20° C.; gives with ammonia a white, and with potash solution a yellowish-white emulsion. Hempseed oil: sp. gr. 0·925 - 0·927; solidifies at - 16° C.; when fresh coloured grass-green by concentrated hydrochloric acid, and yellow-green when old. Nut oil (walnut): sp. gr. 0·925; gives a yellowish-white liniment with a solution of potash or ammonia. Mustard oil: sp. gr. 0·914; solidifies at 18° C.; coloured a dark grey-green by zinc chloride. J. F. Schutz, of Breitensee, near Vienna, exhibited pure chlorophyll, and preparations of it, intended for use in colouring fatty oils, soaps, liqueurs, tinctures, etc. Another collection worth notice was that of V. Zanni, of Constantinople, who exhibited Chian turpentine, gum mastic, and sem. anisi, all from the island of Scio, as well as salep and scammony resin.

Before leaving this section mention must be made of the important exhibit of medical appliances from the medicament branch of the Austrian war department. It consisted of a section of a field pharmacy, in three compartments; two medicine chests of different sizes; a bandage and medicine knapsack intended for an infantry or jager battalion and a similar provision for a cavalry division. The display was by no means out of place in such an exhibition, for the fact that many of the visitors were familiar with military service vested it with considerable interest. It may be added that in connection with this exhibit some very interesting information has been published concerning the organization of the military pharmaceutical service in the Austro-Hungarian empire, which will be found referred to more fully on another page.

Section C.—Drugs.

Exhibits from Austro-Hungary, 14; Germany, 1: total, 15.

Jurors: Messrs. Reichardt (Vienna), and Winkler (Innspruck).

In this section were two very valuable exhibits of drugs from collections belonging to public institutions. One of these was from the museum of the General Austrian Pharmaceutical Association, and included a large number of specimens of cinchona bark, many of which had been presented to the Society by Mr. J. E. Howard and classified by Dr. A. Vogl; also numerous specimens of opium, rhubarb, jalap, vanilla and other drugs. Another interesting feature in it was a large collection of vegetable seeds numbering 2200 different kinds. The other contribution was from the Oriental Museum, in Vienna, and included large collections of drugs from Japan, India and China, numbering some three or four hundred specimens. As it would be inconsistent with the purpose of this report to introduce a mere catalogue of names or to extend it to the length that would be required to notice, however briefly, all that was interesting in these collections, it must suffice to say here that the specimens were as a rule in admirable condition and conveniently shown, whilst it must be evident that they contained very much to attract the attention of the enthusiastic pharmacologist. Amongst the private exhibitors in this section, F. Wilhelm, of Vienna, was undoubtedly entitled to the diploma of honour awarded to him for the admirable manner in which the idea of exhibiting drugs in their original packages was carried out. In this way sarsaparilla was shown in bundles bound at the end with skin, hepatic aloes in monkey's skin, Barbadoes aloes in a gourd, balsam of peru in square iron canisters, maté in a skin with the hair still on, original canisters of star-anise oil, etc. A fine collection of the more important drugs was shown by L. Duvernoy, of Stuttgart, including a number of samples of Palembang, Sumatra and Siam benzoin; ergot, probably Russian; Hudson's Bay castoreum, the only kind now official in the P.G.; picked gum arabic and a fine white powder of gum arabic apparently precipitated by alcohol; also, wild and cultivated varieties of *Pyrethrum* flowers for insect powders. Another noticeable display, shown by F. Bednar, of Voecklabruck, Upper Austria, consisted of a number of specimens of beeswax from different countries, both in the raw condition and bleached.

Section D.—Mineral Waters, Wines, Articles of Food and Spirit.

Exhibits from Austro-Hungary, 31; Germany, 4; Russia, 3; France, 2; Switzerland, 2; England, 1; Sweden, 1; Norway, 1; Italy, 1; Roumania, 1: total, 47.

Jurors: Messrs. Fredrich (Vienna), Gruener (Hernals), Hoffmann (Klosterneuburg), and Schacht (Berlin).

Very little can be said concerning the nature of the exhibits in this section beyond what is disclosed in the title. As is usual in continental exhibitions, natural mineral waters were well represented, including, of course, in this case, the celebrated Austrian Carlsbad water, the Bohemian Pullna, and the Franz Josef and several others from springs in Hungary. There were also the more or less pure saline deposits and leys from mineral springs, which are largely in demand for baths. Cognac brandy, and Greek, Italian, Spanish, Portuguese and French wines for medicinal purposes, as well as medicated wines, were shown in a quantity indicating that the alcoholic medium for administering medicines is not losing favour in Eastern Europe. One exhibitor, G. A. Kamner, of Vienna, showed a medicated wine described as having been prepared by allowing the grape juice to ferment in contact with iron and cinchona bark, the product, it is claimed, remaining clear and unaltered indefinitely. Then there were "caravan" tea from Russia, cocoa, chocolate, coffee and coffee substitutes and mixtures. Another class of goods in this section, which may be looked upon as the outcome of recent physiological investigation, assisted, perhaps, by fashion in prescribing, consisted of numerous peptones, pepsins, diastases, malt extracts, and similar preparations, together with meat powders, flesh solutions, extract of meat (well represented by the Fray-Bentos Company), and infants' foods of all kinds. A powder of the yelk of eggs and another of the white of eggs, were shown by A. Haberkorn, of Moscow, together with other preparations of egg albumen. Lastly, there were specimens of koumiss from Russia and from Jaroslau, Galicia, where the first koumiss "curort" in Austria has recently been established. According to a statement made in connection with this establishment, the composition of the natural koumiss may be represented as follows:—

	In 1000 parts.	
	From	To
Casein	12·32	18·23
Albumin	3·14	4·10
Lactoprotein	5·71	6·08
Sugar in fresh koumiss	—	57·28
Sugar in koumiss 15 days old.	—	6·41
Alcohol in fresh koumiss	—	12·31
Alcohol in koumiss 15 days old	—	20·31
Carbonic acid, dissolved	—	3·59
Carbonic acid, free	—	4·86

Together with sodium, potassium, magnesium, calcium and iron salts, and a relatively large quantity of fat.

Section E.—Dressings, Surgical Appliances, Soaps and Perfumery.

Exhibits from Austro-Hungary, 7; Germany, 3; Switzerland, 1: total 11.

Jurors: Messrs. Fridrich (Vienna) and Mosetig (Vienna).

A considerable proportion of the articles included in this section were of the same nature as some that have already been alluded to, consisting of various kinds of textile material saturated with antiseptics and other medicaments, and need not be referred to further. Mention may be made, however, of "wood wool," the disintegrated fibre of fine-grained non-resinous wood (*Pharm. Journ.*, [3], xiii., 995), exhibited by Hartmann and Kiesling, of Hohenelbe, Bohemia, which is said to be coming in use as a surgical dressing, one advantage claimed for it being its great capacity for absorption. There were also numerous medical and surgical appliances, among which was an ingenious apparatus for applying heat to the body, consisting of spiral coils of tinned lead piping, bent in different shapes to fit the surface of different parts, through which a current of water at any desired temperature can be maintained by a siphon arrangement.

Group VI.—*Contributions to the History of Pharmacy.*

Exhibits from Austro-Hungary, 35; Germany, 1; Spain, 1; Switzerland, 2; Russia, 1: total, 40.

Jurors: Messrs. Greenish (London), Janota (Falkenau), and Peters (Nuremberg).

No attempt can be made here to deal in detail with the exhibits in this group, which was devoted to articles of purely antiquarian interest. But it must be said that probably never was such a collection brought together before. It contained treasures loaned from several public institutions in Austria, the German National Museum in old-world Nuremberg, and various private collections. One portion of it, consisting of a number of most interesting glass, majolica, and other earthenware vessels, bronze mortars and other metal utensils, many dating from the sixteenth century, were ingeniously utilized to fit up a model pharmacy of the middle ages, which was examined with interest and curiosity by nearly every visitor to the exhibition. Then there were books bearing more or less closely upon pharmaceutical subjects, dating from the earliest days of printing, as well as decrees, privileges, concessions, and indentures of all kinds, many of them of great age, some of considerable beauty, and others bearing the signatures of mighty potentates. Of course, as a rule, only the title-pages of the books could be seen, whilst the business of the documents was only partially revealed. But from one of these, a deed of apprenticeship, dated 1663, some consecutive lines were culled as indicating the requirements from intending pharmacists two centuries ago, and these may be quoted, as a concluding note, for the benefit of those who lament the great stringency of the regulations in the present day. They run thus:—"Ego Henricus Berchfeld, Pharmacopoeus, Reipublicus Ulmensis Iratus, Omnibus et singulis cujuscumque Conditionis tandem fuerint, praesertim Artis Pharmaceuticae addicis, notum facio, et hac mea manu propria attestor, Praesentem Humanissimum Juvenem Alexandrum Jacobum Ditel, postquam fundamenta latinae linguae jecerit, et deinde animum suum ad studium pharmaceuticum applicarit per quatuor annos, et ultra mea officina inservisse, et annos suae disciplinae absolvisse," etc.

STUDIES IN THE CHEMISTRY OF TARTARIC ACID.

BY THE LATE B. J. GROSJEAN.

(*Concluded from page* 188.)

II.—Destruction of Citrates and Tartrates by Hydrogen Peroxide.

The following experiment, made in 1880, will serve as an example of the results obtained:—

Five c.c. of a saturated solution of tripotassic citrate were treated with 20 c.c. of dilute sulphuric acid and 40 c.c. of a solution of hydrogen peroxide (1 vol. = 10 vols. oxygen). The whole was then boiled in a glycerine bath for two hours. At the end of this time the solution had become neutral. The acid destroyed was equivalent to about 1 gram of citric acid. When the action was pushed further by new additions of hydrogen peroxide the solution became alkaline. In a blank experiment, omitting the hydrogen peroxide, no loss of acidity was observed. On boiling a solution of potassium bitartrate, or an acidified solution of Rochelle salt, with hydrogen peroxide, the solutions became alkaline. The hydrogen peroxide has apparently no action in the cold, at least not in a short time.

III.—Destruction of Neutral Tartrates when their Solutions are heated with an Iron Salt.

The following experiments were made in 1880:—

1. A mixture containing 2 grams tartaric acid and 0·3 gram of ferrous sulphate, in 200 c.c. of water, was neutralized with potash, and then concentrated to 50 c.c. The tartaric acid was precipitated by the addition of 2·5 grams of citric acid with 5 grams of potassium chloride, and continuous stirring for ten minutes. The potassium bitartrate obtained was equal to only 91·0 per cent. of the tartaric acid taken.

2. The first-named experiment was repeated, but the neutralization with potash was omitted. The concentrated solution was precipitated with 2 c.c. of a saturated solution of potassium citrate, 0·5 gram of citric acid and 5 grams of potassium chloride being also added. The tartaric acid found was 99·6 per cent. of that taken.

Many similar experiments appeared to show that little, if any, loss of tartaric acid occurred during the evaporation of solutions containing iron when these solutions contained free tartaric acid and not tartrates. The subject, however, requires further experiments. The power of ferric salts to decompose tartaric and other organic acids under the influence of light has been noticed by many chemists.

IV.—Determination of Free Sulphuric Acid in Tartaric Acid Liquors.

The experiments detailed in this section were made in the years 1880 and 1881. They relate both to the qualitative and quantitative determination of sulphuric acid in tartaric liquors.

In a tartaric acid factory it is necessary to have some simple means of ascertaining when an excess of sulphuric acid has been added for the decomposition of calcium tartrate. The test employed by the workmen consists in adding to a portion of the liquor a few drops of solution of calcium chloride. If in a few minutes a precipitate of gypsum appears, it is known that an excess of sulphuric acid is present. This test is certainly ingenious. Barium chloride would here be quite unsuitable, as the liquor is saturated with sulphate of calcium. Mr. Grosjean made a study of this factory test. He found that under suitable conditions it was capable of detecting a very small quantity of sulphuric acid, and that by its use under known conditions a rough estimate may often be formed of the quantity of acid present.

A selection of the experiments made will be found in the following table. All experiments were made with 50 c.c. of a 10 per cent. solution of tartaric acid, to which known quantities of sulphuric acid had been added. The tartaric solution was saturated with gypsum at 35°, to imitate the conditions usual in the factory during the decomposition of calcium tartrate; the solution was cooled to

15° before treatment; the calcium chloride was employed as a saturated solution. The amount of free sulphuric acid in each solution is expressed in terms of brown oil of vitriol, and also in its equivalent of sulphuric anhydride. The former expression is employed as the one most suitable to the manufacturer, brown oil of vitriol (sp. gr. 1713) being the acid he employs.

Table III.—Results of adding Saturated Calcium Chloride Solution to 50 c.c. of a 10 per cent. Solution of Tartaric Acid containing known Quantities of Sulphuric Acid.

Sulphuric acid present. Per cent.		Calcium chloride solution taken.	Time required to produce turbidity.
Reckoned as B. O. V.	Reckoned as sulphuric anhydride.		
0·5	0·315	15 drops	Not in 2 hours
0·8	0·504	15 drops	30 minutes
1·2	0·756	15 drops	15 minutes
1·2	—	30 drops	8 minutes
1·2	—	45 drops	Turbid at once
0·8	0·504	45 drops	8 minutes
0·8	—	60 drops	5 minutes
0·8	—	90 drops	4 minutes
0·8	—	120 drops	3 minutes
0·8	—	10 c.c.	2 minutes
0·8	—	24 c.c.	Turbid at once
0·4	0·252	34 c.c.	Turbid at once
0·5	0·315	7 c.c.	5 minutes
0·2	0·126	18 c.c.*	5 minutes
0·1	0·063	25 c.c.	5 minutes

These results show that when the proportion of sulphuric acid present is very small, very large amounts of calcium chloride are required to give rise to a precipitate of gypsum. Both the delicacy and rapidity of the reaction are increased in proportion to the amount of calcium chloride employed. By constructing a table somewhat similar to the above, it becomes possible, when testing new factory liquors, containing nearly the same proportion of tartaric acid and saturated with gypsum, to ascertain approximately the percentage of free sulphuric acid present by observing the proportion of calcium chloride required to produce a turbidity in five minutes.

Mr. Grosjean found that a saturated solution of gypsum, containing neither sulphuric nor tartaric acid, yielded a precipitate on the addition of a considerable quantity of calcium chloride. It is clear, however, that gypsum alone will not produce a precipitate in the presence of much tartaric acid. A few experiments were made on the effect of varying proportions of tartaric acid. In solutions containing 1 per cent. B.O.V. an increase in the tartaric acid from 5 to 10 per cent. appears to retard the precipitation by calcium chloride.

The quantitative method already suggested for the determination of sulphuric acid in tartaric liquors (*Jour. Chem. Soc.*, 1875, 981) consisted in first pouring the liquor into alcohol to precipitate sulphates, and then precipitating the sulphuric acid in the alcoholic solution by the addition of calcium chloride. As the calcium sulphate thus obtained is apt to contain calcium tartrate, it was recommended that this precipitate should finally be dissolved in hydrochloric acid, and the sulphuric acid thrown down with barium chloride. Mr. Grosjean found, by a test experiment with a known quantity of sulphuric acid, that the whole of the sulphuric acid is not finally precipitated by barium chloride when the calcium precipitate is much contaminated by tartrate. He found it more accurate to ignite the mixed sulphate and tartrate of calcium, treat the ash with strong nitric acid to oxidize any sulphide, and then, after driving off the excess of acid by heat, to add alcohol, and collect and weigh the calcium sulphate.

* This quantity is approximate only.

V.—Determination of Tartaric Acid by Precipitation as Potassium Bitartrate.

The method formerly proposed for determining the tartaric acid in the tartaric acid liquors of a factory (*Jour. Chem. Soc.*, 1875, 976) consists in precipitating the tartaric acid with an excess of tripotassic citrate, collecting and washing the potassium bitartrate produced, and determining its amount by titration with standard alkali. Mr. Grosjean's observation that the precipitation of the bitartrate was complete after ten minutes' continuous stirring at 10° to 15° has greatly facilitated the use of this method. The washing of the precipitate was at first performed with alcohol, or with cold saturated solution of potassium bitartrate; but for these washing fluids a 5 per cent. solution of potassium chloride, saturated with potassium bitartrate, was soon substituted. Mr. Grosjean found (*Trans. Chem. Soc.*, 1879, 348) that this solution contained at 12° but one part of potassium bitartrate in 3·213 of solution.

A cognate method to the above was proposed at the same time (*Jour. Chem. Soc.*, 1875, 972) for the determination of tartaric acid in lees. In this case the whole of the tartaric acid is brought into the condition of neutral potassium tartrate by acting on the lees with potassium oxalate and neutralization with potash, and the tartaric acid is then thrown down as potassium bitartrate by the addition of citric acid.

Both these methods Mr. Grosjean patiently and thoroughly examined. His results relative to the latter form of the method have been already in part communicated to the Chemical Society (*Trans.*, 1879, 341). His experiments on the application of the method to the analysis of tartaric acid liquors have now to be described. The investigation was chiefly conducted during the years 1880 and 1881.

The conclusion finally arrived at by Mr. Grosjean was that the method was liable to two errors in opposite directions. (1) An error of excess, due to the precipitation of an acid citrate of potassium with the potassium bitartrate; (2) an error of deficiency, due to the solubility of potassium bitartrate in solutions of citric acid and citrate of potassium. He believed that perfectly correct results were only obtained when these errors balanced each other.

Mr. A. H. Allen had early called attention (*Chem. News*, 1876, 31, 278) to the precipitation of an acid potassium citrate from a solution containing citric acid and potassium acetate in proof spirit; but as no alcohol was present in our solutions, and the precipitate produced in the reaction quoted is freely soluble in the washing fluid (5 per cent. potassium chloride saturated with bitartrate) we employed, neither Mr. Grosjean nor I at first considered that the presence of an acid citrate in the washed bitartrate was at all probable. The following facts subsequently led Mr. Grosjean to a different conclusion:—

1. In trials with known quantities of tartaric acid, the acidity of the bitartrate obtained would be deficient unless a rather considerable excess of citric acid was present at the time of its precipitation (*Trans. Chem. Soc.*, 1879, 348). When the excess of citric acid was too small, and the result deficient, no further amount of bitartrate was precipitated on adding citric acid to the filtrate.

2. In test experiments with known quantities of tartaric acid the potassium bitartrate precipitated by certain proportions of potassium citrate would have an acidity equivalent to more than the tartaric acid taken. When tartaric acid was used alone the excess would seldom exceed 1 per cent., but when much free sulphuric acid was originally present the excess might reach 3 to 4 per cent., unless extreme pains were taken in washing the precipitate.

3. Great difficulty was frequently experienced in washing the bitartrate precipitate so that the acidity of the drain water should be no greater than the acidity of

the washing fluid. The first stages of the washing would be easily accomplished, but when the washing seemed nearly completed the acidity of the drain water would often obstinately remain a little above that of the washing fluid, notwithstanding a very large amount of washing. The most effective mode of washing was to stir the precipitate with a washing fluid in a beaker, and repeat this treatment several times before transferring the precipitate to the filter.

4. Precipitates of bitartrate redissolved in a small volume of hot water and thrown down again by cooling, with the addition of potassium chloride, would frequently lose 2 per cent. or more of their acidity. Bitartrate thus reprecipitated always washed with great ease.

5. Citric acid could be detected in the washed precipitates. The mother liquid obtained in reprecipitating the bitartrate (see preceding paragraph) was neutralized with soda and treated with calcium chloride. After long standing in the cold, to separate a little calcium tartrate, the clear solution was boiled and a small quantity of calcium citrate obtained.* A little citrate was equally detected in the washed bitartrate obtained in the analysis of lees by the oxalate method.

The above facts all point to an error of excess, due to the precipitation of a small quantity of an acid citrate. The liability to an opposite error from the solubility of bitartrate in citric acid, and especially in citrate of potassium, is evident from the results already published (*Journ. Chem. Soc.*, 1875, 946) relating to the solubility of potassium bitartrate in various acids and salts. Here, again, the source of error will be greater when the original solution contains sulphuric acid, the quantity of citric acid produced in the reaction being thus increased, and also the difficulty of avoiding an undue excess of potassium citrate.

In Tables IV. and V. will be found a few series of test experiments, in which the same tartaric solution was treated with varying proportions of potassium citrate. The tartaric solutions taken purposely contained (save in Series IV.) a very large proportion of sulphuric acid thus resembling the worst liquors of a factory. In all these experiments the amount of tartaric acid found (shown by the acidity of the washed precipitate) rises with increasing additions of potassium citrate till a maximum yield is obtained. Beyond this point each further addition of potassium citrate occasions a diminution in the tartaric acid obtained.

				23	95·1

* Mr. Grosjean found that a good method of testing a calcium salt for tartaric acid was to dissolve in a small quantity of acetic acid, and add a considerable amount of potassium chloride. Potassium bitartrate is then precipitated if tartaric acid is present.

In each of the experiments in Series I. and II. the quantities of tartaric and sulphuric acid named in the table with 5 grams of potassium chloride, were dissolved in such a volume of water that the addition of the potassium citrate mentioned in the table would bring the whole to 50 c.c. The ingredients being mixed, the whole was stirred for ten minutes, the temperature being kept between 10° and 15°. The precipitated bitartrate was naturally mixed with much potassium sulphate. It was washed with a 5 per cent. solution of potassium chloride, saturated with bitartrate. The commencement of the washing was by decantation, 25 c.c. of the washing fluid being successively employed. The washing was continued on a vacuum filter, and was maintained till the acidity of the drain-water was permanently only very slightly above the acidity of the washing fluid: to accomplish this half a litre of the washing fluid was generally required.

The experiments in Series III. were made at an earlier date than the preceding. The ingredients taken represent a very bad old liquor. The volume of the solution was in all cases 45 c.c.: to this the potassium citrate named in the table was added, with 5 grams of potassium chloride, and the whole stirred for ten minutes at 15°. The washing was conducted on a vacuum filter, 200 c.c. of washing fluid being employed.

In Series IV. and V., Table V., the precipitation and washing were conducted exactly as in I. and II. The precipitates were then redissolved in 50 c.c. of hot water, 5 grams of potassium chloride added, and the whole quickly cooled with stirring to 15°, at which temperature stirring was continued for ten minutes. From this purified precipitate all adhering acidity was readily removed by the ordinary washing fluid. The maximum product obtained in these purified precipitates is seen to be 97·5 to 97·9 per cent. of the tartaric acid taken. The unavoidable loss attending reprecipitation from 50 c.c. of a 10 per cent. potassium chloride solution would, however, be nearly 0·5 per cent., and this may fairly be added to the above figures.

2·5	97·9	10	96·2
3·0	97·4	11	97·5
—	—	12	94·1

The final conclusion arrived at by Mr. Grosjean was that in all accurate determinations of tartaric acid in factory liquors it was necessary to make a preliminary series of experiments with graduated quantities of potassium citrate, with the view of discovering the proportion of citrate which gave the precipitate of maximum acidity.

This series of experiments need not take long, as stirring for ten minutes suffices to precipitate the bitartrate, and for the present purpose a moderate amount of washing would suffice. The right proportion of citrate being ascertained, a final determination would be made with this quantity, the precipitate in this last experiment being very thoroughly washed after the method employed in the experiments of Series I. and II. The acidity of the bitartrate thus obtained would correctly show the tartaric acid present if the original liquor contained but little sulphuric acid, or would be about 1 per cent. in excess of the truth if much sulphuric acid was present.*

In Mr. Grosjean's already published paper (*Trans. Chem. Soc.*, 1879, 352), he states that he is in the habit of removing excess of sulphuric acid from a tartaric liquor by neutralization with potash, and allowing the potassium sulphate to crystallize out before proceeding to the precipitation of the tartaric acid, which is then effected by citric acid. This method was afterwards abandoned. In impure liquors the potash produced a gelatinous precipitate difficult to wash. Experience also showed that a neutralized tartaric liquor containing iron suffered loss of tartaric acid during concentration. (See Section III. of this paper.) The precipitation of the impure tartaric liquor with excess of whiting, and the decomposition of the precipitate with potassium oxalate, recommended by him in the same paper (*ibid.*, 352), were also given up, test experiments showing low results, the cause of which was, however, not fully traced out. In the case of very bad old liquors it is possible that potassium alum may be precipitated on adding the potassium citrate. This precipitation of alum is due, Mr. Grosjean showed, to its small solubility in a solution containing potassium sulphate, a salt which is formed in abundance on adding potassium citrate to a liquor rich in sulphuric acid. When alum has been precipitated along with the potassium bitartrate the result of the analysis will show a deficiency, if the washing is conducted with the usual 5 per cent. solution of potassium chloride saturated with bitartrate. The alum readily dissolves in this fluid, and forms a solution in which potassium bitartrate is readily soluble. Mr. Grosjean confirms the former observation (*Jour. Chem. Soc.*, 1875, 979) that the presence of phosphoric acid in sufficient quantity effectually prevents the precipitation of alum. When, however, both phosphoric acid and alumina are present, it is necessary to collect the precipitated bitartrate immediately after the ten minutes' stirring, as a gelatinous precipitate of aluminium phosphate is apt eventually to occur.

VI.—Detection of Tartaric Acid in Citric Acid.

Cailletet's method (*Jour. Chem. Soc.*, 1879, abstracts 674) answers well. Three grams of citric acid, with 0·03 gram of tartaric acid (1 per cent.), were dissolved in 65 c.c. of water, 0·2 gram of sulphuric acid and 10 c.c. of a saturate solution of potassium bichromate added. In twenty minutes the solution was quite dark in colour, while a comparative solution containing citric acid only remained for several hours light coloured. Next day the purely citric solution was dark, but still transparent, while that containing 1 per cent. of tartaric acid had become opaque.

VII.—Determination of Organic Acids from the Neutralizing Capacity of the Ash of their Salts.

This simple mode of determination is frequently adopted in the analysis of tartrates and citrates. Mr. Grosjean was convinced that potassium and sodium salts must always be ignited at a low temperature, that of an ordinary spirit-lamp flame, if loss of base is to be avoided. With calcium salts no such precaution was needed.

VIII.—Standardizing of Alkali used for Titration.

The best material for standardizing alkali is pure bitartrate of potassium. It is easily prepared, may be dried without alteration at 100°, is not hygroscopic, and being of low acidity, a large weight may be taken for a determination. Delicate litmus paper answers best to ascertain the point of neutralization. If the bitartrate is prepared from commercial cream of tartar it must be first recrystallized from a hydrochloric solution to remove calcium tartrate, and again crystallized from water; but the simplest method is to start with pure tartaric acid and potassium carbonate.

* It is clearly very desirable to have some means of knowing, at least approximately, when a sufficient amount of potassium citrate has been employed. When the amount of tartaric acid present is partly known, it is useful to remember that 1 gram of tartaric acid may be precipitated by about 1 c.c. of a saturated solution of potassium citrate. When much free sulphuric acid is present, potassium sulphate is first precipitated as a fine powder. The commencement of the precipitation of bitartrate may generally be recognized by the formation of streaks on the side of the vessel when rubbed by the stirrer. When this point is reached a measured quantity of potassium citrate solution proper for the tartaric acid presumed to be present can then be added. It is obvious, also, that the citrate may be added till a drop of the clear liquid removed to a watch-glass gives no more precipitate when treated with a very small quantity of fresh citrate, and the mixture rubbed with a glass rod.—R. W.

NOTES OF CARBOLIC ACID.*

The United States Pharmacopœia says "100 parts of the crystals are liquefied by the addition of about 5 parts of water; this liquid is rendered turbid by the further addition of water until 2000 parts have been added, when a stable and clear solution is formed." This is equivalent to saying that the crystallized acid will dissolve only about 5 per cent. of water, and that water will dissolve only about 5 per cent. of the acid, and that all the proportions between these points are turbid mechanical mixtures or emulsions. This description is in more or less general accord with the older and some recent authorities, but it applies only to mixtures of phenols, and these mixtures have of late years been separated, and have been found to differ widely in many respects. That is, the phenols are now found to be as different from each other as are the alcohols, and the phenol which is written with a capital P, namely, this crystallized carbolic acid, is as different from other phenols of the class as is common ethylic alcohol from others of the class of alcohols. Some modern authorities are more accurate in their descriptions of carbolic acid, and it is unfortunate that the Pharmacopœia did not follow these. For example, the Pharmacopœia says that crystallized carbolic acid dissolves about 5 per cent. of water, while Allen—'Commercial Organic Analysis,' Phila., 1879, p. 303—states that it dissolves about 27 per cent.

Repeated trials with a commercial carbolic acid free from creasote odour, which congealed at 38° C. = 100·4° F., gave results as follows:—

To 100 c.c. of the melted crystals warm distilled water was added, ten c.c. at a time, the solution being kept at about 54° C. = 129·2° F., until 60 c.c. of water was dissolved, making a perfectly transparent solution as long as the temperature was maintained at about that point. But on cooling a few degrees the whole became an opaque white emulsion. This, on standing forty-eight hours, separated into a transparent lower portion measuring 135 c.c. and an upper stratum of 25 c.c. The upper part of this stratum, measuring about 15 c.c., was a perfectly transparent watery solution, saturated of course; the intervening portion of 10 c.c. was a white emulsion containing a very little very finely divided acid, suspended in minute cells in the watery solution. Thus this acid had dissolved not less than 35 c.c. of water, and held it in perfect solution at 20° C. = 68° F., while by the Pharmacopœia it should only have dissolved about 5 c.c. The solution contained nearly 26 per cent. of water and was saturated. Of the same acid, melted, 10 c.c. were well shaken with 90 c.c. warm water, and nearly, but not quite, all dissolved. On standing forty-eight hours the lower undissolved stratum measured 4 c.c., 6 c.c. having been held in solution in 96 c.c. of the solution, or about 6 per cent., 5 per cent. being the solubility given by the United States Pharmacopœia.

When a saturated solution of the crystals containing 6 per cent. was carefully poured upon an equal volume of purified chloroform in a graduated cylinder, and the mixture was carefully moved to and fro in the cylinder with-

* From Dr. Squibb's *Ephemeris*.

out active agitation and without making a white emulsion, as by very active agitation, the volume of the chloroform layer was increased very nearly 5 per cent. That is to say, chloroform is not as easily dissolved by water as carbolic acid is by chloroform, and therefore by care most of the acid can be dissolved out of the water without permitting the chloroform to take up much of the water, or the water much of the chloroform. All ordinary chloroform contains a small proportion of alcohol, and this is washed out by brisk agitation with water, and increases the solubility of chloroform in the water. Under these conditions the test must be inaccurate unless the chloroform dissolves the same proportion of water that the water does of chloroform, and this is not the case at the point of saturation at ordinary temperatures. Besides, when any solution of carbolic acid has been shaken with chloroform, the watery stratum smells and tastes strongly of both chloroform and carbolic acid.

When 50 c.c. of crystals saturated with water, and containing 27·18 per cent. of water, were shaken with 50 c.c. of chloroform, either with or without active agitation, the upper watery layer measured 10 c.c., indicating 20 per cent. of water when the solution contained 27·18 per cent. of water in addition to the 1 or 2 per cent. of water that the crystals originally contained.

Thus the chlorform test rigidly re-applied to a saturated solution of carbolic acid in water did not indicate the acid known to be present by 16 per cent., for the water actually contained 6 per cent., while the test indicated only 5 per cent.

Applied to carbolic acid, congealing at 38° C., saturated with water and known to contain 27·18 per cent. of water, the test indicated only 20 per cent., or say 73·5 per cent. of the water actually present. Hence the general statement that the chloroform test for solutions is practically valueless is sustained.

Some very good authorities state that benzene will wash all the carbolic acid out of its solutions, and leave the water to be measured. But such is not the case with any benzene that is commonly accessible.

The quantity of carbolic acid dissolved in any given solution may be roughly got at by adding 6 c.c. of melted crystals to 94 c.c. of the solution in a 100 c.c. graduated cylinder, warming the mixture, shaking vigorously, and then allowing it to separate. When cold the solution is now fully saturated at the temperature of the observation, and the undissolved excess may be read off. If 2 c.c. of the 6 shall have been dissolved, then the solution already contained about 4 per cent., since a saturated solution at ordinary temperatures contains about 6 per cent.

A very nice solution has been largely employed for many years past, and its use is constantly increasing. This is generally called "Disinfectant Solution of Coal-tar Creasote, or Solution of Impure Carbolic Acid," and it should contain about 2 per cent. of the mixed phenols which constitute the "Crude Carbolic Acid," U.S.P. It is very quickly and easily made, simply by agitating well 2 parts of the crude carbolic acid, U.S.P., with 98 parts of water, and filtering through a wet paper filter.

This is a clean and colourless solution, entirely volatile, and it does not injure clothing, carpets, bedding, or anything of the kind, and therefore it may be sprinkled freely upon anything, however nice.

This solution, I believe, is the form most convenient and effective for the treatment of all superficial or cutaneous pain as an anæsthetic. If the fingers be held immersed in this solution for ten minutes, in half that time the cuticle will begin to turn white, the skin to shrivel like a washerwoman's hands, and a slight numbness will be felt. These all increase, and at the end of ten minutes are marked, and the increased numbness is accompanied by a pricking sensation suggestive of the smarting pain which longer immersion produces, and of which this is the beginning. It is a very singular characteristic of this pricking and smarting that it is much increased by holding the hand high above the head, and entirely relieved by holding it down. That is, draining out the blood increases the pricking, whilst filling the part with blood relieves it, and replaces it by a sense of fullness and numbness. The sensibility of the surface is very much diminished or lost, but this loss does not extend below the immediate surface. In ten minutes after the surface is dry, the whiteness and shrivelling disappear gradually, but the numbness and anæsthesia remain, or disappear much more slowly.

The 2 per cent. solution is too strong for such applications, and must be diluted by the addition of from one to two parts of water at the time of using it. One part solution and one part water for the thicker and less sensitive surfaces of adult males, and one part to two of water for the more delicate surfaces of women and children, the strength being adjusted to each case. If applied too strong the pain will, after a time, recur, or be increased, and if too weak will be but imperfectly relieved, but either the one or the other extreme can be surely determined if the part can be alternately held high and low, for if the pain be from applications too strong it will be increased on elevating the part and diminished on holding it down. But if the pain be from the burn through the application of solution too weak to control it, it will be increased by holding the part low. The best, and indeed the only proper way of applying the solution to burns, erysipelas, etc., is by very thin cloths—such as old worn muslin or handkerchiefs. A saucer is kept by the side of the patient supplied with the proper dilution for the case, and the cloths are wetted from time to time as indicated by the return of pain. If the burn be a grave one or the pain severe, the cloths should be frequently changed during the first few hours at least. Later the cloths may be covered with light oiled silk, so that the patient may not be disturbed during sleep. In slight burns or scalds of fingers, hand, wrist, etc., it is often sufficient to wrap the part in the thin cloth, and keep it wet without changing it, putting the oiled silk over the dressing only at night, to prevent evaporation. If the strength be properly adjusted to the case, and the solution be properly applied, the pain will always be relieved within ten minutes.

TESTING SUBNITRATE OF BISMUTH FOR ARSENIC, ETC.*

H. Hager publishes the following directions for testing subnitrate of bismuth, which we find in the *Pharmaceutische Centralhalle*:—

The preparation should dissolve completely to a clear solution in nitrate acid of 1·185 spec. grav. Now, it happens that the subarseniate of bismuth also forms a clear solution with pure nitrate acid of this strength, but not when the acid is saturated with subnitrate of bismuth. It requires eight parts of this acid to form a clear solution of one part of subnitrate of bismuth in fifteen minutes. If 0·5 gram of the subnitrate is treated with 4 grams of nitric acid, and does not dissolve in half an hour with occasional shaking, but is either turbid or exhibits a slight opalescence when viewed from above, it contains arsenic; a considerable quantity in the former case, in the latter but little. All commercial samples that I have tested were contaminated with arsenic.

The optical test for arsenic acid is easy, and can be made even by those who are not chemists. It depends on the fact that arseniate of ammonia is not decomposed by heat into its two components, but rather undergoes an elementary decomposition, turning brown. The test is made as follows, and at the same time it may be tested for alkalies. About three or four grams of caustic ammonia are poured upon a gram of subnitrate of bismuth, and warmed from 30° to 40° C. (86° to 104° F.), and shaken, then filtered while warm. Arseniate of ammonia dissolves with difficulty in cold ammonia, but easily in warm. One or two drops of the filtrate are placed on a thin watch glass, and heated by moving it to and fro

* From the *Druggists' Circular and Chemical Gazette*.

over the chimney of a kerosene lamp, as long as vapours are noticed, that is, until all the nitrate of ammonia has been driven off, and a few minutes longer. On examining the residue with transmitted light, if arseniate is present a brownish colour will be observed, which becomes dark brown on the edges of the spot. Under the microscope dark grey or brown masses may or may not be seen here and there. If not, it must be heated still more. The colour of the spot as seen with the naked eye is sufficient. If potash or soda were present, the spot will not disappear on heating strongly. This experiment is entertaining and instructive, for remote traces of arseniate can be easily recognized in this way.

The test for alumina and other earths can be made in a similar manner by pouring 1½ gram of dilute acetic acid upon a gram of the bismuth preparation, warming, and when cold adding 5 c.c. of caustic ammonia with 2 c.c. of water, shaking for three minutes, filtering, evaporating the filtrate, and neutralizing with carbonate of soda. If it remains turbid, earthly salts were present.

METHOD FOR DETERMINATION OF NITROGEN.*

BY J. KJELDAHL.

The author shows the desirability of a process for effecting the determination of nitrogen in the moist way. He criticizes the process of Wanklyn and Chapman, and proposes in its stead an oxidation in an acid solution.

The sample to be operated upon is first strongly heated with sulphuric acid; and is thus almost invariably brought into such a state that its nitrogen is completely converted into ammonia by the following operation. The principle of the process is treatment with a sufficiency of concentrated sulphuric acid at a temperature not much below the boiling point of the acid. The solution thus obtained is oxidized with an excess of dry powdered permanganate. Under these circumstances the organic nitrogen is completely transformed into ammonium sulphate; the liquid is then supersaturated with soda, distilled off and determined according to the usual methods.

It is essential for this process that ammonium sulphate, at the high temperature applied, and especially during the subsequent treatment with permanganate, which is attended with a very violent reaction, does not undergo decomposition. This the author has ascertained by special experiments.

The procedure may be described as follows:—The substance is weighed into a small, tared boiling flask, in which the further treatment is to take place.

Even with solids this is a very convenient arrangement, but still more so with liquids. A liquid is weighed in, the water allowed to fly off in the evaporation niche, when the extract remains where it is wanted. Oil of vitriol is then added in a sufficient excess. The quantity may vary within tolerably wide limits, though the author always employs 10 c.c. Great care must be taken that the acid does not absorb ammonia. The author has often found traces of nitrogen in the so-called pure acid of commerce, for which a small correction must be made.

The flask is then placed upon a piece of wire-gauze over a small gas flame. As a rule the contents become back and tarry, but on continued heating a brisk reaction sets in with escape of gas, during which the substance is completely dissolved. On account of the escape of sulphurous acid and of white fumes this operation should be conducted under a draught hood. To prevent loss by spirting the flask should be set in a slanting position until the contents are come to rest. The flask should hold about 100 c.c. and have a long narrow neck. When the escape of gases has ceased the action of the sulphuric acid is not at an end; a slow oxidation goes on; the liquid first becoming a deep brown, then light brown, yellow and ultimately clear as water. To accelerate this process a little fuming sulphuric acid or phosphoric anhydride is added. With these additions a heating for two hours is sufficient to give a clear light brown liquid. With the albuminoids and their derivatives the formation of ammonia is as complete after heating for 1–2 hours as if the liquid had been rendered almost colourless by prolonged treatment. With other substances, such as are mentioned below, the addition of phosphoric anhydride is recommended, and heat is applied until the disappearance of the colour indicates that the action of the acid is at an end. The temperature should be a little below the boiling-point of the acid, as is indicated by occasional "bumps." At temperatures of 100°–150° the formation of ammonia is exceedingly imperfect. The substances for analysis do not require pulverization further than is needed for obtaining a correct average portion.

The oxidation is then effected by means of permanganate, for which no efficient substitute has been found. It is applied in the state of a fine, dry powder, which is introduced in very small portions which may quickly follow each other. The oxidation is effected in the hot liquid, though the flame is removed, and is completed in less than a minute. Although the reaction is violent and is even accompanied with small flames, there is never a loss of ammonia. The completion of the process is indicated by the appearance of a green colour. The author generally allows the flask to stand over a very gentle flame for five to ten minutes, without ascribing especial importance to this procedure. On no account must a strong heat be applied to the green liquid, as this would involve a serious loss of ammonia.

The liquid when sufficiently cool is diluted with water, when the green colour changes to a brown. When again cool it is introduced into the distillatory apparatus, which should hold about ¾ litre, and is connected with a top-piece sloping upwards to ensure the reflux of any spirts, and connected with a spiral condenser leading into an absorption apparatus charged with standard acid.

The soda lye used has the specific gravity 1·30, of which 40 c.c. are rapidly introduced into the distillatory apparatus and the stopper re-inserted. There is no perceptible loss of ammonia in this operation, and consequently no special arrangement is necessary for the introduction of the alkali.

To prevent bumping in distillation, small zinc turnings or filings are introduced before the addition of the alkali.

For substances containing about 1·5 per cent. of nitrogen, the author operates on 0·7 gram; for richer bodies, ¼ gram. The results obtained by the new method agree very closely with theory and also with the figures obtained by Will and Varrentrapp's process. In connection with this process the author has obtained good results in the analysis of the alkaloids by omitting, as usually recommended, to form a channel extending along the entire combustion tubes by gentle rapping. He considers that the danger of loss by the formation of nitrogenous vapours, which are not taken up by the acid, is greater than that of the dissociation of ammonia which is so often brought forward. For further security he adds a little pure sugar to the soda-lime at the front end of the tube. Whilst the soda-lime sinks together when heated and leaves an open way between itself and the sides of the tube, the sugar on combustion forms a porous carbonaceous mass which fills the entire width of the tube, and through which all the gases formed by the combustion of the substance are obliged to pass.

The author, when recommending his method for organic substances in general, with a certain reserve as regards some alkaloids, admits those bodies as exceptional in which the nitrogen occurs in the form of volatile acids, such as, generally speaking, the cyanides and the oxides of nitrogen. As regards the nitrates a peculiar fact must be put on record. Whilst it might be expected that the nitric acid would be in great part volatilized by heating

* From the *Zeitschrift Analyt. Chemie.* Reprinted from the *Chemical News.*

for hours with concentrated sulphuric acid in large excess it is found, on the contrary, that the greater part of the nitric acid in presence of organic matter is converted into ammonia.

GUM ACACIA.*

Gum arabic should be regarded as a generic name, while acacia is a specific name properly applied only to that kind of gum arabic used in medicine. The gum arabic from which acacia is selected comes chiefly from Kordofan, down the Nile, in sacks, to Cairo, Alexandria or Trieste. In this original condition it is called gum arabic "in sorts," that is, unsorted or unseparated. The fragments are of all shades of colour lighter than a very dark amber, and are contaminated with bark, dust, etc. At the three points mentioned the gum arabic is picked —women, children and cripples being employed in picking it, and at Trieste especially, the picking constitutes quite a large and important industry. This picking separates the fragments by colour and by freedom from adhering bark, etc., into about five grades usually, and these are called, technically, in commerce, "first picked," "second picked," "third picked," and so on, and these grades are then fitted for their special uses chiefly in the arts for "sizes" and "bodies" and in confectionery. The first and second picked are very nearly colourless, and only differ in colour by a shade or two, but the second picked is not so free from adhering specks of bark. The first three or four of these grades come into the markets in cases containing about 136 kilogrammes or 300 pounds each. The other grades come in bags. Of these grades the first picked only should constitute the acacia of the Pharmacopœias, and to this grade only does the name "Acacia" and the U.S.P. officinal description properly belong. It is, therefore, not "Gum Arabic," but is "Acacia," selected by picking as the best and purest part of gum arabic. It is true, however, that this grade is rarely bought for medicinal uses, the second and third picked, which are considerably cheaper, being generally used. If not seen together, few buyers can distinguish between "first picked" and "second picked," so that sellers by keeping the "first picked" out of their assortment are easily able to sell second for first, and so on down.

Other varieties of gum arabic come down the Nile which are well known in commerce, but the sources of which are not well determined. They are not distinguishable in appearance from the gum just mentioned, and go through all the process of picking exactly as do the other gums, and they appear in the markets together, and in "first hands," that is, in the pickers' or in the large importers' hands, the cases are seen side by side, but after leaving "first hands" the distinctions between these and true gum arabic are commonly lost. These gums are, however, of inferior quality, and are sold at a lower price. A few years ago the difference in price amounted to 20 to 25 per cent., but of late the true gum arabic has fallen somewhat in price, and now the difference is hardly greater than 10 per cent. These inferior gums have been variously called "Gum Sennaar," or in the market "Senare," "Ghezireh" and "Gedda," probably from the districts in which they are collected; the latter name being the most common, and now pretty generally applied to the whole clas of these inferior gums.

"First picked Arabic" and "First picked Gedda" are often undistinguishable even by experts, unless seen together and closely compared, and hence the cheaper is often substituted for the better and dearer gum, and still more frequently is mixed with it as an adulterant. The chief characteristic of these poorer gums is a sour smell, which, though easily recognized in the "sorts" or in the lower grades, is by no means easy in the first and second picked. Generally, however by brushing off the surface gum from the top of a case, and plunging the hands down so as to bring up a double handful from near the middle of the case, the sour odour can be detected. But if 10 or 20 per cent., of the gedda only is mixed with the true gum, it is almost impossible to detect it.

The inferiority of these gums is that they make a thinner and poorer mucilage than the true gum, and a mucilage which changes and sours sooner. The expression in the arts and in confectionery is that it "does not go so far,"—"does not make as fine a stock," and causes loss by spoiling more easily. The inference drawn by the writer from these circumstances is that these gums come from districts which are subjected to showers, or to some form of dampness which is sufficient to start a slight fermentation in the gum itself. This hypothesis is strengthened by the circumstance that a bag of fine gum which accidentally gets wet soon develops this sour smell, while others of the same lot will have the natural freedom from all smell or have the very faint, clean, sweet smell.

The uses of acacia in medicine require it in two forms, namely, in solution and in fine powder. The solution is used in various ways and for many purposes, and is officinal in the forms of a mucilage and a syrup. The mucilage contains 34 per cent. of acacia, and the syrup about 8 per cent. The solutions do not keep well, especially when there is any admixture of gedda in the acacia, or when there is the least quantity of old solution left to start the souring of the new, and therefore they should always be freshly made. To make a good solution promptly not only requires some skill, but also requires that the acacia be in a proper condition. Taking the acacia in its officinal condition the solution of the fragments is a very slow process. If it be rubbed up in a mortar enough of it goes into fine powder to make the whole clog together, and then again the process is tedious and troublesome, whilst if fine powder be taken there will be still more difficulty and the loss of more time.

Many years ago the writer made a series of trials to determine the condition best adapted to making easy and rapid solution, and the result was that a granulated acacia in the form of a coarse powder free from any fine powder was all that was needed, and a "Granulated Acacia" has been supplied to the markets ever since, and is now in common use. This is made by coarsely grinding the first picked true acacia until it all passes through a No. 50 sieve. The finer particles are then all taken out of this coarse powder by careful and thorough use of a No. 80 sieve. This leaves a very uniform, clear, coarse powder, which constitutes the granulated acacia. That which passes through the No. 80 sieve is again ground in a finer mill and passed through bolting cloth No. 120, and constitutes the powdered acacia, adapted to a different class of uses. The granulated acacia is so promptly soluble that it cannot be washed with cold water, as directed by the Pharmacopœia under the head of Mucilage of Acacia, nor is the washing needed, as the mucilage will be opalescent in either case and not very different. It is, however, true of acacia, as of other drugs, that the grinding does render the solutions more opalescent, because the particles of bark, etc., which are insoluble are ground up very fine, and because the attrition grinds off fine particles of the mill surfaces. From these circumstances it comes that the finer the powder the more opalescent the solutions made from it.

The uses of acacia in medicine are chiefly as a vehicle, a diluent or a demulcent. It is also, doubtless, an aliment of the very simplest and blandest kind. In all these offices or functions it has many duplicates and substitutes, but yet stands at the head of its class, though its advantages are often overlooked through the popular appetite for novelty and change.

As an adjuvant or corrigent for prescription uses, whether in solutions or in powders, it has no superior and perhaps no equal in covering the taste of disagreeable medicines, or in shielding the mucous surfaces against the sudden effects of acid or irritant substances, and its skilful application to its appropriate uses is too much neglected.

* From Dr. Squibb's *Ephemeris*.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 15, 1883.

MILITARY PHARMACY IN AUSTRIA.

IT cannot be said that in this country pharmacy enjoys an excess of recognition on the part of the military authorities. In the naval service there are a certain number of appointments as dispensers and keepers of medical stores in the principal naval hospitals which are open solely to qualified pharmacists; but in the army an appointment as compounder of medicines can only be obtained by an indirect process which involves a previous enlistment as a private, followed by promotion to the rank of sergeant. In France, however, where they manage things differently, the *pharmaciens-militaires* have for nearly a century constituted an important independent organization, which about ten years ago was able to resist successfully an attempt to place it under medical control. When the French army was reorganized after the Franco-German war, this corps was augmented to one hundred and eighty-five members, consisting of an inspector, eight principals of the first-class and sixteen of the second, forty majors of the first-class and fifty-five of the second, and fifty aides-majors of the first-class and fifteen of the second. Turning to another important continental country, the recent exhibition in Vienna has furnished evidence that the connection between the trained pharmacist and the supply of medicines to the army is an object of considerable solicitude to the War Department of the Austrian empire, and some information upon the subject of the military pharmaceutical department has been supplied to our contemporary, the *Pharmaceutische Post*, by a writer evidently well acquainted with the working of the system at present obtaining in that country, which appears to be of sufficient general interest to warrant the transference of a portion of it to these columns.

The Austrian "Military Medicament Branch" belongs to the regular army establishment, and has for its object the maintenance of a stock of medical substances, instruments and utensils, corresponding to the requirements of the army in times of peace or of war; also to provide for the preparation of medicines according to the directions of the 'Military Pharmacopœia,' to supply the same to the troops and different medicine stations, or to individual patients under medical direction, and to keep the necessary accounts. At the head of the Branch is a Director, and in times of peace he has under his control eight Superintendents, seventeen subordinate officials of the first-class, eighteen of the second-class, and eighteen of the third-class, and eight attendants. The nomination of the Director and of the Superintendents is reserved to the Emperor himself, but the appointment of the other officials is made through the Minister of the War Department. In respect to position, the Director is at the disposition of the chief of the medical department of the army, and any proposals that he may wish to submit to the ministry of war have to pass through that channel. His duties comprise a general supervision of all the operations of the department. The Superintendents and officials of the higher class are usually entrusted with the management of the business in the larger medicament depots. In time of war the official body is multiplied five or six times, by drafts from one-year volunteers possessing the grade of "Magister der Pharmacie" who have been placed in the reserve, and who, after having satisfactorily passed a military-pharmaceutical examination, are nominated as military medicament officials in reserve. In time of peace the permanent military medicament establishments under the direct management of the Director are one principal depot, in connection with which there is a laboratory, twenty-six pharmacies in garrison hospitals, and ten garrison pharmacies. Other medicine establishments are, without prejudice to the superior control of the Director, more or less subordinated to various authorities with whom they come into contact. All these establishments are supplied with materials for medicines and medical instruments, etc., from the central depot. Upon the mobilization of any part of the army for operations a field depot is established, from which all the medicines required for the division are supplied to the sanitary department. The outline arrangements as to the quality and distribution of medical stores are made by an Inspection Commission, consisting of medical officers of the army and the Director of the Medicament Branch, and this Commission also determines the quantity and other conditions as to the medical materials and necessaries to be provided. The drugs required are regularly purchased once a year by written tenders from competing commercial houses and the raw materials are worked up in the laboratory attached to the central depot in Vienna, which is well provided with machinery and apparatus.

In concluding this brief sketch it may be mentioned that the characters of the drugs and the nature of the medical preparations issued by this department for use in the Austrian Army are defined in a special 'Military Pharmacopœia.' The first of these works was issued as far back as the year 1795, and is described as having been a treasury of the most wonderful mixtures and antiquated remedies. The second appeared in 1820, and it marked a decided advance in the scientific direction, many of the drugs and formulæ contained in the first being now omitted.

In 1840 a third military pharmacopœia was published, in which a list of reagents and veterinary medicines were included for the first time, whilst in 1859 this gave place to a fourth, which was fundamentally different from all its predecessors and was written in the German language instead of the Latin. Lastly, in 1872 the fifth edition appeared, and this remains in force at the present time. The principal object sought to be attained in this work appears to have been the production of active reliable medicines, occupying a comparatively small space and as little susceptible as possible to damage through rough treatment in transport or variations of temperature.

It may be useful to remind our readers who are pharmaceutical chemists and who wish to avail themselves of the exemption from jury service to which they are entitled, as to the desirability that they should without delay examine the lists of jurors which will remain suspended on the doors of all places of public worship in England and Wales until Sunday next, in order to ascertain whether their names have been improperly included as liable to serve. Should this be the case in any instance an application to have the name expunged should be made on the day of appeal, the date of which is announced on the list, and a certificate of registration may be obtained from the Registrar to produce in support of the claim. Should the claim not be made, the defaulter will be liable to be called upon to serve as a juror as long as his name remains on the jury list.

* * *

The Thirteenth Annual General Meeting of the German Pharmaceutical Association, which was held last week in Wiesbaden, was very numerously attended. On Thursday afternoon upwards of six hundred ladies and gentlemen sat down to dinner together in the great hall of the Kurhause, and on Friday nearly an equal number went on an excursion to the Niederwald.

* * *

In the afternoon of the last day of the recent exhibition in Vienna it was visited by the Archduke Carl Ludwig, who was prevented by illness from being present at the opening. His Imperial Highness made a prolonged and careful examination of the different cases, and manifested considerable interest and curiosity respecting many of the articles shown. At the close of his inspection he received the members of the executive committee and jurors who were present. In the course of a conversation with a recent President of the Pharmaceutical Society, the subject turned upon the probable locality and date of the second international pharmaceutical exhibition, and a hope was expressed that it would be held in London within three years.

* * *

It is announced on good authority that although the accounts of the Vienna exhibition have not yet been finally closed, the Executive Committee has felt itself warranted in paying over the sum of five thousand florins to the credit of the pharmaceutical benevolent fund of the "Hygiea" association.

* * *

Apropos of exhibitions it may be mentioned that for some time past there has been a growing opinion that the holding of a pharmaceutical exhibition every year in connection with the annual meeting of the German Pharmaceutical Association was undesirable. The subject was brought before the recent annual meeting by the presentation of a memorial to that effect, and it was resolved that the practice of holding exhibitions at such short intervals should be discontinued.

* * *

If we may judge from a courteous invitation that has reached us, the American Pharmaceutical Association, which has this week been meeting in Washington, has had its attention pretty equally divided between work and recreation. On Tuesday it was to meet at 3 p.m., to hear the President's Address, and the evening was to be devoted to a Concert. On Wednesday, three hours were to be spent in the election of officers and receiving the reports of committees and the remainder of the day in visiting an exhibition and various institutions, winding up with a Reception and a Ball. The morning of Thursday was to be occupied in visiting more public institutions; the reading of papers was to take up three hours in the afternoon; and "at 6.30 sharp" there was a Banquet, with "music, toasts and accessory pleasures." On Friday morning three more hours were to be spent in reading papers and in the afternoon there was to be an excursion on the Potomac, with "music and lunch," at the invitation of the local committee. On Saturday there were to be various excursions arranged by the Entertainment Committee.

* * *

There is one point in connection with this meeting in which it will differ markedly from the meeting of the British Pharmaceutical Conference in Southport next week and which is worthy of the consideration of the leaders of the British society. Every attendant at the meeting of the American Pharmaceutical Association expects to contribute towards the expenses incurred and on the present occasion coupon tickets for all the events arranged on the programme, price five dollars for each person, were issued by the General Entertainment Committee, and no person was admitted without one. For the complimentary excursion at the invitation of the local committee a special ticket was issued.

* * *

We learn from the *Medical Press and Circular* that it has been arranged by the Council of the Social Science Association that in the course of the meeting which is to commence in Huddersfield on the 3rd of October, there shall be a discussion on the question of "legislative enactment in the direction of amendment of the Sale of Poisons Act," which will be introduced by Mr. Meymott Tidy. We have reason to believe also that a legal gentleman is preparing a paper on the question for the same meeting. It is to be hoped, however, that if it be intended to make the discussion a really serviceable one in forming public opinion, those who aspire to direct it will make themselves acquainted both with the existing law and the proposals that have been put forward for its amendment by the Council of the Pharmaceutical Society. But it cannot be said that the title attributed to the Act which at present regulates the sale of poisons in this country suggests a very intimate acquaintance with the subject.

* * *

We regret to have to announce the death, on the 7th instant, at the age of seventy-six, of Mrs. Margaret Sophia Bowen, who was elected as an Annuitant on the Benevolent Fund in 1881.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, September 5, at the College of Physicians, Kildare Street, at three o'clock.

The President, Professor Tichborne, in the chair.

The other members of the Council present were—Messrs. Brunker, Draper, Allen, Grindley, Hodgson, Simpson and Wells, Dr. Collins and Dr. Montgomery.

Mr. Fennell, the Registrar, read the minutes of the last meeting, which were confirmed.

A letter was read from the Secretary to the British Pharmaceutical Conference, requesting the Council to nominate gentlemen as delegates to the Conference which is to be held at Southport on September 18 and 19.

On the motion of Mr. Hodgson, seconded by Dr. Collins, Messrs. Payne, Minchin, Brunker and Wells were appointed delegates.

A communication was received from Mr. T. R. Lester, of Cork, presenting prescriptions to the Society.

The Registrar was directed to acknowledge the receipt of the prescriptions, and to thank the donor.

Letters were submitted from Mr. Patrick Joseph Finnegan, asking the Council to exempt him from the operation of the new rule requiring four years' study of practical pharmacy. The letters were dated from the dispensary connected with James's Gate Brewery, Dublin. The writer stated that he presented himself at the Society's Preliminary examination, held in October, 1882, but failed to pass. Subsequently the Council passed the resolution requiring four years' apprenticeship instead of two as previously. He passed his Preliminary at the next examination. A year and a half ago he entered himself as an assistant in the dispensary and had since served there. At the time he entered he did so on the faith that a certificate from the dispensary would be available for the Pharmaceutical Society; otherwise he would have entered at the Apothecaries' Hall. Afterwards he accidentally discovered that that certificate was not available because the dispensary was not an open shop. Then he made arrangements for a two years' apprenticeship, and he submitted as he entered under the old system under which only two years' apprenticeships were required, and as the resolution of the Council of the Society altering the requisite period had not yet been confirmed by the Privy Council, his present application might be granted, more especially as when he should present himself for his final examination two years hence he would have completed three and a half years. He also submitted that he ought not to be placed under a disability by reason of the Council not having considered his case.

Mr. Draper: He is wrong there, for his case was considered and it was decided that the new rule should not be retrospective.

The President: The new rule has not been approved of by the Privy Council yet.

Mr. Grindley: The new regulation has no force until it is confirmed by the Privy Council. I think his two years should be accepted.

Mr. Wells: But if the Lord Lieutenant sends back the resolution of the Council confirmed, then all who passed the Preliminary examination after January last will come under it.

Dr. Collins: Does he say that he is bound to a pharmaceutical chemist for three years?

Mr. Brunker: No, he speaks of making arrangements for that purpose

Dr. Collins: If he serves two years in an open shop we might give him credit for the year and a half in the dispensary.

Mr. Brunker: But if you give him a privilege not warranted by the regulations, how can you bind the Council that will be in office two years hence? We may take it for granted that our amended resolution introducing the new rule will be confirmed by the Privy Council.

The President: You can only meet his case by saying that a man who had entered into an apprenticeship before the confirmation of the rule shall be exempted from its operation.

Mr. Brunker: But are we going to ask the Privy Council for another amendment of our resolution? If we do that they will say that we do not know our own minds.

Dr. Collins: Would it be necessary to refer to the Privy Council at all in his case?

The President: He states that he is conforming to your present regulations. I think you must postpone the consideration of this case until you hear from the Privy Council.

Mr. Brunker: He has not conformed to them.

Mr. Grindley: But he is about to do so.

The President: The Privy Council might intimate to us that they confirmed our new regulation with the proviso that every man who had been previously apprenticed should be exempted from its operation. If that should take place he would be in a right position.

Mr. Brunker: If you open any loophole for escape from your new rule you will be flooded with applications. The speaker called attention to the terms of the resolution of the Council passed with reference to the new regulation, viz.:—"Every candidate for the licence who has not passed the Preliminary examination previous to January 3, 1883, shall be required to produce a certificate of a pharmaceutical chemist or apothecary keeping open shop, stating that he has served a *bonâ fide* apprenticeship of four years as apprentice or assistant in the sole employment of such pharmaceutical chemist or apothecary."

After some further discussion,

The Registrar was directed to write to Mr. Finnegan, stating that the consideration of his letter had been necessarily postponed.

Mr. Brunker moved the following resolution:—

> "That Mr. Fennell be directed to ask the Clerk of the Privy Council whether the resolution of January 3, last, as amended by the Privy Council, and accepted in its amended form by this Council on June 6, has yet been finally confirmed, and to inform him that inconvenience has arisen from the matter being still open."

Mr. Wells seconded the resolution, which was unanimously agreed to.

Some conversation followed upon the subject of the stopping of the supply of the *Pharmaceutical Journal* to members in accordance with a resolution passed by the Council, a report of the Law Committee was read and adopted.

Mr. Draper and Mr. Hodgson reported progress with respect to the fitting up of the Society's new premises in Harcourt Street.

Some financial business having been disposed of, the Council adjourned.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Executive Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on September 7, at 12.45 p.m.

Mr. John Harrison (Sunderland), President, in the chair.

Mr. W. G. Cross (Shrewsbury), Vice-President.

Present:—Messrs. Andrews (London); Arblaster (Birmingham); Barclay (Birmingham); Chapman (Scarborough); Churchill (Birmingham); Hampson (London); Holdsworth (Birmingham); Jervis (Sheffield); Jones (Llanrwst); Laird (Edinburgh); Mason (Liverpool); Parker (Nottingham); Symes (Liverpool); Walker (Coventry); Williams (Manchester); Yewdall (Leeds); and the Solicitor of the Association.

The minutes of the previous meeting of the Executive were read and confirmed.

Communications were read from Messrs. Bell, Ellinor, Mackenzie and Paterson, regretting their inability to attend.

The Secretary said that at the last Annual General Meeting a resolution was passed ordering a memorandum to be presented to the House of Commons on behalf of the Association, in support of the claim of pharmacists to be associated with the members of the medical profession in a legally constituted committee, for the purpose of preparing the British Pharmacopœia; that he had therefore prepared a petition which had been presented to the House of Commons in June last, by the President of the Board of Trade.

The petition was based upon and practically identical with the Memorial of the Council of the Pharmaceutical Society to Her Majesty's Privy Council (See *Pharm. Journ.*, [3], vol. xiii., 963.)

The Secretary also reported that he had addressed a circular to the members of the General Committee, and to each local secretary of the Association, enclosing prints of the petition, and asking them to forward a copy to their local Member or Members of Parliament, with a letter requesting support in the House of Commons to the prayer of the petition. He laid on the table numerous replies that had been received from Members of Parliament, which were, almost without exception, favourable.

The report of the Sub-Committee appointed by the Law and Parliamentary Committee to deal with urgent cases was then read. The report stated that the Sub-Committee had authorized the Solicitor to defend a member of the Association, residing at Aberdare, in proceedings instituted against him by the Inland Revenue authorities, for having sold, it was alleged, spirit of wine and methylated spirit without a licence. On investigation it had been found that the spirit of wine was strongly camphorated, and that the methylated spirit contained, when purchased by the defendant, the requisite quantity of gum. The cases, however, were not taken into court, as the defendant preferred to settle the matter by the payment of a small penalty which the excise authorities intimated that they were willing to accept. The Sub-Committee had also instructed the Solicitor to apply for an adjournment of certain cases under the Sale of Food and Drugs Act, which took place at the Marylebone Police Court on August 15, last, in order that samples left with the defendant by the Inspector might be analysed by the Analytical Referee of the Association.

It was moved by Mr. Symes, seconded by Mr. Mason, and unanimously resolved:—"That the Report now read be received, adopted and entered on the minutes."

It was moved by Mr. Holdsworth, seconded by Mr. Mason, and unanimously resolved:—"That the officers of the Association, together with Messrs Andrews, Arblaster, Barclay, Bell, Chapman, Jervis, Hampson, Parker, Symes and Walker, form a Law and Parliamentary Committee for the ensuing year."

It was moved by Mr. Andrews, seconded by Mr. Chapman, and unanimously resolved:—"That the officers of the Association, together with Messrs. Arblaster, Barclay and Holdsworth, form a Finance Committee for the ensuing year."

It was moved by Mr. Laird, seconded by Mr. Parker, and unanimously resolved:—"That the officers of the Association, together with Messrs. Andrews, Arblaster, Barclay, Bell, Chapman, Ellinor, Hampson, Holdsworth, Jervis, Jones, Maltby, Mason, Parker, Symes, Walker, Williams and Yewdall, form a General Purposes Committee for the ensuing year."

The following appointments were then made for the ensuing year:—Mr. Henry Glaisyer was re-appointed Solicitor to the Association; Professor Attfield was re-appointed Analytical Referee to the Association; Mr. W. F. Haydon was re-appointed Secretary to the Association on the same terms as before; Mr. Alfred Wright was appointed Assistant-Secretary to the Association, the engagement being terminable on three months' notice from any date, security to be given to the extent of one hundred pounds; Messrs. Lloyds' Banking Company were re-appointed Bankers to the Association; Messrs. Laundy and Co., Public Accountants, were re-appointed Auditors to the Association.

The Secretary then reported the circumstances attending the issue of summonses under the Sale of Food and Drugs Act against three members of the trade, two of whom were members of the Association, and after discussion, resolutions were passed as to the steps to be taken in defence by the Solicitor to the Association.

The President said the next question on the agenda paper was to consider the means of carrying into effect the following resolution, passed at the last Annual Meeting of the members of the Association:—"That as it is most desirable that chemists and druggists generally should be united in support of a Pharmacy Bill, it be an instruction to the incoming Executive to arrange an interview with the Pharmaceutical Council to promote that object."

In reply to a question, the Secretary said that from a correspondence which had taken place between Mr. Bremridge and himself in March last, it appeared that the amendments to the Pharmacy Acts Amendment Bill formulated by the Executive Committee of the Association had been laid before the Council of the Pharmaceutical Society, and had by them been referred to their Law and Parliamentary Committee for consideration. The last communication he had received from the Secretary of the Pharmaceutical Society was dated March 14, 1883, and intimated that Mr. Bremridge was unable to state when the Law and Parliamentary Committee of the Society would meet, as he had received no instructions to summon it, and that he was unable to give any particulars as to the probability of the Bill being introduced into Parliament at an early date, as no communication had been received from the Privy Council respecting it beyond the official acknowledgment of its receipt.

Mr. Holdsworth asked if no further communication of any kind had been received from the Pharmaceutical Society since the 14th of March last in reference to the Bill.

The Secretary said none whatever.

Mr. Symes said he thought some action should have been taken by the Association before the Bill was sent by the Pharmaceutical Society to the Privy Council, as it was no secret that the Bill was being prepared, and the Association had every opportunity of expressing its views.

The Secretary said the contents of the Bill were not made known to the Association until after the Bill had been printed and a copy transmitted to the Privy Council. The Executive had taken the earliest possible opportunity at their command to examine the provisions of the Bill and report to the Pharmaceutical Council amendments they considered desirable.

Mr. Barclay said it would be remembered that at the last Annual Meeting there was a general expression of opinion that the Association had not had sufficient opportunity for making known their views with regard to the amended Pharmacy Bill. A suggestion had been made that the Association should ask for an interview with the Pharmaceutical Council.

The President said he thought the present a favourable time for the interview.

Mr. Hampson said he believed the Pharmaceutical Council were as anxious as the Association that there should be unanimity, and a Bill carried, which would be equally acceptable to both bodies. The Executive, however, had no idea of the immense labour which had been bestowed upon the present Bill by the Council.

After some further discussion, it was moved by Mr. Barclay, seconded by Mr. Mason, and unanimously resolved:—"That as it is most desirable that chemists and druggists generally should be united in support of an Amended Pharmacy Bill, the Secretary be instructed to write to the Secretary and Registrar of the Pharmaceutical Society to arrange an interview between the Pharmaceutical Council and a deputation from this Executive before such a Bill is introduced into Parliament.

Some considerable discussion took place as to the advisability of urging the Board of Inland Revenue to issue an order making it compulsory on excise officers, when purchasing spirit for analysis, to leave with the seller a portion of the article purchased, as a protection in the event of errors being made by the officials who subsequently deal with the spirit.

The President said that he thought it was extremely desirable that action should be taken in the matter for the protection of the trade, more especially as he believed that one half the penalty recoverable under proceedings of that nature went to the informer.

It was moved by Mr. Symes, seconded by Mr. Parker, and unanimously resolved:—"That the Secretary be instructed to endeavour to arrange an interview between the Commissioners of Inland Revenue and a deputation from the Executive Committee of the Association for the purpose of urging upon the Inland Revenue authorities the advisability of issuing an order making it compulsory on excise officers, when purchasing spirit for analysis, to leave with the seller portion of the spirit sold."

It was moved by Mr. Jones, seconded by Mr. Barclay, and unanimously resolved:—"That in the event of the Commissioners of Inland Revenue consenting to receive the deputation, the President, Vice-President, and Messrs. Andrews and Hampson, with power to add to their number, be requested to represent the Association."

On the motion of Mr. Barclay, seconded by Mr. Mason, a number of gentlemen were then unanimously appointed Local Secretaries of the Association for the ensuing year.

Mr. Mason suggested that for the future a meeting of the newly appointed Executive Committee should be held in London on the same day as the Annual Meeting, for the purpose of appointing Committees.

The Secretary said the proposed arrangement would be unworkable, as persons not present at the Annual Meeting were frequently appointed on the Executive and would, therefore, be unable to attend.

Mr. Yewdall said that on looking through the last published list of members of the Association he found the names of several firms who subscribed in their collective capacity 5*s.* only. He thought annual subscriptions of 5*s.* should be paid by each member of the firm.

The Secretary said that 5*s.* had always been accepted as a subscription both for firms and individuals. If any alteration was now made he thought it should cover branch businesses, as the liability to the Association of a firm of two or three members with one business was not so great as that of an individual carrying on two or three businesses.

The President said that he did not think it advisable to make any alteration in reference to the subscriptions of firms, but that when collecting subscriptions, local secretaries might very well ask each member of a firm to contribute 5*s.* to the funds.

A communication was read from a member of the Association intimating that a person residing in Northamptonshire had taken out a hawker's licence and was selling from a traveller's van, drugs, patent medicines, etc., in the various villages in the locality. The Secretary was instructed to inquire into the matter, and in the event of his finding scheduled poisons were being so sold to take proceedings for the recovery of the penalties to which the individual was rendering himself liable.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Solid and Liquid Illuminating Agents.*

BY LEOPOLD FIELD, F.C.S.

Lecture VI.

It was stated in the last lecture, with regard to the formation of petroleum, that Berthelot's theory of a mineral origin could not be well entertained, inasmuch as the postulated degrees of heat and pressure could not be found at the depth at which the last traces of petroleum occur. It may be that a sudden decomposition of organic matter under heat and pressure, where the gases generated are confined in contact with the liquid products, would bring about the formation of paraffin and olefine. Of coal we know that it is formed from vegetal matter, and, to a vast extent, from drift and accumulation of spores. But this is not always a process of such infinite time as is generally supposed. Wood, bearing marks of human labour, has been found partially carbonized—witness the piles driven in by the Britons to retard Cæsar's advance, the outer surfaces of which had undergone a decided carbonization. We are in possession, too, of all the links which connect coal and green wood. Here are specimens of peat, taken at different depths, becoming denser and denser, and, at a depth of 14 feet, resembling lignite—though less dense—and only requiring pressure to reduce it to a true coal; and here the gradations from lignite through all the coal varieties to anthracite. We may suppose that cellulose $C_6H_{10}O_5$ (wood-fibre) is split up according to the equation—

$$2\,C_6H_{10}O_5 = 5\,CH_4 + 5\,CO_2 + C_2,$$

and this is well supported by the abundance of marsh gas and kindred hydrocarbons found in the vicinity of coal mines. The variation in constitution undergone by wood-fibre, while changing to coal is as follows:—

	Carbon.	Hydrogen.	Oxygen.
Wood	100	12·18	83·07
Peat	100	9·85	55·67
Lignite	100	8·37	42·42
Bituminous coal .	100	6·12	21·23
Anthracite . .	100	2·84	1·74

As I observed when speaking of petroleum, we cannot well form an idea of its true constitution, inasmuch as during distillation what is termed "cracking" takes place, *i.e.*, the splitting up of molecules, by which one equivalent of a dense hydrocarbon may yield two or more lighter members, perhaps even of different series. Certain it is that, by the rapid distillation of heavy oils at a high and sudden heat, products are obtained which could not have existed in the original substance. When paraffins are heated under pressure, both paraffins and olefines are formed—

$$C_{20}H_{32} = C_5H_{12} + C_{15}H_{30} = C_7H_{16} + C_{13}H_{26} = \text{etc., etc.}$$

All the known paraffins have been obtained from Pennsylvanian petroleum, and the olefines, $C_{10}H_{20} - C_{13}H_{26}$. The main difference between petroleum and shale oils lies in the amount of olefines contained, which preponderate in the shale oil, as would be supposed A gaseous petroleum consisted of 90 per cent. CH_4, 8 per cent. C_2H_6, and 2 per cent. H; while the gaseous products of distillation of shale, analysed by Coleman, gave C_4H_8, C_5H_{10}, and C_6H_{12}, all olefines. The paraffin hexane, C_6H_{14}, a main constituent of American petroleum, is closely allied to cellulose, $C_6H_{10}O_5$.

* Cantor Lectures: Reprinted from the *Journal of the Society of Arts.*

A more detailed formulation of the change would be—

Vegetable fibre	$C_{12}H_{20}\ O_{10}$	The equivalents have been doubled throughout, to avoid too small fractions,
Peat	$C_{12}H_{14\cdot4}O_5$	
Brown coal	$C_{12}H_{13\cdot}\ O_{3\cdot8}$	
Lignite	$C_{12}H_{11\cdot3}O_{3\cdot2}$	
Bituminous coal	$C_{12}H_9\ \ O_3$	
Asphalt	$C_{12}H_{7\cdot7}\ O_{1\cdot1}$	
Elastic bitumen	$C_{12}H_{22}\ \ O_{0\cdot15}$	
Petroleum	$C_{12}H_{24}$	

which last would be obtained by the whole of the oxygen being evolved with half its volume of carbon as carbonic dioxide, which would leave the proportions of carbon and hydrogen as shown.

But as, wherever wood is found in process of decomposition, the elements of hydrogen and oxygen are being evolved—as H_2O and CO_2—in such proportion to the carbon as would tend to leave the latter ultimately free—as in anthracite—we must conclude that the formation of petroleum from wood, if it ever took place, must have been carried on by some unknown and extinct process.

The following table shows the chief differences between the oils obtained severally from shale, petroleum, and coal tar:—

	Shale.	Petroleum.	Coal tar.
Naphtha	70 per cent. heptylene C_7H_{14}; various paraffins, *no* benzene	70 per cent. heptane C_7H_{16}; olefines *and* benzines	Almost entirely C_6H_6 (benzene)
Photogene	50 to 80 per cent. C_nH_{2n}, remainder $C_nH_2N+_2$	50 to 80 per cent. $C_nH_{2n}+_2$, C_nH_{2n}	—
Lubricating	C_nH_{2n}, and $C_nH_{2n}-_2$	Less C_nH_{2n}	—
Paraffin	$C_nH_{2n}+_2$, *no* vaselene	$C_nH_{2n}+_2$; wax (and vaseline)	—

We come now to the solid, and partly solid, or viscid forms of native bitumens, which are very numerous. Under the name of petroleum is understood now the liquid form of natural hydrocarbon, but there is little doubt that the viscid and solid forms, as asphalt, tar, and bitumen—I speak, of course, of natural products—are forms of petroleum which have undergone condensation, either before or after the destructive distillation or putrefaction, which we suppose to be the origin of petroleum. Such names as Rangoon tar, or Burmese naphtha, Barbadoes tar, Trinidad pitch, and the like, cannot be regarded as defining accurately the substances to which they are applied. It would be useless for me here to enter upon the difference in the chemical constitution of all these varieties, each of which has acquired a reputation rather due to the prolific nature of its special source than any particular merit. I will select Rangoon tar for a few moments' consideration, as it has a place in the early history of paraffin. You know that Mr. Rees Reece obtained paraffin on a large scale by destructive distillation of peat; and a small company was formed in 1850, for working that material. Although this company was unsuccessful, it was through its agency that the first paraffin candles were brought before the public. Now, in 1854, Dr. De La Rue took out a patent for purifying and working Rangoon tar, or Burmese naphtha. Price's Patent Candle Company took this up, and worked it on a very large scale. It is worthy of remark that, in 1859, they actually sent 10,000 gallons of their oil to New York, which would now, indeed, be equivalent to sending "coals to Newcastle." I do not know what paraffin was ever obtained from this material on a large scale, Dr. De La Rue's patent referring to its treatment with nitric acid, for separation of the olefines and benzenes. In 1851, medals were awarded to Young for paraffin oil from coal; to Wiseman, from shale; and to Moreau, from bitumen. At the Paris Exhibition of 1855, the works of Mont Auriol, near Paris, exhibited paraffin from resin, of which were distilled annually nearly 3000 tons. The amount of paraffin is, however, so small as to be useless on a large scale. It must be remembered that, although I have not mentioned lubricating oil with any particular emphasis, since it is extraneous to my theme, this is at least of equal importance with the solid paraffin and the burning oil. The amount of lubricants consumed is enormous, and, from the fact of their freedom from oxidation, absence of acid properties, and general immutability, are supplanting animal and vegetal oils in all directions. A great portion of the liquid bitumens from Burmah, Rangoon and Baku are devoted to producing lubricants. I stated, you will remember, that the attention of the Russians had been actively directed to the construction of a lamp that should burn their heavy oils, and we are told that considerable success has attended their efforts. They are reported as being able to burn oils from ·860 to ·910. The importance of this to Russia is very great, as the oil of Baku contains nearly three-fourths of its weight of such heavy oils.

Asphalt yields on distillation, both paraffin and paraffin oil; but its chief use is, as is well known, for road-making. Coming now to the solid forms of natural hydrocarbon, we have the remarkable mineral, ozokerit, which, within the last ten years, has become almost a household word. The localities where earth wax, as ozokerit is often called, is found, are exceedingly few; in fact, I may say, there is only one spot where the genuine mineral has been found in any quantity, and that is in Boryslaw in Galicia. There are, no doubt, in the neighbourhood, and perhaps at intervals along the shores of the Danube, sources of ozokerit, but, though hardly a week occurs without specimens passing through my hands from nearly all parts of the globe, and all purporting to be ozokerit, I have found none that could compare for a moment with that from Boryslaw. A great number of specimens are marl or sand, caked with thick petroleum, and yielding on distillation an almost worthless oil. I have placed on the table a number of specimens of natural bitumens, from the very lightest naphtha down to the purest ozokerit. You will, I think, find that there are few countries which are unrepresented. Professor Boverton Redwood, the Secretary to the Petroleum Association, has very kindly supplied me with samples of the chief kinds from the most noted sources, and the Rev. Urban Smith has contributed a collection which transcends in interest perhaps any on the table, inasmuch as it embraces specimens from Castleton in Derbyshire, the scene of Dr. Young's first discoveries. A very remarkable form of petroleum occurs here, namely, what is called *elastic* bitumen. You will see how remarkably resilient and indiarubberlike a body it is. Of its formation or age I am unable to give any idea, and only know that this variety has been found in but one other mine in France.

You have also, from the same spot, some very curious illustrations of the way in which petroleum occurs. Here, for instance, are long tubes, evidently formed from inspissated petroleum, and here a piece of rock, the holes of which are filled with a semi-solid bitumen. Here is some tar from Coalbrookdale, Shropshire, another ancient source of bitumen; and here again are a number of specimens of oils from Italy. Germany has recently developed a number of sources. At Oelhein, a light oil has long been found, closely resembling that of America, and at a great depth. In Bavaria, recent borings have been rewarded by a plentiful flow of light oil, rich in luminants and paraffin, which renders this variety equal to the best supplied by Pennsylvania; and in Alsatia and Austria springs are also being worked. It is singular that, with so many sources of liquid bitumen, there should be only this one spot which furnishes the solid variety, and that this should differ so widely from all the others; for, whereas the richest petroleum yields under 10 per cent. of paraffin, ozokerit, by proper treatment, can be made to give 80 to 90 per cent. In fact, there is little doubt that this mineral is nothing more than solid high-melting point paraffin, with very small percentage of oil and dirt. This large specimen of ozokerit, as it comes from the mine, has been selected for me by the largest company in Galicia, and is as good an illustration of the natural mineral as can be wished. The fine crystals which project from it in different directions are rock salt, which is never far off an ozokerit mine. The dark striæ are gypsum, infiltrated with a small amount of tarry matter. Cutting off a corner of this lump, you see, characteristic of the mineral, a deep golden yellow wax, giving by reflected light the greenish tint characteristic of all bitumens, which becomes more evident when the mineral is melted. As you see it here, although coated with the dirt of the mine, the ozokerit itself is nearly pure, all inorganic minerals traversing its substance in regular layers. By melting and clearing-down with a little acid these are readily removed. It is then cast into blocks of about one hundredweight each, which are either manufactured on the spot or exported. To obtain products from the mineral ozokerit which can be used commercially, one of two processes is resorted to. The first, which is most largely employed, is that of treating the crude wax with Nordhausen oil of vitriol, and heating it till the acid has become decomposed or evaporated. After proper decolorizing, the wax assumes a golden yellow colour, and in appearance much resembles beeswax. It is called *ceresin* from this resemblance, and can be brought almost to a pure white. Here are specimens of both white and yellow ceresin. This material, however, is not of much use for candle making, as it has a strong and unconquerable tendency to smoke, but its other uses are very great. It is largely employed as an adulterant of beeswax, in which, though, it can be readily detected by strong sulphuric acid, which decomposes the pure cerotate, leaving the mineral intact. To render ozokerit useful to the candle-maker, it has hitherto been necessary to distil it, although several patents have recently been taken out in which this process is discarded. Ujhely, who has devoted much attention to the working of earth wax, dissolves the crude material in benzine or some other spirit, in which condition it can be readily filtered through charcoal. The spirit is then distilled off in an air-tight apparatus, leaving the white paraffin behind. Preparations are being made, I am told, for carrying this out on a large scale. The process with which I am acquainted, and by which the ozokerit candles are produced, consists in distilling the crude mineral in a current of superheated steam, the apparatus employed being very similar to that used in distilling palm oil. I have on the platform the original experimental plant in which our first experiments were made. You notice the series of vertical tubes, each lower bend of which is furnished with a cock, from which the condensed distillate runs. The lighter vapours are caught in this so-called "essence tank," where they are met by a jet of water, which carries them down with it. By this means, we obtain nearly 70 per cent. of a beautiful white paraffin, melting at 142° F. Of course, as it comes from the still, the ozokerit has not this appearance; it is a dirty grey, and is subjected to a series of treatments, similar to those undergone by paraffin wax, and already described. A very ingenious process for removing the oil from the paraffin without pressing has been patented by Mr. Sterry. It consists in simply washing the wax with soap and water. I have here a model of the apparatus employed. The impure paraffin is filled into bags, which are strapped on the larger of these two revolving cylinders of framework, and the trough being filled with a weak solution of alkaline soap, at a temperature of some 10° below the melting point of the paraffin, the big cylinder is revolved pressing firmly against the tooth-like ridges in the smaller. By this means the scale is thoroughly kneaded, and the oil to a great measure extracted, under the gracious influence of the warm alkali. The paraffin thus obtained is of a pure white, but opaque, which renders it useful for a certain class of candles only. A great agent in purifying the products of distillation is fullers' earth, which is capable of rendering the most refractory substances white and transparent.

Looking back now on all the materials which the animal, vegetable, and mineral worlds afford to the candle-maker, we have tallow, wax, sperm, palmitin, stearin, and paraffin. Tallow and wax candles have been separately described, as their mode of manufacture differs from the others, or mould candles. These were, until the commercial strain produced by Young's and Chevreul's discoveries had made itself strongly perceptible, made in hand-moulds—a comparatively slow and laborious process. I have here one of the old hand-frames, which are not yet quite out of date, inasmuch as some people, for reasons best known to themselves, insist upon having their candles made in this manner; and also because there are certain sizes which are not in sufficient demand to justify making separate machines for them. As you see, the hand-frame consists of about two dozen moulds, held together by wood-work, opening into a trough at the top, the points being downwards. The wicks have to be carefully cut to size, and each one provided with a little cotton loop; a long piece of wire armed with a crotchet-hook at the end is passed out through the tip of the mould, and catches the little loop aforesaid, which is then pulled up to the base, and a short piece of wire passed through it, which is kept in position by two little notches in the upper rim of the mould. The wick is then pulled tight by the end emerging from the top and secured by a little wooden peg. When all the moulds are thus furnished, the frame is ready for filling. This is accomplished by the pouring in of the material until the trough itself is quite full, thus allowing for the contraction of the liquid in the pipe which takes place on cooling, and is very considerable. The frame is then placed in water, the temperature of which is regulated according to the nature of the material—paraffin for instance, requiring as cool a water as possible, sperm and stearine, tepid. When cooled, the superfluous material is removed from the trough by a sharp-edged trowel, and the candles extracted from the moulds by tapping the points with a mallet. The hand-made candle is readily distinguished by the little groove which the wire wick-holder makes in the base.

I am unable to say precisely when the candle machine was invented; as far as I can learn, it was introduced into this country from America, about 1848–50. Mr. E. Cowles, of Hounslow, made several improvements therein, and brought it to its present state. He has been good enough to lend me these working models, which will assist my description. From 80 to 100 moulds are enclosed in the casting box, which moulds are open at each end. The tip which forms the top of the candle is fastened to a tube of iron, through which the wick passes. These tubes are fastened to a platform, moved up and down by a rack and pinion. The wicks are wound on bobbins, enclosed in the case below. The candles, being filled into the moulds, are cooled by water surrounding the pipes, the temperature of which can be regulated by the admission of steam, through pipes at the side. When hard, the crank is turned, which works the rack and pinion, and pushes up the tips, with tubes attached. These carry up the candles, which, on emerging, are grasped by an apparatus called a nipper, made of wood, lined with indiarubber. When the candles are fully withdrawn, and held in position by the nipper, the platform with wick pipes and tips is lowered to its normal position, thus closing the ends of the moulds, and these are again filled. As soon as the superficial cake has solidified sufficiently to ensure the steadiness of the wick, the candles above, which have hitherto acted as wick-holders, are cut loose, and removed in the nipper. Thus twenty or thirty batches can be made from one set of wicks.

A great improvement in the candle was made in 1861, when Mr. J. Lyon Field patented the conical "butt," by which a candle could be adapted to any candlestick, without paper or scraping. This invention naturally demanded a different machine for carrying out its purport, as, the butt being taper, and larger at the point of junction with the candle than the diameter of the same, it would have been impossible to extract it from an ordinary mould. The moulds for the butts are cast in a separate frame, which is removed, when the candles are finished, by a chain and pulley, and the candles then pushed out of the stem moulds in the ordinary manner. The idea is not mechanical, and several other neater methods have lately been patented, with varying success.

The temperature at which the candles are poured, and the time allowed for cooling, requires much care and experience to determine. When stearine candles were first introduced, their tendency to crystallize was so great, that it militated against their introduction. Various ways of remedying this defect were resorted to—actually *arsenic* being employed—until the simple expedient of allowing the melted material to cool in the pan, under constant stirring, till close on the point of solidifying, and then pouring into warm moulds, entirely put a stop to the nuisance. The wicks also of the candles are an endless source of care. Every description and size of candle has its particular wick, of so many plaits, and so many threads. The wicks, again, have to be soaked in various preparations, accordingly as they are for wax, sperm, or stearine. Upon the ornamentation of candles, too, endless knowledge and skill has been expended. These wax candles, about fifty years old, heavy with vermilion and ultramarine, and

"With uncouth sculpture decked."

compare poorly with the exquisite forms and tints of the myriad lights on this table. The introduction of aniline colours into paraffin is a pretty discovery. You will see that, when I add a little magenta base to to this beaker of paraffin, the liquid is not coloured at all. I now dissolve the dye in stearine, forming stearate of magenta, and a drop of this, added to the paraffin, dyes it of a gorgeous pink.

We have here candles cut and carved into every grotesque and beautiful shape—the spiral, the cable, the King Alfred, and the fluted—also a great variety of inventions, based on the even burning of a candle in a case, forced up by a spring. This horological candle, for instance, where the spirally ascending spring revolves a clock-glass, illuminated by the candle within. These dumpy little candles are the so-called "moons," which are employed in spring lamps for carriages and signals. Then there are many pretty ideas for preventing guttering, and supplying a shade which shall descend with the candle, all of which are explained better by examination than description.

I must confess, though, that, to my taste, nothing is to be compared, for elegance, with a plain, white, transparent candle. Stearine candles are undoubtedly the best for work, as they never bend or gutter; but the dead white is not pleasant, and the light is not equal in brilliancy to that of paraffin. Sperm candles are also very beautiful, and it is rather surprising that they are not more used; the price, perhaps, has much to do with this. The great objection to paraffin candles is their liability to gutter, if of low melting point, and further, to bend. This plasticity of paraffin is a very curious phenomenon, as it does not seem to be affected by the melting point, except in the time taken to acquire it. Ozokerit-paraffin is of so high a melting point, that the candle is consumed, generally, before the bending point is reached. Here you will observe various paraffin candles, which have been kept in a steam cupboard, at a temperature of about 100°, for an hour. The melting points vary from 115° to 140°; the latter being ozokerit. All, you see, have bent, that of 115° nearly double, but the ozokerit has not even a slight curvature. This valuable property arises, no doubt, from the homogeneity of the earth-paraffin, while all others are mixtures of higher and lower homologues. The light of an ozokerit candle is as 10 : 7·5 of sperm, 7 of wax, 7·25 of stearic acid, and 3·5 tallow. But there can be no question that no paraffin candle, as yet, gives the amount of light which it should by theory, and which it would do were its substance vaporized in a lamp. The cost of a candle will always transcend that of other forms of luminants, but its convenience and safety, on the other hand, more than compensate for this inequality, where comfort is allowed to enter into consideration of economy. The still, the supply pipe, the burner, all are condensed into one little apparatus, and remain equidistant, and the supply equable to the demand, till the end. This it is, combined with the purity of the combustion products, that has secured the candle its popularity, and will continue to do so as long as lights are burnt by man.

Gas and electric lighting have taken high rank as sciences, and justly so, involving, as they do, such profound thought and supreme skill. But the candle and the lamp have also called forth the highest powers of great scientists to perfect them,—Chevreul and Young laboured for little else,—and they are now nearly perfect of their kind. So, while honouring to the full the authors of the greater lights, we must not forget the many workers whose labours have brought the candle from the crude, smoky wax and tallow, to the beautiful form and light it now owns, of whom more than six generations sleep in the shadow of old Lambeth church, with no other monument than that of a fair life and faithful toil.

To those of the craft, and others, who have so kindly and courteously assisted me with their knowledge and specimens, I here tender my hearty thanks.

Parliamentary and Law Proceedings.

Prosecutions of Chemists under the Sale of Food and Drugs Act.

At the Marylebone Police Court, on Tuesday, Mr. Alfred W. Pipe, chemist, of 1, King's College Road, St. John's Wood, appeared before Mr. Mansfield to answer two summonses taken out at the instance of Mr. George Smith, inspector of nuisances for the parish of Hampstead, for selling to him, on June 14, 6 ounces of "spirit of nitrous ether, B.P.," not of the quality of the article demanded, inasmuch as it did not contain the proper quantity of nitrous ether, namely, 2 per cent.

Mr. Ricketts, solicitor, appeared in support of the summonses; and Mr. Glaisyer, solicitor, defended on behalf of the Chemists and Druggists' Trade Association of Great Britain.

Mr. G. A. Smith deposed that on June 14 he applied in defendant's shop for 6 ounces of spirit of nitrous ether, B.P. He informed the defendant's assistant, who served him, that he intended to submit it to analysis, and offered to divide the sample, but the vendor said he did not want a portion. The assistant said he believed the sample was all right, and Mr. Pipe observed that he could not guarantee it to be "B.P.," but he had no intention to defraud the public. Witness took the spirit to Mr. Heisch, the public analyst of the parish.

In cross-examination the witness said he removed the label from the bottle supplied to him by the defendant, as the Act required that the analyst should not know from whom the sample had been taken. He would not swear that the bottle was not marked "sweet spirits of nitre." He handed a written order to Mr. Pipe. After being served he heard the defendant and his assistant in conversation. They said something about there being a "London Pharmacopœia" as well as a "British Pharmacopœia," and that the two authorities differed as to the constituent parts of certain preparations. Mr. Pipe also said that he kept preparations according to both standards, and that he could not guarantee what he sold to the witness to be "B.P.," as there had been some misunderstanding on the part of his assistant with regard to the bottles, but that was after the purchase was completed. He purchased at the same time 2 ounces of citrate of iron and quinine and 3 ounces of tincture of quinine; there was no charge against the defendant in respect to those articles.

Mr. Charles Heisch, analyst, said the quantity of nitrous ether in the sample submitted to him was so minute that if he had followed strictly the directions contained in the British Pharmacopœia he should have said it contained none at all. The more delicate method of testing adopted by Dr. Dupré, however, showed that it contained ·69 instead of 2 per cent. The specific gravity was ·8477 instead of ·845. It was not "spirits of nitrous ether, B.P."

In cross-examination witness said he knew the London Pharmacopœia article, and he should suppose that there would be no more profit in selling one than the other. He admitted, on looking at the last reprint of the B.P., handed to him, that the original words, "2 per cent. of nitrous ether," were altered to "2 per cent. of an ethereal liquid," and that the ethereal liquid might contain aldehyd.

Mr. Glaisyer, in defence, said his client kept both the preparations referred to. The assistant had used the wrong bottle. Furthermore, the bottle given to Mr. Smith was labelled "sweet spirits of nitre," and not "nitrous ether."

The Magistrate said he did not think the case was one to be dealt with under the Act. These proceedings would doubtless act as a caution to the defendant in the future. It appeared to him to have been an accident by which one article was sold for another without any extra profit to the vendor. There was also some uncertainty as to whether the conversation with respect to the nature of the preparation took place before or after the completion of the purchase and as to the amount of nitrous ether required. Under all the circumstances, he felt himself justified in dismissing the summons.

The Magistrate then proceeded to hear a summons against Mrs. Jane Allchin, of 1a, Elizabeth Terrace, Hampstead, who was also summoned by Mr. Smith for selling 6 ounces of spirit of nitrous ether, not containing the necessary quantity of nitrous ether, namely, 2 per cent. She was further summoned for selling 3 ounces of tincture of quinine not containing the proper quantity of sulphate of quinine, namely, 8 grains to 1 ounce.

In the first case it was admitted that sweet spirit of nitre, P.L., had been supplied for spirit of nitrous ether, B.P., and Mr. Mansfield imposed a nominal penalty of 5*s.* and 2*s.* costs.

With respect to the second snmmons, the purchase having been proved,—

Mr. Heisch said he had examined the sample of tincture of quinine and found it to contain 6·2 grains of quinine sulphate to the ounce, whereas it should contain 8 grains to the ounce. He had never known the quinine to crystallize out in cold weather. His process of analysis was to evaporate, treat with dilute sulphuric acid, add ammonia, wash the precipitate with water, dry and weigh.

For the defence, Mr. E. C. J. Davis said he had acted as an assistant to the late Mr. Allchin and Mrs. Allchin for the last five years. He made the tincture in question strictly in accordance with the British Pharmacopœia, putting 320 grains of quinine sulphate (Howard's) into 2 pints of tincture of orange; that would be 8 grains per ounce.

Professor Attfield, F.R.S., said a third portion of the divided sample had been submitted to him for analysis, and he had found quinine present equal to about $7\frac{1}{2}$ grains (7·4 grains) of sulphate per ounce. By the process a little quinine would be lost. In his opinion Mr. Heisch's method of analysis was untrustworthy. Chloroform and ether should have been employed.

The opinions of the two chemists being at variance, the summons was adjourned for fourteen days in order that a sample of the preparation might be submitted to the analysts at Somerset House.

Mr. Joseph W. Allen, of 19, Elizabeth Terrace, Hampstead, also appeared in answer to two summonses for offences under the provisions of the Act.

The first was for having sold tincture of quinine which contained only 5·66 grains to an ounce instead of 8 grains. Evidence having been given in support of the summons, Mr. Glaisyer said that unfortunately the defendant was foolish enough to refuse to take the sample which the inspector offered him, so that in respect to this and the next summons the Association he represented had no data to go upon. He was, however, instructed that the nitrous spirit was prepared according to the London Pharmacopœia, and the quinine according to the British Pharmacopœia.

Mr. Allen said he had made the tincture himself, and put the quinine sulphate in at the rate of 8 grains per ounce. Some of the quinine might have become deposited at the bottom of the stock bottle.

The Magistrate imposed a penalty of 5*s.* and 20*s.* costs.

The second summons was for supplying, when spirit of nitrous ether, B.P., was demanded, a preparation of sp. gr. ·8475, and containing ·649 nitrous ether.

Mr. Allen said he sold the preparation as he received it from a wholesale house.

Penalty of 5*s.* and 2*s.* costs.

Poisoning by Laudanum.

On Monday, Mr. S. F. Langham held an inquiry, touching the death of Mr. Augustus Lang, residing in Cambridge Street, Pimlico.

A servant stated that on the previous Tuesday night deceased went to bed earlier than usual, and at 9 o'clock he called her up, and requested her to fetch sixpennyworth of laudanum. Deceased said he wanted to take a few drops with some brandy to procure sleep. She left him with the brandy on the table, and sent a man for the laudanum. Next morning on going to his room she could obtain no answer, and, on assistance being procured, deceased was found dead in bed.

Dr. Cass, of St. George's Road, Pimlico, said that when called in on Wednesday morning the deceased had been dead some hours. The *post-mortem* examination showed that the liver weighed 100 ounces—more than twice the normal weight. The organs were much congested, but there was no smell of opium in the stomach. No doubt death was due to an overdose of opium. The bottle found near the bedside contained six teaspoonfuls of laudanum, and over four were gone. The poison should not have been supplied except on a medical certificate.

The Coroner was about summing up to the jury, when the brother of the deceased protested against the termination of the inquiry without the examination of the chemist who sold the laudanum.

The Coroner's officer said the chemist was out of town, and declined to attend; he stated that he had sold as much as a pint at a time, and in this case, as in others, he cautioned the purchaser of the poisonous properties of the drug, and properly labelled it.

The Jury returned a verdict of "Death from an overdose of laudanum, taken accidentally."—*Times.*

The Hop Gardens, and B.P. Hops.

Sir,—Your correspondent A. S. (from Milton, Kent) last week described what is at this season of the year a very interesting and pretty sight, a visit to the hop gardens during the "hopping time," and to the drying kiln. These I have often visited in Sussex, but in this district, when I was last there (September 4), hop picking had not commenced. It is evident A. S.'s letter was written previous to the hop grower's "black Sunday," September 2, the storm of which did immense damage to the growing hops, in all but the most sheltered gardens. One farmer lamented at Rye next day that it had blown £1000 out of his pocket. Not only were the leaves on the vine battered and blighted by it, but the bracts of the strobile itself were bruised and shrivelled, as I saw them on the Tuesday, in such a manner as to make it evident they would not produce a presentable sample; at least, this was the case with all those exposed to the south, however much protected by high hawthorn hedges, etc. Still, I learn later they have not suffered much in some gardens, but the hop grower—the British farmer intensified for grumbling—grumbles in the hopes of producing advanced prices. The hop is a delicate plant, and a very precarious crop; its cultivation in Kent and Sussex is carried on with the greatest care. This is specially the case in regard to the mode they have of protecting them as much as possible from exposure to winds. A fortnight ago I passed through a large hop growing district in Bavaria, between Nuremberg and Aschaffenburg, but not where the best Bavarian hops are grown, I was told. Here I noticed the plants were grown quite in the open, like other crops, there being no division of land into fields by hedgerows, such as we have in England, and no attempts were made to shelter the hops even; as a rule too the poles were much higher than the Kentish, which made the plant more exposed. The crop was not considered a good one there. The leaves on the lower part of the vine had turned quite yellow, yet no harvesting had commenced that I saw. The plants too, having in many cases "topped the tall poles," had a spindly appearance as compared with the luxuriousness of the Kentish crops prior to the 2nd inst. Your correspondent mentions the fires made of coke and sulphur used to dry the hops in the Kentish kilns and a strong odour of SO_2 which affected him in the drying room, without stating for what purpose it is used. The sulphurous anhydride is generated for the purpose of bleaching the leafy bracts of the strobile, which otherwise would be of a dull brown colour if dried without this bleaching; it is, in my opinion, a mistaken idea, but it makes the bleached pocket of hops much more marketable, I am told.

The official hop in the British Pharmacopœia is stated to be "the dried strobile of the female plant of *Humulus Lupulus*, Linn."—not the sulphured hops of commerce (?). Are we any more justified in using bleached hops in making preparations of them than we should be in using bleached ginger? A scrupulously conscientious pharmacist of my acquaintance dries his own hops without sulphuring them to use for making his preparations. I have prepared a tincture of the fresh strobiles, equal in strength to B.P., by using a spirit equal in strength to proof spirit, and estimating the loss, ascertained by drying a sample, as water. Compared with the tincture of the sulphur-dried hops, I find it slightly more alcoholic and paler in colour; diluted with water it makes a more opaque milky mixture, has much more aroma, as well as more of the bitterness of the hop, but it is minus a part of the flavour of the tincture of the dried hop. Both the tinctures have a slightly acid reaction, the fresh apparently not less than the dried, which I expected would be the case, through the latter retaining some of the acidity from the sulphur, probably as sulphuric acid. In the London Pharmacopœia, "*Lupulus.—Humulus Lupulus*, Amentum," was ordered, not necessarily dried, and therefore it might be construed that the converse—fresh—hops were intended, but I suppose never used. It is curious, that as the citizens of London petitioned against the use of hops, "in regard they would spoyl the taste of drink, and endanger the people," whence Henry VIII. issued an injunction "not to put any hops or brimstone into the ale," that these two substances should have such a preservative action on ale in the way of preventing it, to a considerable extent, undergoing acetous fermentation. A trace of sulphur is sublimed into the hops, and probably remains as such till it is used in the beer. Hence it may be essential for brewery purposes that the hops should be sulphured. Englishmen are probably too much accustomed to the use of hops in beer to derive much benefit from them medicinally, much as they may be vaunted by advertisement. Still they have mild tonic and stomachic, as well as slight narcotic properties, mostly residing in the lupulinic glands.

10, *New Cavendish Street, W.* Wm. Martindale.

The Duties and Responsibilities of the Chemist in Cases of Accidental Poisoning.

Sir,—I have read with some interest the letter of your correspondent, "Mors'," in last week's Journal, on the above subject, and shall be glad if you will allow me to venture my opinion thereon.

The case he alludes to is one quite different to an ordinary one of petty ailments which a chemist is often called upon to prescribe for, and under the circumstances I think he acted quite right, and was quite within his province in administering the antidotes. I should certainly have gone with the woman and made sure that they were administered. I do not advocate that chemists should be permitted to visit patients or even prescribe for serious ailments; but cases of poisoning should not allow of any hesitation on the part of the chemist, in the absence of a medical man, using his utmost skill and all the knowledge he possesses in placing the person out of danger, and should he fail to do so he will have the satisfaction of knowing that he did his best.

Stoke Ferry. W. H. Newsam.

R. Brown.—Your advertisement, with enclosure, has been forwarded to the publishers, Messrs. J. and A. Churchill, 11, New Burlington Street, to whom all advertisements should be sent.

R. H. R.—We are unacquainted with any such work.

Inquirens.—(1) The preparation mentioned is a proprietary article, the formula for which has not been published. (2) You do not mention your difficulty. Probably you will find the information you require among the Dispensing Memoranda which appeared in vols. x., xi. and xii. of this Journal.

Spondalium.—Formulæ for syrup of lactophosphate of iron and lime will be found in vol. iv., p. 610, and vol. vi., p. 882, of the present series of this Journal.

X. Y. Z.—The cause of the explosion is very obscure. We are making inquiries upon the subject, and should anything explanatory be learned it shall be communicated to you.

X. Y. O.—(1) *Senecio Jacobæa.* (2) *Reseda lutea.* (3) *Lathyrus pratensis.* (4) *Veronica Beccabunga.* (5) *Ranunculus hederaceus.* (6) Probably *Silene inflata*; send a specimen in flower.

T. P. J.—The name is not included in the Register of Veterinary Surgeons published at the commencement of the present year.

Apprentice.—(1) Probably *Rumex crispus*: leaves should be sent. (2) *Sisymbrium officinale.* (3) *Carduus palustris.* (4) *Senecio Jacobæa*, probably: leaves should be sent. (5) *Geranium sylvaticum.* (6) *Achillea Ptarmica.* (7) *Calluna vulgaris.* (8) *Pedicularis sylvatica.*

J. Kemble.—Thanks. The occurrence is not common, the modification usually taking place in the filaments. A similar change takes place in the columbine.

Apprentice.—If you look through the advertising pages of this Journal, you will find the information you require.

H. J. Thomas.—Tincture of gelsemium is now official in the United States Pharmacopœia. It is made by percolating gelsemium in No. 60 powder, 15 parts, with sufficient alcohol, sp. gr. 0·820, to make 100 parts of tincture.

Communications, Letters, etc., have been received from Messrs. Benger, Cassian, Brook, Lincoln, Associate, Asparagus, Morti, R. H. R.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 22, 1883.

THE BRITISH PHARMACEUTICAL CONFERENCE AT SOUTHPORT.

THE meeting of the British Pharmaceutical Conference, which commenced in Southport, on Tuesday morning last, will be memorable in the history of that Association for the large attendance and for the admirably conceived address of the President, Professor ATTFIELD, F.R.S. This address is printed *in extenso* in another part of this Journal, and since it will no doubt be perused with interest by the majority of those into whose hands it will thus fall, it needs no lengthened analysis or even commentary in these columns; but as it has already been criticized by the general public press from points of view different to that taken by Professor ATTFIELD, we have reprinted some of the articles that have appeared on the subject in the daily papers for the purpose of enabling our readers to become acquainted with the views entertained outside their own circle. The address, it will be seen, deals with the relation of the State to pharmacy, and forms a fitting continuation of the address of last year in which Professor ATTFIELD discussed the relation of pharmacy to the State. On the present occasion the speaker, starting with the proposition that Parliament intended by its legislation in the year 1868 to "provide for the proper supply of trustworthy drugs to the public," and to ensure that no person should act towards the public as a chemist and druggist unless he had satisfied State examiners that he was properly qualified and had his name enrolled on a State register, proceeded to discuss the various ways in which this intention of the Legislature has been thwarted and the unfortunate consequences to the public and pharmacists. It must be admitted that the picture drawn of the present condition and future prospects (if there be any) of the large majority of pharmacists in Great Britain will appear to many a sombre one, but the characteristic energy of Professor ATTFIELD had placed within his reach a mass of evidence which he used with effect in support of his position. The remedy for the evil which commends itself to Professor ATTFIELD'S judgment is, in accordance with views expressed last year, the extension of the letter and spirit of the existing Pharmacy Act, so that not only the dealing in a few virulent poisons, but the "retail sale in open shops of most of the simple and "compound medicines of the British Pharmaco-"pœia" should be carried on only by qualified druggists. That these views found favour with his audience is not surprising, and it may be hoped that the steps which are to be taken to bring them under the notice of members of both Houses of Parliament will be productive of good results. Meanwhile it is a good omen that some of the leading organs of public opinion have practically endorsed more or less the claim for consideration of their grievances put forward by Professor ATTFIELD on behalf of the pharmacists of Great Britain.

With respect to the position of the Conference it is satisfactory to find from the report presented by the Executive Committee that it continues to enjoy a fair share of prosperity. The special effort made to bring the Association under the notice of chemists and druggists who had not already joined it is stated to have already resulted in a considerable accession of members, whilst the Treasurer was able to report that the income had been more than sufficient to cover the expenditure.

At the conclusion of the address the Conference was adjourned for luncheon, which was provided by the liberality of the Local Committee in an adjoining room, after which many members took the opportunity of visiting the Aquarium and Winter Garden.

In the afternoon the reading of papers was commenced and according to the usual custom the reports upon subjects for the investigation of which money had been granted from the Conference funds were taken first, priority among these being given to a second report by Mr. A. H. JACKSON on "The Differences between the Essential Oils of Cinnamon and Cassia." In his previous report Mr. JACKSON dealt chiefly with the physical behaviour of the two oils and stated his opinion that, whilst there was some difference in their specific gravity and refractive energy, there was nothing sufficiently characteristic to supply a satisfactory method of distinguishing between them. In the present report more particular attention is paid to the chemical aspect of the question. The most promising experiment consisted in a comparison of the behaviour of the residues of the two oils after the removal of all the cinnamaldehyde by treatment with potassium bisulphite and ether; but although some slight differences have been noted they are not sufficiently definite to encourage further work in that direction.

The next report was on the "Bitter Principles of *Nerium odorum*," by Mr. H. G. GREENISH, who described two substances, one crystalline and the other amorphous, and both freely soluble in spirit, separated from a solution obtained by shaking an aqueous percolate of the powdered root with chloroform until all the bitterness had been removed. The exact nature of these two substances will form the subject of a future report. In passing a vote of thanks to the reporter the opportunity was taken to pay a well-deserved compliment to Professor DYMOCK, who supplied the crude drug operated upon, and who is continually contributing in one way or another to the elucidation of the history of Indian drugs.

The "Quantitative Separation of Strychnine and Brucine" formed the subject of the third report, which was by Messrs. DUNSTAN and SHORT, and in the words of the President constitutes a distinct advance in knowledge respecting these alkaloids.

The process devised by the authors for the separation of the two alkaloids is based upon the difference in the solubility of the ferrocyanides of strychnine and brucine, produced by the double decomposition of the alkaloidal sulphates and potassium ferrocyanide. Strychnine ferrocyanide is but very slightly soluble in water, whilst brucine is much more soluble; but it has been found that in neutral solution a larger quantity of the strychnine salt remains in solution if the brucine salt be present, and in alkaline solutions the separation is not so complete as is desirable. If, however, the solution of the sulphates be acidified with sulphuric acid, the strychnine is entirely precipitated by potassium ferrocyanide, both alone and in the presence of brucine, the brucine not being precipitated under similar conditions until the strength of the solution approaches saturation and then slowly and in large silky needles, differing from the granular and heavy precipitate of the strychnine salt. In another report, upon the "Tincture of Nux-Vomica," the authors stated that, as might be expected, the difference in alkaloidal strength which in a former paper they showed to exist in the nux vomica seeds of commerce is perpetuated in the galenical preparation. They gave the results obtained in the analysis of twelve specimens of tincture of nux vomica obtained from different sources, from which it appears that whilst the strongest tincture contained 0·360 per cent. of total alkaloid, of which one-third was strychnine and the remainder brucine, the weakest only contained 0·124 per cent., or just over one-third as much total alkaloid. The relative proportion between the two alkaloids was tolerably constant throughout the series of specimens, with the exception of one, in which they were present in equal quantity. These variations in the alkaloidal strength of tincture of nux-vomica confirm the conclusions arrived at some years since by Mr. Siebold, based on the relative bitterness of dilutions of some specimens, and point to the necessity for in some way standardizing the strength of this powerful preparation, if not to the advisability of abandoning it as far as possible in favour of the liquor strychniæ. Such a course would be affected, necessarily, by a knowledge of the physiological behaviour of brucine free from strychnine, and the process of the authors for separating the two alkaloids appears to furnish a favourable opportunity for clearing up this point.

After the reports had been disposed of, the first paper read was on the "Preservation of Medicinal Herbs by Ensilage," by Professor Quinlan, and described the results of some experiments in which medicinal herbs were submitted to treatment analogous to that followed in the process of ensilage of green fodder. The herbs in a fresh state were bruised to a pulp in a mortar, and the pulp packed closely into glass bottles, leaving only room for the stoppers, which were covered with beeswax, the bottles being afterwards buried in the earth. After treatment in this way belladonna, conium, and other herbs were found to be "perfectly sweet and fit for pharmaceutical use" at the end of four months. It is evident, however, that although herbs so preserved may be still "fit for pharmaceutical" use it does not necessarily follow that they will exactly represent the "live plant," upon the relative superiority of which Dr. Quinlan enlarged, since if the process is really equivalent to ensilage the vegetable substance will undergo a certain amount of fermentation, probably lactic, which might affect the active principle, whilst, as pertinently remarked by Mr. Stanford, the product would no more represent the fresh herb than sour kraut does the fresh cabbage. However, the subject is of considerable interest, and pharmacists are indebted to Dr. Quinlan for directing attention to it and for his promise to continue his experiments under varying conditions that were suggested in the course of the discussion.

The next paper read was by the same author and dealt with the Medicinal Properties of the Mullein Plant, which he described as being useful in the early stages of pulmonary consumption in a manner similar to cod liver oil or Russian koumiss. The particular mullein to which he referred, the *Verbascum Thapsus* of botanists, is frequently spoken of by ancient Irish medical writers and has long been used in Ireland for the relief of phthisical patients. The preparation specially recommended is a decoction of the fresh leaves in milk, either in its natural state or previously peptonized. So great is the demand for this plant that it is cultivated in several parts of Ireland, and it would be interesting to ascertain the exact effect of cultivation upon it. The sample of the fresh plant shown by Dr. Quinlan, was said to be the kind used, although a "poor specimen;" but it differed so much in the colour, texture and shape of the leaf from the characters usually observed in the *Verbascum Thapsus* plant as met with wild in this country that it might have been taken for another species. It may be useful to point out that the resemblance between the leaves of young mullein plants and those of young foxglove plants calls for the exercise of discrimination.

With this paper the business proceedings of the Conference on Tuesday terminated, and the majority of the members went to witness a display of swimming in the Victoria Baths, which by the courtesy of the directors was thrown open to them.

On Wednesday morning the proceedings were resumed with the reading of some "Additional Notes on the Bitter Principle of *Hymenodictyon excelsum*," by Mr. W. A. H. Naylor. It will be remembered that in a paper read a short time since at an Evening Meeting of the Pharmaceutical Society, the author gave some preliminary information respecting a bitter alkaloidal substance that he had isolated from the bark of this Cinchonaceous plant and which he then thought to be closely allied to, if not identical with paricine. Further investigation has proved it to be a new alkaloid having a composition corresponding to the empirical formula $C_{24}H_{40}N_3$, and therefore an addition to the small class of bases devoid of oxygen. Besides "hymenodictyonine," which is the name given to the new alkaloid, Mr. NAYLOR has separated a bitter neutral principle, represented by the formula $C_{22}H_{43}O_{10}$, which he thinks may possibly be a decomposition product of a glucoside.

The next paper was a very practical one by Mr. WILLMOTT, entitled "Remarks on Experiments with the Ointment Bases," which in consequence of its great length was summarized by the author. The object of the experiments was to contribute towards clearing up the pharmaceutical side of the question as to what is the best substance to be used as a basis for ointments in respect to securing efficiency and stability, the substances experimented upon being lard, oil and wax, and mineral hydrocarbons, and the experiments having been continued over a considerable period. It will be impossible to convey any adequate idea as to the nature of this paper without the publication of the instructive tables by which it is accompanied, and the conclusions arrived at can only be mentioned here in the briefest manner. The author infers from the results of his experiments that the washing and straining, or washing and filtering, of lard are without advantage in its preparation for use as an ointment basis, the best results having followed the simple process of melting and straining. In any case the coudition of rancidity in lard is quickly developed, though it may be obviated to a very large extent by the use of benzoin. Mixtures of oil and wax are stable when the yellow unbleached wax is used, but not when the official "white wax" is used. Of the various hydrocarbons hitherto in use as ointment bases, the author is inclined to award the palm to vaseline, but he says that he has found it to develop a disagreeable odour, especially when melted with paraffin, "white wax" or spermaceti, or in the presence of carbonate or acetate of lead, but the odour is not developed when yellow wax is mixed with it. Another new hydrocarbon basis, called "white ozokerine," was reported to have given more satisfactory results.

Mr. SIEBOLD then read a note on the "Processes of the British and United States Pharmacopœia for the Determination of Hydrocyanic Acid," in which he stated that subject to the correction as to the volume of silver nitrate solution required to indicate a certain strength, first pointed out as necessary by Mr. CRIPPS, and if precautions be taken for the absence of chlorides from the magnesia and hydrochloric acid from the hydrocyanic acid, the U.S.P. process is as reliable and delicate as that of the B.P. In the discussion a preference for the B.P. process was expressed by Mr. J. WILLIAMS on the ground that hydrochloric acid is almost invariably added to hydrocyanic acid as a preservative, and Mr. SIEBOLD pointed out that where it was desired to repeat the determination one process might be conveniently used to check the other.

In a paper on "Iodine in Cod Liver Oil," Mr. E. C. C. STANFORD described the results of experiments made with the object of testing the statement attributed to GARROD that "cod liver oil" contains 0·06 per cent. The author says that if this statement were true, cod liver oil would be the richest source of iodine with which we are acquainted; but although he found iodine present in every specimen examined, it never exceeded 0·000434 per cent., the mean of six specimens being 0·000322 per cent. More than double this mean quantity (0·000517 per cent.) of iodine was found in fresh cod liver, and the metalloid was also ascertained to be present in the flesh of the cod and the Scotch herring, in herring brine and in fulmar oil. It may be remarked that this "statement that cod liver oil contains 0·06 per cent. of iodine," which in the "blue list" and by various writers has been repeatedly referred to GARROD, does not correctly describe what is said by that author, whose words are: "the proportion of iodine is *not more* than 0·05 per cent."

The time having nearly arrived for the adjournment to luncheon, Mr. HOLMES briefly communicated some information respecting the trees yielding benzoin, and exhibited specimens of the leaves and sections of the trunk of the Siam benzoin tree, and leaves, flowers and fruit of the Sumatra benzoin tree, which have recently been received from Mr. JAMIE, of Singapore.

Upon resuming, the next two papers read were by Mr. CONROY and Mr. MABEN and discussed the Suitability of Sesame Oil for Pharmaceutical Purposes. Mr. CONROY is of opinion that sesame oil cannot replace olive oil for the chief pharmaceutical uses, since from the large proportion of olein it contains plasters made with it do not "set," whilst lime liniment made with it shows a tendency to separate. But in preparations where no chemical combination takes place, and where only a bland sweet oil possessing good keeping properties is required, perhaps no better could be chosen, and he thinks it might serve as a substitute for almond oil in the preparation of ointments. Mr. MABEN's opinion of sesame oil is somewhat more favourable, since he thinks that it might not only take the place of olive or almond oil in the preparation of ointments,—except ung. hydrarg. nit.,—but that it could be made applicable to plasters by a modification of the proportions of the ingredients.

In a note on "The State of Combination in which Morphia exists in Opium," Mr. D. B. DOTT gave his reasons for believing that morphia exists in opium both as sulphate and meconate. Although sulphuric acid is present in opium in sufficient quantity to combine with the whole of the morphia, there are also other bases present with which it will unite in preference, and the residue of the acid is not sufficient to satisfy the whole of the alkaloid. On the other hand, meconic acid is not present in sufficient quantity to take up all the alkaloid, and probably forms an acid salt with the portion with which it does combine.

The apparently interminable subject of Sweet Spirit of Nitre formed the topic of a paper by Mr. A. C. Abraham. This gentleman has been led to the conviction that the generally received explanation of the official process for spirit of nitrous ether is erroneous and to impute the moderate action and constant temperature peculiar to that process rather to the action of the sulphuric acid upon nitrate of copper, or to the increase of the boiling point by the admixture of sulphuric acid, than to the formation of nitrous acid. After some experiments in which the copper was first converted into nitrate, the author eventually abandoned this for calcium nitrate and he gave a formula for a process which he says presents the advantages over the official one of giving a greater yield at a smaller cost, with a less prolonged, more regular distillation and a smaller quantity to be distilled, whilst the action which takes place is more analogous to that in the older processes. In the course of the discussion Mr. J. Williams made some suggestive observations as to the possible composition of this preparation. He said that he had prepared ten per cent. solutions of pure nitrous ether and of aldehyd, but that neither resembled "spirit of nitrous ether," and the same remark was true of a mixture of the two; but a solution of paraldehyd sufficiently resembled it to raise the question whether the aldehyd was not present in the preparation in this condensed form, its action being perhaps modified by that of nitrous ether.

The results of an Examination of some Samples of Pitch were then communicated by Mr. E. Davies, with a table of their composition, from which it appeared that the organic matter dissolved by petroleum spirit from samples of Trinidad and Syrian pitch contained 5 or 6 per cent. of sulphur, a much higher proportion than exists in any known vegetable substance. The President took the opportunity of pointing out that the asphalt used for paving purposes contains more than 90 per cent. of inorganic matter and is incombustible.

A "Contribution to the Pharmacy of the Pomegranate," was next read by Mr. L. Siebold, in which a preparation was described which consists essentially of a solution in syrup of orange peel of an extract made from an aqueous infusion of the powdered root bark of *Punica granatum*, which has been deprived of all astringent matter by treatment with sugar of lead. It is said to have a pleasant fruity flavour, and be very effective.

The subject of the next paper, which was by Mr. Conroy, was a sample of spurious scammony, which appeared to consist of "skillip" scammony and upwards of 83 per cent. of the resin from the root.

In a paper on "Aconitine for Internal Administration," Mr. T. B. Groves refers to the small extent to which medicine has up to the present time profited by the researches of chemists upon the aconite alkaloids, due, no doubt, mainly to the uncertainty arising from the varying nature of commercial "aconitines." He recommends that any person setting about the preparation of aconitine for internal administration should satisfy himself that the roots he uses are the product of *A. Napellus*, and that the alkaloid should be separated in a crystalline condition, an operation which is described as requiring ordinary skill helped by extraordinary patience. The nitrate is the salt most ready to crystallize, and from it the pure alkaloid or any of its salts can be prepared without difficulty.

In a paper on the "Composition of Easton's Syrup," Messrs. R. H. Davies and E. B. Schmidt reported the results obtained during an examination of several samples of this preparation. It was found that they varied widely in composition among one another and from a sample prepared according to Dr. Easton's formula, the strychnia, for instance, ranging from 0·6 to 3 grains per four fluid ounces, the theoretical quantity being one grain.

In an interesting paper on the Odorous Principle of Henbane, Mr. A. W. Gerrard reported that he has succeeded in separating this principle as a pale yellow unctuous semi-crystalline mass, which consists probably of a butyric ether. Mr. Gerrard expresses an opinion that the deposit which sometimes forms in tincture of henbane will be found to consist of a mixture of this principle and chlorophyll.

The last paper read was by Mr. J. B. Barnes, and contained Suggestions for Combinations of Collodion, in which a number of instances are mentioned where collodion may probably be used advantageously for the topical application of medicaments.

At the close of the reading of papers, Professor Attfield presented to Mr. Ashton, in the name of the Conference, for the use of the local pharmacists, a number of handsomely bound volumes, purchased from the Bell and Hills Fund, to which were added 'Pharmacographia' and 'Science Papers,' presented by Mr. Thomas Hanbury in memory of his brother. The place of meeting in 1884 was the next business and a cordial invitation from the pharmacists of Hastings to visit that town having been read it was unanimously accepted. The election of Officers for 1883–4 was then proceeded with, the following being the result:—

President.—J. Williams.
Vice-Presidents.—M. Carteighe, London; J. R. Young, Edinburgh; S. R. Atkins.
Treasurer.—C. Ekin, Hounslow.
General Secretaries.—F. Baden Benger, Manchester; S. Plowman, London.
Other Members of Executive Committee.—J. Borland, Kilmarnock; J. C. C. Payne, Belfast; W. A. H. Naylor, London; W. V. Radley, Southport; W. Hills, London; G. S. Taylor, London; J. C. Thresh, Buxton; J. B. Stephenson, Edinburgh.
Auditor.—T. H. Sykes, Southport.

All that now remained to be done was to pass a well-deserved and enthusiastic vote of thanks to the Local Committee,—and especially to Messrs. RADLEY, ASHTON, BALL and KERSHAW,—for the admirable arrangements made to secure the success of the Conference; another to the public bodies and private firms that had thrown open their establishments to the visits of the members; and lastly one to the President for his services in the chair. After the Conference had terminated a large number of members adjourned to the splendid Glaciarium, where a number of skaters were disporting themselves on a surface of ice. The process of ice-making which is here brought into play was described and shown. It consists in the vaporization of liquid sulphurous acid in a partial vacuum produced by pumps worked by steam; the reduction in temperature thus produced is communicated to a solution of magnesium chloride flowing through a series of pipes under the floor of the Glaciarium, and the water is thus maintained in a frozen condition.

On Thursday a party of eighty, on the invitation of the Local Committee, left Southport by the 8.10 a.m. train for St. Helens. Special saloon-carriages were provided for the accommodation of members. The weather was, unfortunately, as unfavourable as it well could be. The rain poured down persistently, and a thick mist obscured the view of the country. On nearing St. Helens, hundreds of chimneys and mine-wheels suddenly appearing and disappearing in the gloom produced a most weird effect. On arrival at St. Helens the party divided, the majority proceeding to Messrs. KURTZ and Co.'s Chemical Works. Here LEBLANC's process for making sodium carbonate; processes for making caustic soda, bleaching powder, potassium chlorate, etc., were shown, and the principles involved and details of manufacture were explained by several most courteous guides. The other members visited the Union Plate Glass Works, BISHOP's Flint Glass Works, and Messrs. BIBBY and SON's Copper Smelting Works.

The Union Plate Glass Works stand on ten acres of ground, and employ a large number of hands. The operation of casting was not going on, but the immense cast iron beds—nine inches thick at the side, and twelve inches in the centre — on which the plates are cast were shown. The cast plates of glass are annealed for about four days in flat ovens and are then ground. The first grinding is with sand, the plate being cemented to a heavy bed with plaster of paris, and a heavy iron plate as large as the glass, being moved back and forth and sideways on the surface by machinery. The next process is similar, but two plates of glass are placed together with emery between, thus grinding each other. This produces a smooth opaque surface, such as is used for door panels, etc. The third grinding is with rouge and felt, which produces a fine polish. The rouge is made by the firm, by roasting copperas.

Space will not allow us to give further detailed account of the various processes exhibited at these places, but it should be stated that Messrs. BIBBY and SONS delayed the completion of the final stage of the reduction in order to give the members present an opportunity of viewing it. Luncheon was partaken of at the "Fleece," where Mr. Alderman HARRISON occupied the chair. Mr. S. R. ATKINS, of Salisbury, in most felicitous terms proposed the Alderman's health, a toast which was cordially received and responded to in appropriate terms. The return to Southport was made at 12.45, so that members might be able to attend a garden party given by the Local Committee at the Botanic Gardens, Churchtown. The rain, if anything, had increased in the meantime, but this did not prevent upwards of four hundred ladies and gentlemen being present. They were of course confined indoors, but good entertainment was provided for them in the spacious conservatory by a company of CHAS. HALLÉ's Choir, who sang a number of part songs, glees and choruses. Mr. LEO GRINDON delivered to the general audience a popular lecture on some interesting plants, and exhibited to the scientists, more especially, some beautifully mounted specimens of rarities of the vegetable world. The Fernery and Museum also attracted numerous visitors, and so the time slipped pleasantly by. Just before the breaking up of the party, the weather cleared up somewhat and enabled the members and their friends to view the extensive gardens and ornamental water. Finally, the gathering broke up soon after six amid general expressions of pleasure derived from the meeting, and of appreciation of the efforts so successfully made by the Local Committee for the entertainment of the visiting members during the whole of their visit to Southport.

THE BRITISH ASSOCIATION.

WITHIN two or three hours of the close of the Pharmaceutical Conference the inaugural meeting of the British Association in Southport was commenced in the Pavilion of the Winter Garden. The attendance was very large, for seldom, if ever, has there been a wider spread desire evinced to be present at the delivery of the Address by the incoming President. This feeling can hardly be explained upon intelligible grounds, for there was a general expectation that much of the oration of Professor CAYLEY would be *caviare* to the majority of his audience, an expectation which was justified by the event, notwithstanding the omission of some of the profounder passages. It is our intention, in accordance with the practice in preceding years, to print the address *in extenso*, but the length of the report of the Conference proceedings necessitates its postponement until next week. On Thursday morning the proceedings in the different sections commenced with addresses from the respective Presidents, that delivered by Dr. J. H. GLADSTONE in the Chemical Section having for its subject the nature of the elements. In the Report of the Council presented to the Executive Committee it was stated that 445 old members have notified their intention to be present at the meeting in Montreal next year and 55 persons have either become members or expressed a wish to do so, with a view of taking part in it.

DEATH OF MR. ATHERTON.

IT is with great regret that we announce the death, on Saturday last, at Tunbridge Wells, of Mr. JOHN HENRY ATHERTON, who was a member of the Council of the Pharmaceutical Society from May, 1870, until May, 1878. We understand that Mr. ATHERTON had been suffering severely for some weeks past from a malignant tumour, but that, nevertheless, his death was somewhat sudden and unexpected.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The proceedings of the Twentieth Annual Meeting of the British Pharmaceutical Conference commenced on Tuesday morning, the 18th inst., at the Prince of Wales Hotel, Southport, Professor Attfield, F.R.S., President, in the chair. The attendance of members and friends was as large as on any recent occasion, the capacity of the room set apart for the business of the meeting being taxed to the utmost.

Welcome to the Conference.

Mr. Radley, Chairman of the Local Committee, commenced the proceedings by welcoming the Conference to Southport. He said that the chemists of the town and district had been looking forward to this meeting with great pleasure, and it was their supreme desire that it might be a happy and successful gathering. Their pleasurable anticipations were awakened not only by the interest and instruction to be derived from the various papers and discussions, tending to advance those departments of science and art in which pharmacists were most directly interested, but more especially because this meeting afforded the opportunity of making the personal acquaintance of many gentlemen whose names had long been familiar to them, and at their head, Professor Attfield, whose works were well known and appreciated, not only in Great Britain and Ireland, but also on the Continent and in the United States. Southport was a young town, which had grown rapidly, and, as all knew, was not unwilling to make its vitality manifest by a little warfare, but it was not able to boast of any great treasures in the way of arts or manufactures. Their neighbours at St. Helen's, however, had kindly come to their aid, and on Thursday morning a visit would be made to some interesting works there. Naturalists would, it was hoped, find various objects of interest in the neighbourhood, and the Winter and Botanical Gardens, Glaciarium, and Baths would help to interest the visitors.

The President, in the name of the visiting members of the Conference begged to thank the members of the Local Committee, for their hearty welcome, and to assure them that it was accepted with as much earnestness as it was offered. They considered themselves fortunate in having the opportunity of visiting so thriving and interesting a town—one which had the great advantage of attracting to its shores and charming boulevards the pleasure-seeking portion of a population of no less than four millions within a radius of forty miles. He would also thank the Committee for the enthusiasm with which the idea of this visit had been received, and he trusted that before the meeting closed the local members would find, by the frankness and fulness with which the visiting members accepted their hospitality, how highly their sympathetic efforts were appreciated.

Mr. F. Baden Benger (Secretary) then read letters from Mr. Brady and Mr. Greenish, expressing their regret at not being able to be present, and stated that similar communications had been received from Professor Redwood, Messrs. Umney, Martindale, Cutting, Denzil, Kinninmont, Maben, Gerrard, Barnes, H. Long, Groves, and H. G. Greenish.

List of Delegates.

The following is a list of delegates from various societies, who were present at the meeting:—

From the *Pharmaceutical Society of Great Britain.*—Mr. S. R. Atkins (Vice-President); Messrs. E. N. Butt, W. Hills, W. V. Radley, W. D. Savage, G. F. Schacht and J. Williams.

From the *North British Branch of the Pharmaceutical Society.*—Mr. J. Nesbit (President); Messrs. J. Borland, D. B. Dott, D. Frazer, J. B. Stephenson and J. R. Young.

From the *Pharmaceutical Society of Ireland.*—Messrs. J. E. Brunker, F. J. Minchin, J. C. C. Payne and W. F. Wells, jun.

From the *School of Pharmacy Students' Association.*—Professor Attfield.

From the *Bristol Pharmaceutical Association.*—Mr. G. F. Schacht.

From the *Glasgow Chemists and Druggists' Association.*—Messrs. D. Frazer, E. C. C. Stanford and J. Nicol.

From the *Leeds Chemists' Association.*—Messrs. George Ward, R. Reynolds and P. Jefferson.

From the *Liverpool Chemists' Association.*—Mr. J. Woodcock (President); Messrs. E. Davies, C. Symes and A. C. Abraham.

From the *London Chemists' Assistants' Association.*—Mr. W. A. H. Naylor.

From the *Manchester Chemists and Druggists' Association.*—Messrs. Wilkinson, Robinson, Paine, Benger, Siebold, A. H. Jackson and Woolley.

From the *Oldham Chemists' Assistants and Apprentices' Association.*—The President.

From the *Sheffield Pharmaceutical and Chemical Society.*—Messrs. J. M. Furness, G. T. W. Newsholme and W. Ward.

Report of the Executive Committee.

Mr. Sidney Plowman (Secretary) then read the Report of the Executive Committee as follows:—

It is the duty of your Committee in this, their Twentieth Annual Report, to place before the members of the Conference an account of the business transacted by them during the past year.

Beside the ordinary details of administration, several questions of great interest to members have arisen, upon which your Committee have had to deliberate on your behalf.

It will be remembered that no decision as to the place of meeting for 1883 was arrived at by the General Meeting of the Conference at Southampton last year, but it was resolved that the selection should be left in the hands of the Executive Committee. The British Association, owing to unforeseen circumstances, was unable to visit Oxford, and had not at that time selected the place in which it would meet in 1883. At a meeting of your Committee in October last year, letters were read from both Oxford and Southport, inviting the Conference to meet in those towns in 1883. As, however, in the meantime the British Association had selected Southport as their place of meeting, and as it is the practice of the Conference to meet in the same town as the British Association, it was unanimously resolved that the Southport invitation be accepted. At the same meeting the question of local arrangements was raised, and the following resolution was passed:—

> "That it be a general instruction to the local committees of towns in which the Annual Conference is to be held, that their arrangements, both in respect to the business of the Conference and the entertainment of its members, be approved by the Executive before publication, and that the attention of local committees should be called to the report of the Executive at the Sheffield meeting, in so far as it relates to questions of entertainment."

At a subsequent meeting of the Executive Committee, in April, 1883, it was decided that the list of subjects for investigation should be revised, and, in order to carry this out, it was resolved that a copy should be sent to every member of the Committee inviting suggestions. As a result some subjects were excluded and others added, and the "blue-list" last issued includes those subjects only which possess greater or less special pharmaceutical interest.

At the same meeting the General Secretaries were instructed to issue to all registered chemists and druggists residing in Great Britain and to all pharmaceutical chemists of Ireland not already members of the Conference, a circular prominently setting forth the objects of the Con-

FINANCIAL STATEMENT FOR THE YEAR ENDING JUNE 30, 1883.

ference, and inviting them to membership. This instruction was carried out in July at a cost of £92 11*s.* 7*d.* As a result, between 340 and 350 registered chemists have tendered their subscriptions and presented themselves as candidates for membership, and applications continue to arrive almost daily.

As the financial year ends on June 30th no account of the cost of, or of new subscriptions due to the issue of, the circular is included in the Treasurer's present financial statement.

The result of the distribution of the "blue-list" and other circulars among the pharmacists of some of the colonies has been so encouraging that the question of the desirability of appointing colonial secretaries has been discussed.

It was considered that the objects of the Conference, viz., the advancement of pharmacy and the promotion of brotherly feeling and mutual goodwill, might be best secured by such appointments, and the General Secretaries were instructed to obtain the names of suitable gentlemen in the Colonies and India willing to undertake the duties. The following have been communicated with:—Mr. H. S. Evans, F.C.S., Montreal, for Canada; Mr. W. C. Ross, Trinidad, for the West Indies; Mr. A. Walsh, Port Elizabeth, for the Cape and Natal; Mr. D. S. Kemp, Bombay, for India; Mr. E. Taylor, Brisbane, for Queensland; Mr. H. Shillinglaw, Melbourne, for Victoria; Mr. L. B. Bush, Bathurst, for New South Wales; Mr. A. P. Miller, Hobart Town, for Tasmania; Mr. T. M. Wilkinson, Dunedin, for New Zealand. Sufficient time has not elapsed for replies to be yet quite complete, but so far as they have at present been received they are most favourable. Mr. Kemp advises the appointment of a secretary in each Presidency instead of one only for the whole of India and consents to act for Bombay if appointed; but Mr. Evans in consenting to act for Canada thinks one secretary sufficient for the whole of the Dominion.

Your Committee have pleasure in reporting that they have been able to accede to three applications for money grants for the purchase of material on which to conduct researches. They are as follow:—£5 to Messrs. Dunstan and Short to investigate the pharmaceutical preparations of nux-vomica, principally in regard to their alkaloidal value; £5 to Messrs. Dunstan and Ransom to further extend the method of alkaloidal extraction with the chloroform-alcohol mixture, to be followed by a further grant of £5 if required; £2 2*s.* to Mr. W. Elborne to determine the comparative pharmaceutical value of commercial rhubarb.

Reports will be presented at this meeting from Messrs. Greenish and Jackson on subjects for the elucidation of which grants have previously been made, and a first report from Messrs. Dunstan and Short on the preparation of nux-vomica, as well as one on the quantitative separation of strychnine and brucine, will be read at this meeting. Mr. Elborne will present a report on the comparative value of commercial rhubarb at the next general meeting.

Twenty-three papers and reports have been received for the present meeting, but one was of a purely medical character and was returned to the author as being unsuited for the object of the Conference.

The Bell and Hills Fund, founded by the munificence of Mr. Thomas Hyde Hills, provides for the annual expenditure of £10 for the purchase of books for presentation to the library of the Pharmaceutical Association of the city or town in which the Conference meets from time to time. As Southport has no such association some difficulty arose as to the gift of books this year. The Local Committee, however, arranged that, if the Executive Committee could make the grant, the books should form the nucleus of a library and that the Local Secretary of the Pharmaceutical Society of Great Britain, for the time being, should undertake the charge of them and should guarantee their legitimate use. Under these circumstances it was decided that the books be presented and they are now on the table for the inspection of members.

Mr. Louis Siebold was last October re-appointed editor of the 'Year-Book,' and the manuscript, as far as it can be prepared, is now on the table.

Since the last General Meeting at Southampton, 396 candidates have been elected to membership, 20 of whom reside in the Colonies, 14 in Ireland, and 332 of the applications were sent by residents in Great Britain in response to the special circular issued last July.

Financial Statement, 1882–3.

Mr. Ekin (Treasurer) read the Financial Statement, which is printed on the preceding page.

The President moved the adoption of the report, which he said spoke for itself, and showed that the Committee had kept constantly before it the objects of the Conference, viz., the encouragement of original research, and the promotion of good fellowship amongst its members throughout that Greater Britain on which the sun never sets. It would be open to any one to put any questions with regard to it, or to discuss it in any way.

Dr. Quinlan seconded the motion, and thought the members ought to be much obliged to the gentlemen who had managed their affairs so well.

No questions being asked the motion was put and carried unanimously.

The President's Address.

The President then delivered the following address:—

The Future Supply of Drugs to the Public.

Part II.

The Relation of the State to Pharmacy.

Once more I desire to direct attention to the important question of The Future Supply of Drugs to the Public. The one side of that subject, namely, The Relation of Pharmacy to the State, I treated last year in my address to the Members of the British Pharmaceutical Conference assembled at the Nineteenth Annual Meeting, at Southampton. Again honoured with the Presidency of that body, at the Twentieth Annual Meeting, at Southport, I ask for attention to the other side, namely, The Relation of the State to Pharmacy.

I do not now purpose considering the ideal relationship of a State to Pharmacy. Nor can I within the limits of an hour's address give even an outline of the actual relationship now existing between every civilized State and the pharmacy of that State. I must confine myself at Southport, as at Southampton, to the question as to what will be the character and conditions of the supply of drugs, in the immediate future, to the individuals and households of Great Britain, so far as that character and those conditions can be predicated from the character and conditions of the present supply. What pharmacy is doing and can do for the State, in the interests of every individual in the State, I described last year; what the State is doing and can do for pharmacy, in the interests of the public, is what I now desire to consider.

A crisis in pharmacy is fast approaching. The endeavour of the British Legislature to provide for the proper supply of trustworthy drugs to the public is being seriously thwarted. The great importance of such a supply is obvious, and in 1868 Parliament enacted that after the end of that year no person should take the title "chemist and druggist," and practise under it, unless, after satisfying State Examiners that he was properly qualified, his name was duly enrolled on a State Register. Now, that it was possible for any person probably utterly unqualified and certainly unregistered to act towards the public as a chemist and druggist without actually calling himself or using the words "chemist and druggist," was not then foreseen. Yet that is exactly what is happening. The practice which has long existed in this country, especially in thinly populated districts, of some general shopkeeper, usually a grocer, selling two or three common drugs, a practice itself not always harmless, has, within the past five or ten years, developed into the sale of nearly all drugs and medicinal compounds by shopkeepers of all descriptions in nearly all districts. Indeed, in some cases, also increasing in number every year, completely furnished shops, indistinguishable in appearance from those of registered chemists and druggists, are opened by unregistered and unqualified men, who are mere distributors in retail of drugs bought wholesale; men without proper knowledge respecting the dangerous articles they deal in and without any sense of the responsibility of their position. These sham chemists and druggists, and large numbers of the general shopkeepers alluded to, sell everything the properly qualified chemist and druggist sells. The only articles which they are not supposed to sell are the few more virulent poisons scheduled in the Pharmacy Act, the sales of which, however, by the duly qualified man do not make five pounds difference to him in the course of a year.

This condition of things is not only worse than that which the Pharmacy Act of 1868 was intended to remedy, it is very much worse. For to supply such unqualified drug sellers large numbers of so-called wholesale druggists have sprung into existence respecting whose qualifications for the work nothing is known. So that at the present time the public are not only liable to be supplied with untrustworthy drugs because a flaw in an Act of Parliament allows unexamined and unregistered men to practise as chemists and druggists, but because the wholesale druggist supplying such retail vendors may himself be incompetent. Now, from wholesale druggists, men who do not keep open retail shops, the Legislature never has demanded evidence of qualification. For, firstly, the old type of wholesale druggist was a man of probity beyond suspicion—and, fortunately for the health of Great Britain, the old firms still exist, many a new one, doubtless, being as good. But, secondly, on the assumption that drugs and compounds are only supplied retail by persons who have given evidence of their fitness to manipulate such potent substances and to judge of their quality as they are sent into the shop from the warehouses of wholesale dealers—the assumption on which, apparently the Pharmacy Act of 1868 was framed—on this assumption any evidence of qualification of wholesale druggists is uncalled-for and unnecessary. Obviously, if all the retailers were qualified, the public would be amply protected. Indeed, considering the number of persons employed in a large wholesale drug house, and the extent to which division of labour is carried in such an establishment, the supplying of evidence of qualification of all who carry on different responsible operations there is perhaps not practicable. So that if any remedy is to be sought for the serious state of things I am considering—assuming that it exists, and I shall show that it does,—that remedy will scarcely be found in the requiring of evidence of qualification from wholesale druggists. It rather lies in an improvement of the Pharmacy Act as regards the retailers of drugs; but of this more later on. The serious fact for present consideration is, that whereas the law of this country, in view of the welfare of the community, in drug matters, contemplates the retail supply of drugs by properly qualified persons only, that intention is being extensively frustrated. Drugs of nearly all kinds, simple and compound, are being indiscriminately stored and sold by unqualified persons; stored with articles of food and drink, and indeed with nearly all articles required in domestic life; and sold by shopkeepers of nearly every class. Thus, drugs, besides being manipulated and vended by registered chemists and druggists, and sometimes by medical men who cannot in all cases earn a livelihood without turning their surgery into a shop, are stored and sold by barbers, booksellers, chandlers, confectioners, drapers, general dealers, grocers, hairdressers, herbalists, ironmongers, marine-store dealers, oilmen, printers, publicans, stationers, store-keepers, tailors, tobacconists, toy dealers, wine merchants. Many of these shopkeepers are no doubt in a very small way of business; many, however, are prominent men doing large trades, and too often sell the drugs at cost price as mere baits to catch customers for other, profitable, transactions. Then, as already indicated, besides these drug-sellers admittedly engaged in other trades, there are the sham chemists and druggists, the coloured show-globes in whose windows, and bottles on whose shelves mutely proclaim them chemists and druggists, but who are unregistered and unqualified.

This, I say, is an extremely serious state of things. It is, of course, an unfair and very serious condition for chemists and druggists themselves,—men who have fitted themselves for their responsible calling in the manner prescribed by Act of Parliament,—for they are thus, many of them, losing much of their means of living and of the means by which they maintain their wives and families. But it is far more serious for the public.

It is a serious state of things for the public for this chief reason, namely, that whereas purchasers of food are more or less protected from the purchase of bad food by their personal power of judging of the quality of food, purchasers of drugs cannot be protected from the purchase of bad drugs by any personal power of judging of the quality of drugs. *Caveat emptor* does not apply in the case of drugs, because the purchaser has not the requisite knowledge to enable him to *beware*. Even the aid which purchasers of food can invoke from officials under the Acts relating to adulteration cannot be obtained in the case of drugs, because, amongst other reasons, nature yields drugs which vary much in quality, and only trained chemists and druggists can properly judge of such quality. Analysts *quâ* analysts cannot be sufficiently familiar with the varying natural standards of quality of all the many medicinal articles comprehended under the term *materia medica*—if, indeed, there are any such standards—to throw their official shield in front of the public. From the evils of bad drugs the public cannot protect themselves; they cannot be protected by the machinery of the Food and Drugs Act; they have no control over either the importer of foreign drugs, the grower of indigenous drugs, or the wholesale dealer in or manipulator of drugs; as regards the retail dealer, the machinery for their protection in the Pharmacy Act is incomplete: therefore it is expedient that the machinery for their protection in the Pharmacy Act be rendered complete and effective.

Here let me endeavour to allay any alarm which the use of the word "protection" may excite in the minds of free traders. And, I say, first, that where the health of the public is at stake, and where the public cannot protect themselves, an exception to the rule of free trade may be and is allowed. For already the State does not permit free trade in some poisonous drugs. Therefore an exception to the rule of free trade is already allowed in pharmacy, hence this part of the question need not be discussed. It is only necessary to consider where the limit of exception should be fixed. The line is now drawn by the State between some poisons and others. My contention will be, that the line should encircle all poisons. Nearly all drugs are poisons, more or less. Therefore nearly all drugs should be excluded from the area of free trade. But I say, secondly, that the doctrines of free trade do not apply to pharmacy. There cannot well be true freedom of trade where the power of judging of the article traded in or demanded is all and only on one side. It is for this obvious reason that the spirit of free trade has not been and cannot be applied to those avocations commonly termed professions. The inhabitants of civilized countries having desired legal or medical assistance, and well knowing that they were unable to form any immediate judgment of the quality of that assistance, have looked for and obtained external means of protecting themselves from bad law and bad medicine—means external to themselves. Such communities have required that lawyers, doctors, and others should give some evidence of qualification to official examiners, or have aided professional men to erect certain social barriers, known as etiquette and the power of the cold shoulder, for the exclusion of quacks, charlatans, and other unqualified persons from their ranks. Now, pharmacy is largely a professional avocation. In pharmacy we are on the border line of the commercial and the professional. Pharmacy is partly a trade, partly a profession. The purchase and sale of an ounce of tincture of rhubarb is *per se* a transaction purely commercial. But if the dose is asked, or, say, the mode of administering the medicine, the transaction assumes a professional character; while the still more important question as to whether the purchaser is supplied with a trustworthy or worthless article turns entirely on the vendor's professional knowledge—chemical, botanical, and pharmaceutical knowledge. In those subjects of professional knowledge he is educated; in those subjects of professional knowledge he is examined; to the extent to which he possesses that knowledge, to that extent he is a professional man. Trade and profession form the warp and woof of pharmacy, interwoven in every part of the fabric. The doctrines of free trade cannot, I say, be applied to professions. Therefore the principles of free trade cannot be applied to pharmacy. The purchaser of drugs cannot protect himself from the purchase of bad drugs. He is not, himself, in a position of freedom in this matter. Therefore he needs protection by methods external to himself. The most ardent champion of freedom will, I am sure, recognize this principle. The Legislature has recognized it, and the public has recognized it, and it has been applied to the practice of pharmacy as to medical and to legal practice, not by excluding unqualified chemists and druggists from practice by a code of etiquette or unwritten social law—for, unfortunately, that method appears to be inapplicable in pharmacy,—but by rendering illegal the use of the name or title "chemist and druggist" by unexamined or unregistered men.

The Pharmacy Act of 1868 was, at all events, intended to provide such protection. It has partially failed, because incomplete; failed because, while requiring that chemists and druggists shall be properly educated, it has not prevented the uneducated from palming themselves off as chemists and druggists. The Act practically says sellers of drugs must be properly educated, yet allows uneducated vendors to sell drugs. The failure has arisen from a wrong method of protecting the public having been adopted,—a method which could not be foreseen to be wrong, but which has proved wrong in the working. The method adopted was that of raising a legal fence around the mere name "chemist and druggist;" the method which should, we now see, have been adopted, was that of rendering illegal the retail sale of the simple and compound drugs of the British Pharmacopœia (with certain exceptions) by any but registered chemists and druggists, with the saving of all rights, of course, to medical practitioners.

The time has come when, for the welfare of the public, the Pharmacy Act should be rendered efficient. If this be not done, a period will soon arrive when the public, unable, as I have said, to judge of the quality of drugs for themselves, will be deprived—or a great majority will be deprived—even of those external means of protecting themselves which, in most districts, they possess now; that is to say, they will lose the advantage of dealing with duly educated men; for thoroughly and legally qualified druggists will only be found in the more wealthy quarters of cities. A certain proportion of drug vendors will always, for various reasons, qualify themselves. A certain proportion of any class of men are always ready to undergo, voluntarily, a course of special education with its attendant set of examinations. Pharmacists form no exception to this rule. Before compulsory examination was instituted in pharmacy,—that is, before 1868,—about 25 per cent. of the chemists and druggists of this country voluntarily submitted to pretty much the same examination that all who would now call themselves "chemists and druggists" are compelled to pass. And therefore, even if the present tendency for the retail supply of drugs to pass into unqualified hands were allowed to continue, a few well-qualified chemists and druggists would, for various reasons, be forthcoming. These would no doubt place themselves and their shops amongst the wealthier classes in the west ends of towns and in fashionable watering places, and such classes of the public would thus be duly protected from bad pharmacy. But other classes would be unprotected from the liability to be supplied with bad, weak or spoilt drugs for daily needs or possibly for critical times when life and death are on the balance. Such a state of things must soon come to pass unless timely legislative action be taken. I say a crisis in British pharmacy is fast approaching.

But before we further consider the question of remedy, evidence must be adduced in support of the assertion that potent drugs are being sold largely in nearly all parts of the country by unregistered persons. Evidence of this kind I have gathered from about two hundred different districts in England and Scotland—districts fairly representing the whole of Great Britain. I have been supplied with direct evidence, in the form of price lists of all the important drugs in general demand issued to the public by shopkeepers other than registered chemists and druggists, and in the form of statements from competent observers as to the kind and numbers of unqualified traders who vend drugs in their respective localities. Indirect evidence has been given to me in the form of returns showing the depreciation in the value of chemists' businesses, including the cause of that depreciation, during the past five or ten years.

In November last I sent to correspondents in about three hundred districts copies of a letter the chief paragraphs of which were as follows:—"I desire to show that it is to the direct interest of the public that something should be done to prevent the rapidly increasing sale of drugs by unregistered and incompetent persons—an irregular form of trade which is said to have produced already, or largely contributed to the production of, a seriously depressed condition of retail pharmacy. To this end it is desirable I should have more exact knowledge of the stated depression, and of its extent, than any single individual can at present possess. May I beg you, therefore, in the interest of yourself and your fellow pharmacists, to help me by telling me how far the oft-recurring statement that 'pharmacy is not what it used to be,' is true in your experience. For example, how far, in your judgment, is a business worth less than formerly: how far, in your district, are drugs sold by grocers, drapers, etc., or by unregistered men pretending to be chemists and druggists: what proportion of an average drug business in your vicinity is pure pharmacy as compared with the part that has little or nothing to do with drugs; and is the pharmaceutical portion increasing or diminishing? Do you think that the taking of fewer or more concentrated medicines by patients affects the question; or that the depression in pharmacy is greater than has occurred in most callings of a general business character during the past few years? Can you throw any other light on the matter?"

The correspondents selected were, first, a chemist and druggist in most towns in Great Britain having one or more Members of Parliament or containing three Members or Business-Associates of the Pharmaceutical Society of Great Britain; second, representative pharmacists whose acquaintance I have made in my visits for twenty consecutive years, to the twenty towns at which the British Pharmaceutical Conference has assembled; thirdly, two or three different classes of persons not actually engaged in retail pharmacy, but who have daily dealings with retail pharmacists. Of the three hundred correspondents I addressed, about two hundred, either at once or on a second application, sent me full replies to the questions, many offering to contribute any further information that might be desired. The greater portion, indeed practically all the replies were, as might be expected, so far private that while I am at liberty to make public use of the information they conveyed, I am not authorized to give the names or addresses of the writers. I thank them cordially for their help, and I doubt not that were any public inquiry into the relation to each other of the State and Pharmacy to be instituted, by a Royal Commission, by a Committee of either House of Parliament, or by any other authority, the majority of them would be willing personally to substantiate their statements.

Respecting the evidence which price lists afford of the sale of drugs by tradesmen other than druggists, little need be said. Every retail trader, who, finding it expedient to hold to the fiction that number one is the first law of nature, proceeds to roll three or four, or, it may be ten or twelve businesses into one, is impelled by convenience to compile, and by policy to publish, a priced list of his many articles of sale. Most householders in this country have probably received many such lists sent to them by way of advertisement. In these lists drugs are commonly included. Every drug in ordinary demand will be found there except the few very powerful poisons scheduled in the Pharmacy Act. Indeed even these are not actually excluded, for, called, not by their own names, but by some fancy title, and classed under the misleading term "patent medicines," even the most virulent poisons are sold by these unregistered persons.

Not only, however, do such price lists afford evidence of the sale of drugs by traders other than druggists, but, the prices quoted showing only a slight trading profit above the wholesale price, the inference is fair that such vendors are as professionally unqualified as they certainly are legally unqualified, that is, unregistered. For a 5 or 10 per cent. profit may, possibly, remunerate the man who is only a trader—indeed who does not aspire to be anything more—such as a grocer or a draper, but is quite inadequate for a duly qualified chemist and druggist, who, in obedience to the demands of the public as expressed in the Pharmacy Act, and to his own sense as to what is right, has gone through a proper pupilage in pharmacy, chemistry, botany, and materia medica. As well might we expect a lawyer to thrive on a 5 or 10 per cent. profit on his stationer's work and his office expenses, or a doctor to flourish on a 5 or 10 per cent. profit on his dispensing work and his surgery expenses. These men must be remunerated for the brain work they do for the public; they are *professional* men. The druggist is in part a professional man, and must *pro tanto* be paid for his brain work. (And here, in parenthesis, I may remark that the public never stigmatize a lawyer or a doctor as "a man who gets elevenpence three farthings out of a shilling," although this pseudo-sarcasm would be far more literally true of either of them, if it were founded on the insignificant amount of their office costs or surgery expenses, than it is of the druggist. The public should not so stigmatize the druggist. They should regard the charge for a bottle of medicine as they regard the charge for a legal deed or for a medical prescription, namely, as a fee. For a fee it is, in every professional sense of the word. And in order that the public may be set right in this matter, I strongly recommend druggists to think and speak and write of their charges for medicines as fees. I do not recommend that such a view of the case be thrust on the public; for although persons are accustomed to pay two fees, indeed a whole series of fees, for their law—fees to counsel, to their clerks, to solicitors, and for stamp dues, etc.—they will say they object to pay two fees for their physic, that is, one to the physician and one to the pharmacist, forgetting that that is what they already do when they obtain medicines of a chemist and druggist whose charges and qualifications are commensurate. What I do recommend is, that when occasion arises the public be reminded that that is what they do, and that, at all events, this view of the matter be put forward by the druggist whenever he is stigmatized as an ordinary tradesman desiring more than an ordinary tradesman's profit. The public having demanded, for their own safety, by means of the Pharmacy Acts, that the retail druggist possess professional knowledge, will not knowingly stultify themselves by treating him as a tradesman only. But to resume my argument.) The public recognize the value of professional services, and not only pay professional men commensurate fees, but are only too glad to find such services at their disposal. Were any man setting himself up for a lawyer or a doctor to offer to charge the public only a trader's price of 5 or 10 per cent. profit on his expenses, he would rightly be suspected of having no professional knowledge for disposal. Just so should a vendor of drugs, who charges only a trader's price of 5 or 10 per cent. profit on the wholesale price of the drugs, be suspected of having no professional knowledge respecting those drugs at his disposal, no such knowledge as those chemists and druggists must possess who are properly qualified according to the Act passed for the safety of the public, namely, the Pharmacy Act. The traders I am now describing charge only a 5 or 10 per cent. profit on the wholesale prices of drugs, therefore they may be rightly set down as not having that knowledge which the public, through the Legislature, has decided that chemists and druggists should possess. Unfortunately, the public, while realizing the position in which they stand to men who are wholly professional, as the lawyer or the doctor, do not realize, and perhaps never will quite realize, the position in which they stand to the real chemist and druggist. For the trading side of his work for the public obscures the professional side. The druggist may do something towards inducing those of the public who raise the question, to regard this matter in the proper light, if he habitually term the charge for medicine prepared from a prescription *a fee*, as I have suggested; but probably not a century of endeavour to educate the whole of the public up to this point of treating him as in part a professional man would be quite successful. Where the public cannot judge for themselves respecting the qualifications of a professional practitioner, even to the extent to which they judge in a general way of the position in which they stand to medical or legal practitioners, there the aid of the Legislature should step in. The public cannot, as regards pharmacy, judge of the pharmaceutical ability of a vendor of drugs. Therefore the Legislature should step in and aid the public by enacting, not only as at present that every man *calling* himself chemist and druggist should be properly educated, but that every man *practising* as a chemist and druggist should be properly educated.

The price lists I have described show, first, that traders whose names are not to be found on the State Register of chemists and druggists *practise* as chemists and druggists. Secondly, they afford presumptive evidence that such traders are not properly qualified. This is a serious state of things for the public welfare, all the more so that the public cannot of themselves detect it.

Moreover, it is a condition of things pervading the whole country. Where the wealthy congregate it is not so obvious: but elsewhere its effect is only too evident, either in the reduction of the number of assistants in a chemist's shop, in the discharge of the one assistant, the conversion of the business into one of another kind, the owner still remaining on the pharmaceutical register, or in the closing of the shop altogether. Indeed, where one chemist's shop has been opened in either of our many new neighbourhoods, one has probably been closed in the older districts; for while population in Great Britain has increased by nearly 11 per cent. during the past ten years, the number of registered chemists has increased in that time only 2 per cent. That number was 13,216 ten years age, last year it was only 13,447. Nay, in view of the fact that some of the chemists and druggists now on the register do not now actually practise pharmacy, it is clear that while the general population has increased, the number of practising pharmacists has probably decreased. Certainly the number has decreased in England, if not in Scotland. What may be the exact significance of annual variations in the numbers on the register cannot perhaps be told until time has removed all who were enrolled by mere declaration before examination became compulsory. The quality of businesses, however — that is, their efficiency for the requirements of the public—has suffered, far more than the number of such businesses. For only too frequently when a druggist's earnings are reduced below the point at which he can afford to keep a qualified assistant, the latter, to earn a living, is impelled to open a small shop somewhere in the neighbourhood and, while earning little from the practice of pharmacy, and probably not more altogether than he formerly received as an assistant, he draws a certain amount of business from his, or some other assistant's, old master, who thereby is brought so much nearer to failure. The new businesses are not all equal in efficiency and general appointments to the old, and the old are depreciated. This action is going on all over the country.

Respecting the kind and numbers of unqualified persons dealing in drugs, the evidence I have received is overwhelming. Of the two hundred and seven replies to my questions, only six state that drugs are *not* sold by unregistered persons in the respective districts, one significantly states "not yet," fifty-five are either silent on the point, or allude to the old practice of grocers in thinly populated districts selling a few of the commonest drugs, while one hundred and forty-five—75 per cent.—complain more or less bitterly of the serious depreciation in the value of their businesses through the sale of drugs by unqualified and unregistered persons. Without wearying my hearers or readers, I will quote from a few of the letters.

And first, as regards unregistered persons whose shops resemble those of chemists and druggists. Comparatively these are at present few in number, but quite sufficiently numerous, and increasing in numbers sufficiently fast, to show that the evil exists and that a remedy may fairly be claimed from the governing body of the State both as the guardian of the interests of chemists and druggists, as of all separate classes, and as the guardian of the welfare of the public generally. But to quote single sentences from some of the letters. No. 1. "In this town we have so-called patent medicine shops . . . where everything except poisons is supplied the same as at a chemist's." No. 2. Here is "an open shop to all external appearance and to the eyes of the public as much a chemist's as any other, though the would-be chemist in it is without any qualification whatever." No. 3. Here "there are two men (unqualified) keeping open shops, who sell drugs, and are generally supposed by the public to be ordinary chemists and druggists." No. 4. "Drugs are sold here to a very great extent by grocers and small dealers, but also in several cases by unregistered men whose principal feature of their business is drugs with the allied articles." No. 5. "We have a few persons pretending to be chemists and druggists, who have no qualification." No. 6. "In this not very populous district we have one unregistered man trading as a chemist and druggist." No. 7. "There is a man within fifty yards of my shop carrying on business as a chemist and druggist who is unregistered." No. 8. "Two men, who failed to pass the qualifying examination under the Act, are now in business in spite of the Act, selling everything except the few scheduled poisons." No. 9. "In a population of thirty thousand about two hundred shopkeepers not chemists sell drugs, as well as two unregistered men acting as chemists and druggists." No. 10. "One man pretends to be, that is, has a shop fitted up like, a chemist and druggist." No. 11. In this not very large town "two unqualified persons' shops have coloured globes in their windows, and present such other appearances that the public cannot distinguish between them and those of registered chemists and druggists." No. 12. "There are several unregistered men in this town pretending to be chemists and druggists." No. 13. "One unregistered man pretends to be a dispensing chemist." No. 14. "We have two shops here kept by unregistered persons. They sell everything just as a chemist does. The public cannot distinguish these shops from those kept by qualified men. The windows, etc., are fitted up like ordinary druggists' shops. I know for a fact that each sells not only ordinary poisons, but the scheduled poisons, though they are too wary to be caught." Could any evidence be stronger than that of these fourteen letters to show that an Act designed for the welfare of the public in a vital matter is being systematically evaded? Here are some twenty-five or thirty cases of persons openly defying the spirit of the Act, and of the clear intention of the Legislature and of the State. From the tone of many more of my letters, I gather that this number of cases might be multiplied considerably. And such evasion of the law must grow if not checked.

As for the evidence my correspondents give of the sale of drugs on a large scale by persons who do not openly pretend to have pharmaceutical knowledge, it is too voluminous for more than a glance. I have already given an alphabetical list of twenty distinct classes of shopkeepers, other than druggists, who deal in drugs. This list is compiled from my letters, all of which agree that the drugs are sold at prices from a little below to 5 per cent. above prime cost, and very frequently as mere decoys, baits, or lures, to entice customers from other shops, and secure them as purchasers of more profitable articles. The prices which the druggist has been in the habit of getting for drugs—and which include payment for his professional knowledge, his special manipulative skill, and his personal guarantee of purity and efficacy —have been pointed out to the public by the traders described, they at the same time drawing attention to their own much lower prices, the inference insinuated being that similar savings (?) would be effected in all other things purchased from them. The unfortunate part of this matter is, I reiterate, that the public cannot, and are never likely to be able to, distinguish between good and bad drugs, or not until the health of the community has seriously suffered, and the livelihood of a large class of respectable citizens has been taken away from them. One writer says that according to the statements of a manager in one of the largest store shops of the kingdom, the drug side of a co-operative store, or store shop, seldom pays *per se*; that even if a loss accrues, the sale of drugs is a cheap advertisement for the rest of the concern; the said manager adding, "Do you suppose we should care for this trumpery return, but that it enables us to say, 'See what extortioners these chemists are; see for yourself that you save threepence or more out of every shilling by dealing with us.'" Co-operative stores are rightly classed by my correspondent with other non-pharmaceutical shops. Indeed, as regards management, they only differ in being carried on by not less than seven owners, while most druggists' shops are carried on by one owner. It seems a monstrous anomaly that the law should allow seven or more men to carry on the business of chemists and druggists, and call themselves chemists and druggists, without being qualified, while it does not allow a single owner to carry on the business of a druggist and call himself a chemist and druggist without being qualified. And, according to the judges, that is what the present Pharmacy Act allows. It is said that a co-operative store company may even sell poisons if no registered assistant is employed, but a single unregistered shopkeeper must not sell poisons, even though he employ registered assistants. Surely there is one law for the store and another for the shop. I could give scores of quotations like the following:—"Grocers, drapers, and others, now sell in this town not only epsom salt, senna, castor oil, etc., but tinctures and other preparations, and, in short, everything but poisons." "Under cover of the patent medicine stamp, poisons such as laudanum, opium paste, and other morphia preparations, are sold here pretty generally by non-pharmaceutical shopkeepers." "So-called wholesale druggists, but who are little more than retailers, supply small outsiders with all drugs, including tincture of opium." "With us the evil of drug selling by non-druggists is growing." "All the small shops here sell packeted goods and paregoric *without opium*!" "Grocers, teamen, and tailors sell so-called patents, packed goods, and proprietary articles as decoys, telling their customers that such things show fair specimens of their prices." "Men other than druggists sell drugs, but the articles I have seen are as low in quality as in price." "At the shops of the drysalters and general dealers in this neighbourhood, there is sold quite commonly, as a remedy for diarrhœa, compound tincture of rhubarb, into which is poured a few drops of laudanum." "At the shops named no doubt the public get supplied with cheap, but, to my knowledge, not with the best drugs."

And now as to the somewhat less direct evidence that "pharmacy is not what it used to be." Only thirteen of the two hundred and seven druggists who replied to my questions could say that pharmacy was as flourishing as ever in their experience. Five of those resided in Scotland, one in the western part of London, and six in the provinces, while the shop of the thirteenth was on one of the smaller islands of Great Britain. One of the provincial six explained that although the chemists of the town were doing as well as ever, they had not increased in number in a period during which the town had increased threefold in population. Only four of the thirteen—four in two hundred and seven—could say that pharmacy was distinctly better than it used to be. Three of the four resided in Scotland, the fourth was the pharmacist of one of our smaller islands. On the other hand, more than half of the letters afford unquestionable evidence that pharmacists are very much farther off prosperity than they were ten years ago. The President of one of those many Chemists and Druggists' Associations which exist as much, if not more, for the benefit of the public than of the pharmacists, says, "There is much harass amongst the general body of chemists and druggists." Another representative says, "Pharmacy in this district is much injured and much depressed, and calls earnestly for a remedy in the interests of the public, and in common fairness to ourselves." A third, writing from a large provincial town, says, "The chemists and druggists of the town have had a meeting to consider the subject of your note. Nothing but depression and hopelessness was manifested. To say that pharmacy is not what it used to be is to use a ridiculously mild phrase. It bids fair to be wrecked." A fourth, in another part of England, says, "We are suffering great trials here, and must suffer more unless the dealing and working with drugs is rectricted to druggists." A fifth, in quite another district, says, "Pharmacy in this neighbourhood has degenerated woefully. In a very few years fourteen druggists have become ten; five had the higher title of pharmaceutical chemist, now I am the only one." A chemist in the southern half of London says, "The sale of drugs by unregistered and outside persons is sapping the foundation of retail pharmacy. Within five hundred yards of my shop drugs are being sold at about 2½ per cent. profit, by four grocers, five oilmen, two herbalists, four hucksters, one saddler, three corn-dealers, one publican, and one ironmonger. . . . For the last six years my returns have steadily fallen one hundred pounds a year. A similar or worse result would be shown by my pharmaceutical neighbours." Of one town of fair size the statement is made that "pharmacy is being obliterated here; we are becoming general dealers." I could give scores of similar quotations.

In answer to my questions as to how far a business is worth less than formerly, one hundred and fifteen of my correspondents put the depreciation at an amount varying from 25 per cent. to 50 per cent. in ten years. Many gave me, in confidence, figures which showed that the loss in value was still greater. Businesses in wealthy districts appear to maintain their value chiefly because their scarcity produces a little competition for them. One correspondent, of great experience, says, "Ten years ago a business then returning £1500 or £1000 a year would readily command £500 or £300 for goodwill, but now with difficulty would realize £150. Those with returns below £1000 and above £500 a year would then fetch £200 for goodwill, but now are transferred for the mere value of stock and fixtures. Businesses turning over, annually, sums below £500 a year, were formerly worth £100 for goodwill; now hundreds of these are in the market quite unsaleable at any price." Another writer of equally wide experience says, "With the exception of one or perhaps two businesses to be found in good towns, all have very materially suffered during the past ten years." A third states that "Businesses in these counties often sell for one-third of what they would have fetched a few years ago, while for many it is difficult to get premiums at all." A chemist in the suburbs of a large city says that "pharmacy is rapidly leaving many suburban druggists. . . . The oilman and grocer and the stores are gradually destroying pharmacy. . . . A blue pill and black draught, lenitive electuary, essences, tinctures, syrups, all kinds of pills, are sold retail at prices for which I could not make the articles properly." A letter from a metropolitan suburb, densely populated, states that "One business here, estimated twenty years ago to be worth £3000, sold eight years since for £1740; the disappointed purchaser sold it three years ago for £1100; it has changed hands twice or thrice since; it would now be dear at £600. Another business in this great thoroughfare about twenty-two years ago sold for £950; it was purchased eighteen months ago for £540. A neighbour's business was valued three years ago at £800—a well stocked, well kept, double-fronted shop, useful house, good garden—it was sold to a surgeon twelve months ago for £350; its returns are now, perhaps, £300 a year." A writer in a provincial town of over one hundred thousand inhabitants, says, "I fear my account of pharmacy here would be too gloomy to receive credence. We have to eke out a living by some additional business. Altogether we feel most despondent, and I believe any chemist in the town would make a present of his fixtures to any person taking over his business and liabilities." A druggist in a smaller town writes, "Fifteen years ago an announcement that my business was for sale brought me several offers of £500. I had occasion to change my intention. But now I cannot get offers of £100." More than half of my correspondents gave statements to the same effect.

Much more varied are the answers to the question respecting the proportion which in the respective districts the pharmacy proper, of an average business, bears to the part that has little or nothing to do with drugs; while the responses elicited by the inquiry as to whether the pharmaceutical part of the business is increasing or diminishing in amount are less varied. Only in six cases do my correspondents report an absolute increase in purely pharmaceutical business. Four report an increase in returns but a decrease in profits; they have had to do more work for less wage. Several reporting a decrease both of returns and of profits, yet state that the relative returns from the pharmaceutical as against the non-pharmaceutical part of the business have increased, the explanation being that while some of the pharmaceutical portion has been taken away from them, severe competition has obliged them to relinquish very largely the sale of non-pharmaceutical goods. On the other hand, many having had the sale of drugs taken out of their hands by unqualified traders, have been compelled by the pressure of *res angusta domi*, to cultivate the sale of general goods until they have almost ceased to be chemists and druggists, and have become grocers, oilmen, general dealers, etc. Not a few, indeed, having had their half-professional, half-commercial ground cut from under them by the unqualified and unregistered traders in drugs, and not having the full commercial power and training of their competitors, have lost most of their business, whether pharmaceutical or general. With such a state of things no one will be surprised to learn that different druggists fix the proportion of pharmaceutical to non-pharmaceutical business done in their shops at figures varying from 5 to 90 per cent. Some describe the amount of their drug sales or general pharmaceutical work as "very little," "small," "very small," "very limited." Others say, "We never see a prescription." "We seldom see a prescription." "I only now make up an average of four prescriptions a week, and I am generally credited with having the best business in the town." "There are four druggists here, and we find that latterly we have dispensed about one prescription per head per week."

Many of my correspondents complain of a special feature of unfairness in the competition to which they are subjected by unqualified traders, namely, that these persons often sell drugs of very inferior quality, probably without knowing it, and that the public, in similar ignorance, as readily purchase the almost if not quite useless stuff, tempted, doubtless, by the lowness of price. Unfortunately, very few of such cases can be touched by the Food and Drugs Acts. Only in such an instance as paregoric being sold without the chief ingredient of that medicine, because its active principle is one of the substances legally deemed "poisons," does there appear to be any means of checking the practice complained of, a practice not only unfair to the druggist, but detrimental to the health of the public. Public officials sometimes express wonder as to where all the worthless or partially spoilt drugs go that are frequently exposed for sale in the large wholesale markets. My correspondents could, apparently, give information which would satisfy that wonder.

After all this evidence, I think every one will admit the following propositions. First, that pharmacy in this country, here and there in a fairly prosperous state, and nowhere yet actually *in extremis*, is nevertheless in a very seriously depressed condition. Secondly, that the prominent cause of the depression is the loss of trade in drugs of guaranteed quality and loss of professional practice of pharmacy by the responsible qualified and registered chemist and druggist, and the acquirement of trade in drugs of unguaranteed quality by the irresponsible, unqualified, and unregistered trader. As for the professional practice in drugs lost by the qualified druggist, that has not been acquired by the unqualified druggist, and therefore has been lost to the public. Thirdly, and chiefly, this condition of things is seriously prejudicial to the public welfare.

No doubt other minor causes influence the depression. And these must now be noticed shortly. But they do not in any important degree dwarf the main cause just stated.

Thus, respecting the practice of physicians prescribing more concentrated medicines than were administered formerly, only 19 per cent. of my correspondents think that it affects the question under consideration, 26 per cent. think it does not, and the remainder express no opinion. A few years ago this practice bade fair to diminish the druggist's income, he generally charging for prescribed mixtures a professional fee of a shilling or two rather than a trade price, a fee which custom had made dependent on the size of the bottle more than on anything else, a fee therefore, the value of which was in inverse proportion to the state of concentration of the medicine. But pharmacists have never, for that reason, made the matter a subject of complaint. They have rather pointed out the great danger of patients, nurses, and families being in possession of what were often deadly fluids. And the practice has gradually been relinquished. In my letters cases are still cited, however: such as 32 powerful doses of prussic acid in a single bottle of medicine; undiluted tincture of nux-vomica, or strong solution of strychnia or strong solution of arsenic, in 1 or 2 ounce quantities, so many drops to be taken in water. In one instance a whole ounce of prussic acid, enough to poison seven or eight or more people, was ordered for one patient.

Again, persons take less physic than formerly. Children in health are not now dosed weekly, even with brimstone and treacle, and healthy adults do not as a rule periodically dose themselves. Homœopathy and hydropathy have had their influence in this direction. Medical men have ceased to prescribe those complicated combinations of half a dozen or a dozen remedial agents which could scarcely be dispensed elsewhere than in the well-appointed shop of a chemist and druggist. They rely now rather on a few active principles or on the official single compounds of the Pharmacopœia. Some idea of the degree in which fewer drugs, etc., are prescribed than, say fifty years ago, may perhaps be gathered from the fact that in 1830 the cost of drugs per in-patient per annum at one of our large metropolitan hospitals, St. George's, was 16*s.* 5*d.*; while in 1880 it was less than half that sum, namely, 7*s.* 11*d.* The former figures, however, include sums for leeches, agents now seldom employed.

Speaking of hospitals, there can be little doubt that these and the many other charitable medical institutions supply advice and medicines gratuitously to large numbers of persons who can well afford to pay, not only the medical practitioner for his diagnosis, but the druggist for his physic.

Here is a third minor cause of the depression amongst chemists and druggists. In the place of many of the prescriptions which formerly found their way to the druggist, physicians not unfrequently rely on and recommend proprietary preparations, forgetting, in their laudable anxiety to cure their patients by any or every means at their disposal, that they are thereby not only instructing the public in the art of prescribing for themselves, but also in the art of prescribing drugs which are often procured from neither the doctor nor the druggist; for patients carefully scan prescriptions, read them more easily than patients did fifty years ago, draw their own conclusions respecting those now under consideration, and then consult their grocer's or storekeeper's price lists. This art of self-dosing is further fostered by the advertisers of secret remedies, an art which in the long run is harmful to patient, doctor and druggist alike, and only indirectly profitable to the twenty different classes of non-pharmaceutical shopkeepers who now deal in such things. Popular medical books and magazine articles addressed to the public all contribute to the same end. The result ensues that while the public on the whole take less physic than formerly, large numbers of those who do take such medicine, take it in a manner over which neither doctor nor druggist has any control. Not a little of this result is due to what I conceive to be mistaken policy on the part of medical practitioners. Verbally and through the press they never cease denouncing the druggist for compliance with a customer's request to be recommended a simple remedy, a practice commonly called counter prescribing, forgetting that they are thereby not only directing customers away from the druggist, but shutting the doors of their own consulting rooms to thousands of patients who had they not been thus prevented from seeking advice of the druggist would have been told by that useful functionary that the case was one demanding treatment by a medical practitioner. Most druggists can tell of many cases in which serious illnesses have probably been prevented and even life saved by their timely recommendation to the person to obtain the aid of a medical man. Besides, if you debar the public from seeking a simple remedy at th druggist's counter, either by medical denunciation or by turning over drug dealing to co-operative stores or to profit-cutting general dealers, you not only do not prevent prescribing by others than medical men—for the public always did and always will prescribe for themselves in their own way, either with or without the aid of a druggist—but you play straight into the hands of the patent-medicine monger, and the maker and distributor of secret remedies; you weaken the pharmacist and the physician; and you do harm to the physic-takers themselves. In the interest alike of pharmacist, physician and patient, this patent medicine question needs careful consideration, with a view to reform. Patent medicines may and do contain on the one hand powerful poisons, and on the other useless substances. The well-trained druggist either already knows or can form a shrewd judgment of the nature of these officially stamped articles, and, by timely caution or advice, can prevent much mischief resulting from the careless or ignorant use of a potent remedy, or from a too thoughtless reliance on worthless materials. No other shopkeeper has similar knowledge. The sale of patent medicines should, therefore, be restricted to qualified and registered chemists and druggists. By-the-bye, the pseudo-official character or guarantee and implied value given to these articles by the presence on them of "the government stamp" should be removed altogether by the withdrawal of the stamp, a substitute for the revenue it produces being found in a greatly increased charge for the licence to sell patent medicines, and perhaps a charge for a licence to sell all other medicines. Such a change would not be unpopular with druggists.

Another minor cause of the depression in pharmacy is found in the fact that many chemists and druggists have thoughtlessly encouraged the purchase wholesale and distribution retail of what are termed packed or packeted goods—be they patent medicines, proprietary preparations, simple or compound drugs, coated pills or what not—instead of themselves preparing such articles; not foreseeing that they were, so far, transforming themselves from professional men into mere trade agents, and that goods of that kind once established in trade could as easily be dealt in by non-pharmaceutical as by pharmaceutical agents, and would only command agents' profits. Such men also have not foreseen that to the extent to which druggists thrust all trouble and responsibility, whether as regards packeted drugs or any other drugs or compounds, on to the wholesale druggist, who, by the way, may or may not be a competent pharmacist, they not only make mere agents of themselves, liable to lose their agency at any time, but they sap the foundation of retail pharmacy as a separate avocation, destroying its professional part and rendering its trade portion liable to be turned into other trade channels. Worse still, their action, or rather inaction, tends to deprive the public of that safeguard against the supply of bad drugs, which the Pharmacy Acts were designed to afford. This minor cause of pharmaceutical depression will become a major influence unless soon checked. Of course many medicinal preparations always have been and always will be made better and more economically in a large wholesale way than on a small retail scale. These are exceptions. But the majority of such things could be prepared as easily and often more cheaply, if with a little trouble, by the qualified chemist and druggist; and he has only himself to thank for the extent to which, through not taking trouble, or through not working professionally, he may have experienced loss of professional or commercial advantages. He must not blame wholesale dealers for prosecuting a variety of trade he has himself relinquished. Wholesale druggists considering that drugs must pass through their hands, no matter by what agency those drugs are distributed retail, would probably prefer their old and simple *rôle*, and supply drugs to retail druggists only. But if forced by circumstances to do the retail druggist's duty of packing drugs in retail sized parcels, and to sell them to non-pharmaceutical distributors, the wholesale druggists will, of course, do so with little hesitation. The mischief is that unqualified wholesale dealers may and do start up and perform such work. And we may predict that wholesale grocers and others, finding other dealers' travellers amongst their own shopkeeping customers, will themselves begin to deal in drugs. All of which is not to the advantage either of the public, the medical profession, wholesale druggists or retail druggists. "Drugs for the druggist" is a cry in which each of these four classes of the community, in their own best interests, may unhesitatingly concur. *Pace* haters of monopoly. For certain it is that competition in this over-populated country, and the jealousies and distrust of one another inherent in human nature, and not the least in pharmaceutical human nature, will always prevent the evils of monopoly making headway in pharmacy.

The general depression in trade, especially in agriculture, which has affected this country during the past few years, has of course affected pharmacy. Druggists do not complain of this. But with scarcely an exception, my correspondents state emphatically their opinion that the depression in pharmacy is far greater than in other callings. A want of prosperity, general to the country, is shared by pharmacy; but this is only one of the minor causes of pharmaceutical depression.

During these bad times, too, the proportion of medical men who dispense their own medicines has, I am assured by nearly all my correspondents in England, greatly increased. The reverse appears to obtain in Scotland. Indeed it appears that not unfrequently in consultation cases in which a physician is called in, at all events in the southern half of Great Britain, the prescription of the physician is intercepted by and dispensed by the medical practitioner. It would seem from this as if the old days of the apothecary of past centuries were coming round again. And from what I have previously stated respecting the increasing trade in drugs by grocers and others, it would seem as if the days of the drug grocer—the parent of the drug-gist, as the latter name implies—were after more than two centuries coming round again. This state of things would be, however, for Old England, not progression but retrogression, not advancement but degradation, not evolution but devolution. *Absit omen*! No, we hope and believe that this condition of pharmacy is only temporary. Besides, the medical man of the present day is one who, while having greater professional knowledge of medicine—that is of diagnosis and therapeutics—than the old apothecary, has less professional knowledge of pharmacy. As a pupil in medicine he has had too many other subjects to study, and as a practitioner he has too many other matters to occupy his attention, to allow of his possessing the old apothecary's acquaintance with pharmacy, and still less to allow of his having anything like the modern druggist's professional knowledge of pharmacy. And as regards the future, the increasing demands on him in matters, relating to the preservation of health, as well as to those which are ever increasing his power of dealing with disease, will still further remove from him opportunities of studying pharmacy. So that the selling of medicines and raw drugs by medical men, even if it could become sufficiently general, which is not in the least degree likely, would not relieve the public from the difficulties encountered in deserting the druggist. The point to which, however, attention is now more especially drawn, is that the tendency of the medical man to be his own druggist, decreasing up to about ten years ago, has, since that time, increased, and that this increase is one of the minor causes of the depression of pharmacy during the past decade.

Improved sanitation; a more extended knowledge of hygiene; less overcrowding; a more general realization of the importance of exercise for the body, and of mental and physical recreation generally; a more temperate use of our most seductive stimulating fluid and of those dishes which are nice but not nourishing; the employment of pure water for drinking purposes; a diminished superstitious belief in the therapeutical virtue of inert substances; in short, a better knowledge of the laws of life and of health, have combined to render medical practitioners and drugs and druggists less necessary to the world than they were sixty or seventy years ago. But do the members of the noble profession of medicine, including their half-professional, half-commercial brethren of the fourth estate in medicine, namely, pharmacy, complain of this advancement in knowledge? On the contrary, these very men and others like them—by their researches and discoveries freely communicated to the world through the machinery and periodical literature of the various medical, chemical, and pharmaceutical societies, conferences, and associations—these very men are those who have most largely contributed to this advancement in the wisdom and welfare of mankind, and none glory in it more than they do themselves.

But the labourer for the good of all is at least worthy of reasonable reward when working at his calling. The pharmacist will continue his researches for the well being of his fellow men. When, however, in Great Britain, the State says to him, "It is necessary that you who deal in drugs should for the welfare of the community be properly trained as an apprentice, be educated, be examined, and be registered," and then, when the druggist has willingly complied with the demand, the State permits untrained, uneducated, unexamined, and unregistered men to deal in drugs, the trained, educated, examined, and registered man rightly feels aggrieved and turns to the State for redress. Let this always be remembered, however, namely, that not only for himself does he seek the remedy. He reminds the State that it was for the protection of the public health that he was required to be educated, examined, and registered, and that it is in the interests of the public far more even than in his own interests that he asks that this protection be saved from being a sham, as well as that it be saved from being a mere handicapping arrangement preventing him from making his way in the race for a livelihood.

Does it never occur to the man who purchases cheap physic at a co-operative store, at a general dealer's, or some other shop, to wonder what disadvantages would result if everybody adopted that course. A very little reflection would suffice to picture a few. In the middle of a night, at a time of sudden and serious illness of one whose life is precious, he will require a certain trustworthy medicine. To possess it he would give ten times the total of the small sums he saved by abandoning his reliable druggist: for excruciating pain or perhaps something worse has to be combated without delay. He does not know at which grocer's or general storekeeper's he could procure the drug, and he questions whether such a vendor would leave a bed to inquire who is knocking at the door, even if the summons were heard at all; moreover, he is not certain he could trust the medicine obtained there. Then may come an all too late regret at the shortsightedness of the policy which ignored the professional skill and ever ready service of the qualified druggist in favour of the cheap but ignorant and unsympathizing general dealer. Again, a mother has been tempted to purchase paregoric elsewhere than of a druggist, not knowing that, unless the sale is an illegal one, the article is free from that opium to which, when present in proper proportion, much of the efficacy of the medicine is due. The compound being thus weak, she almost necessarily gets into the habit of giving considerably enlarged doses to her children. Some day there happens to be in the house, by accident, paregoric of proper official strength purchased of a chemist and druggist. The usual large dose is administered. Then, perhaps, all efforts to rouse her child from its deep sleep are unavailing. But to multiply illustrations where general facts are so palpable is unnecessary. I have already, in my opening remarks, shown why the supply of drugs, when uncontrolled by the State, is seriously prejudicial to the interests of the public. Eliminate special professional knowledge from pharmacy, and let drugs be sold by any or every shopkeeper, and the public will have no guarantee that they are not supplied with drugs fair in appearance to the untrained eye, but worthless to the trained eye of the druggist, drugs which once perhaps were of good quality, but which without altering in appearance have become spoilt by age, medicines weaker than they should be, medicines stronger than they should be, poisonous fluids for external application not properly distinguished from those for internal administration; indeed the public will have no guarantee that they are not supplied with the wrong medicine altogether.

To put the matter still more broadly. Every civilized state has adopted means for ensuring the supply to the public of trustworthy drugs by professionally educated druggists. Such almost universal action would not have been taken had it not been called forth by universal necessity. The necessity is at least as great in Britain as in any country. Indeed that necessity has been partially met even in this country by the enactments relating to pharmacy. But those Acts are working incompletely. The health and welfare of every individual in this land calls for a remedy for that incompleteness.

The nature of the remedy is simple. It has more than once been foreshadowed in the course of this address. It involves no new principle. It consists merely in an extension of the spirit and letter of the existing Pharmacy Act. Under that Act about a score of medicinal substances are deemed poisons within the meaning of the Act, and are to be sold retail, as a rule, only by registered chemists and druggists. *Let that list be considerably extended*, saving all rightful interests of persons who otherwise would be unfairly prejudiced. Let the retail sale in open shop of most of the simple and compound medicines of the British Pharmacopœia be carried on only by qualified druggists. Is the question asked, "Whence is to come the machinery for giving effect to such an extension? The present machinery under the Pharmacy Act is ample for the purpose—with perhaps a few improvements in matters of what may be termed pharmaceutical police, for giving better effect to certain sections of the Act, as for instance the employment of the inspectors under the Food and Drugs Act, or other inspectors, to see that unqualified traders do not infringe the Pharmacy Acts. In sparsely populated districts let drugs be sold by unregistered persons: these acting, however, only as agents, the drugs being contained in duly secured packages bearing the name and address of a registered chemist and druggist who should be responsible for the character of the contents. The parcels post has removed most of the transit difficulties connected with such an arrangement.

But it is no part of my duty in this address to enter further on the political details of practical pharmaceutical legislation. I desire to supply the materials of politics rather than to discuss politics. I have gathered together and furnished information, and have submitted arguments that should satisfy every Englishmen that there is a serious breach in the established relationship of the State to one important branch of medicine by which the health and welfare of the State is maintained, that is, to pharmacy. I commend that information and those arguments for serious consideration by members of Parliament, by the press, and by the public. For myself, I have no manner of doubt that could the attention of every thinking man in this nation be gained for one short hour to this present relationship of the State to pharmacy, he would vote for its reform in the direction now advocated.

At the conclusion of the address,—

Mr. Kershaw (Southport) moved a vote of thanks to the President for his address, which all would agree was a very thoughtful and suggestive one, handling very cleverly a most difficult subject. The first thought which occurred to him was that he should much like it to be put into the hands of every member of Parliament, because if they were to go in for further legislation there were certain facts there stated which ought to be thoroughly pondered. Probably the best mode of showing their thanks would be to give the address full consideration and deep study. They had been reminded of what pharmacy had been, what it was now, and what it could be. There was no doubt they had fallen on evil times, when pharmacy was passing through a transition period, and things were coming to a crisis. The Act of 1868, though well intentioned, had not done what it ought; it provided for an educated class, but what it intended beyond that remained still to be done. The end to be aimed at was that the public should receive their drugs through that educated class only. The first thing necessary to the cure of any disorder was a correct diagnosis, and that the President had given them; there might be different views as to how the cure was to be attempted, but in his opinion the only course was that pointed out in the address, viz., to amend the Pharmacy Act, by enlarging the scope of the word "poison," and extending the limits of the schedule. All drugs were poisons if unskilfully used. The abuse of hospitals and dispensaries had been referred to, and there was no doubt that many of the persons who received relief from those institutions were not of the class intended to be benefited. Chemists might perhaps agitate for an improvement in that direction, and ask that out-patients should not receive medicines at dispensaries, but only prescriptions to be dispensed by chemists in the neighbourhood.

Mr. SYKES (Southport) seconded the motion. He thought the address had treated a difficult subject in a most masterly manner, though it had shown pharmacy to be in a more depressed state in some places than he had expected to hear. He hoped the subject would be seriously taken up by all the members.

Mr. MOSS (London) desired to add a word in support of the motion. There was great difficulty in criticizing such an address, the materials having been so lavishly collected and presented that it was not easy to pick out any one point for special remark. A number of facts had been brought together for the first time, and so marshalled, that it appeared as if the position taken up must be impregnable to any attack from the outside. When it came to be considered thoughtfully and quietly, as he hoped it would be by all, they might hope that it might be fruitful of suggestion, and that some plan of action might be determined upon which would remove the wheels of the chariot of pharmacy from the rut in which at present they seemed to be imbedded.

Mr. ATKINS (Salisbury) remarked that the present address formed a very fitting pendant, giving the other side of the shield, to that presented last year at Southampton. The President then dealt with the trinity of the collection, preparation, and distribution of drugs and chemicals; to-day he had dealt with the relation of the State to pharmacy on one particular point, viz., distribution. He felt that the President had painted the picture in the most sombre tints; he would not say that they were unduly sombre; indeed, in the face of such facts as had been cited, it was difficult to contend that the picture was otherwise than correct; but remembering that the darkest hour of night was nearest the dawn, they would hope for better things before long. At the same time he believed that some portions of the difficulty were irremediable in themselves. As the President had pointed out, there was an increased knowledge of sanitation on the part of the public, and a decrease in the quantity of drugs administered, and, as his own experience would bear out, another important fact was the large amount of eleemosynary administration of medicine. It was obvious, therefore, that there were many facts to be faced, over which they had no power. There were, however, remedies which might be applied, and, as they were aware, the Council of the Pharmaceutical Society had for some time been at work on an amended Pharmacy Act. It was no longer a question of free trade, but of lawful and justifiable protection. The State wisely demanded education, qualification, examination and registration, and having done that, those who, having complied with the demand, asked for a fair share of protection were thoroughly warranted in doing so. They might say to the State, "If you will have free trade, have it all round; but if you demand from us education and skill to dispense wisely, then we ask for some professional protection." He was very glad that a man so eminent as the President had taken up this subject, which, if treated by smaller men, might have led to invidious remark. The *res angusta domi* could not be lost sight of, and he was very grateful to the President for what he had said.

Mr. SAVAGE (Brighton) said there was little to say after the exhaustive address of the President, except to consider the difficulties to be contended with in connection with legislation. Most of them knew that amongst members of Parliament were the warmest supporters of the co-operative store movement. Their own registered members were not perhaps altogether free from blame in this matter, but they were sometimes placed in a very difficult position. If there were a co-operative store in the immediate neighbourhood it was very difficult to tell a customer a price was 1*s.* 1½*d.* for something he could get for 9*d.* or 10*d.* It appeared to him that the only way in which legislation could be effected was for every pharmacist, each in his own locality to endeavour to influence his own representative. In some large towns medical men were adopting a course which must be very detrimental to chemists, for he had seen notices exhibited "Medicine and professional advice, 6*d.*; if the patient is visited at his own house, 1*s.*" What could a chemist do against that? He knew a case of two brothers, one of whom kept a co-operative store, and the other advertised that if anyone ordered drugs to the extent of £1 he would allow 5 per cent. off the store prices.

Dr. QUINLAN (Dublin) said he might say a word as to the way in which pharmacy was conducted in Ireland. At the beginning of this year the Government addressed a communication to the professors of Kings and Queen's Colleges, asking them to send in suggestions for an amended schedule to the Pharmacy Act. A Committee, of which he was a member, was appointed to deal with the matter and a list was sent in containing a number of things which were poisons of the most deadly character; but in reply a letter was received from the Under Secretary saying that the addition of these things to the schedule would interfere with the course of trade and manufactures. The reply of the Committee was that dangerous articles ought to be sold only by men who knew what they were selling, and who could advise their customers upon them; and the Committee insisted on the schedule, but was not able to carry it. His experience was that in Ireland anybody sold medicines who liked, but they did not, as yet, compound medicines, and the co-operative stores did not compound prescriptions; in fact with regard to medicines the Irish public seemed to prefer the apothecary or pharmaceutical chemist, perhaps because the co-operative stores had no right to sell and did not open on Sundays. With regard to hospitals and dispensaries, if time permitted, he could say a great deal. He had seen a nurse come to a hospital, and when asked where she lived, she gave the address of a man who was certainly worth a thousand a year. He had seen a patient brought to a hospital in a brougham, the property of the family; in fact, he could easily occupy half an hour with tales of the way in which the physician, apothecary and chemist were robbed. There was a great deal in what had been said about the reduction in the quantity of drugs taken; the days of drugging and drenching were over, and physicians did not use more than one-third the quantity of drugs they did formerly. A great deal of mischief was done also by the sale of ready made pills, which were sent out with little treatises accompanying them, stating they would cure almost anything, and he feared that some of his brethren did a great deal of harm by prescribing these things. The public would soon learn to get them for themselves and prescribe them for their friends, and would forget to call and pay a fee to the doctor, who originally recommended them. He quite agreed with the President that the chemist was a professional man and he had so described him in one of his papers. It was impossible for a man to practise as a pharmaceutical chemist without having had a good general education to begin with, and a special technical education superadded to it, and it was absurd to esteem such a man as a mere retail tradesman, or to suppose he was to receive only 5 or 10 per cent. on the price of his wares.

Mr. Young (Edinburgh) said it was not usual to criticize an address of this kind, but he could not sit still without expressing his approbation of all that had been said as to the condition in which pharmacy stood at present. It appeared that Scotland had suffered less from the changes which had taken place during the last ten years, than other localities; whether that arose from the Scotch habit of self-reliance, he did not know, but his own experience was that they were no worse off than before. This might arise in some measure from the increased education medical men received, which induced them to hand over their dispensing to a chemist. He thought the time was come when something should be done in the direction the President had indicated, if it could be done so as to include a larger number of drugs in the schedule. At the same time the present was an age when free trade had such a hold of the public mind that there would be great difficulty in obtaining what they required. It would depend very much on the manner in which pharmacists stood shoulder to shoulder, and endeavoured to impress the public and members of Parliament with the fact that they did not seek their own advantage only, but the welfare of the public.

Mr. Frazer (Glasgow) said that if he did not accept all the views enunciated, he could still thank the gentleman who had put them forward so clearly. Professor Attfield, with his usual clearness, had put forward his view of a very difficult question, and those who differed from him totally on this question would be glad to have before them the very clearest and fullest exposition of those views.

Dr. Symes (Liverpool) also desired to thank the President for the able manner in which he had collected so many facts bearing on the question, though he could not altogether agree with all the deductions drawn from them. His experience was that the public took more medicine than they used to; and it was now much more the custom than it used to be to call in a physician for little ailments in a family. Altogether, he felt very thankful to the President for the facts he had collected, but he hoped the case was not so bad but that with a little earnest effort it might be set right.

Mr. Schacht (Vice-President), in putting the motion to the meeting, said that his only regret was that this able and complete address, appealing to the inner sense of right and justice in every man, was addressed almost exclusively to pharmacists. They must, however, all do their utmost to let the public, *oi polloi*, the great mass of the community, understand the position, for it was from them and them alone that they could hope for any effective pressure on the Legislature. If the only remedy lay in the direction of improved legislation, they could only hope to obtain it by pressure from below. He had the greatest confidence in the good sense of the public at large, but on special subjects that good sense required to be instructed.

The motion was then put and carried by acclamation.

The President, in reply, said he was about to apologize and explain to the many eminent pharmacists present and those with whom he had been associated for many years, why he had ventured to address them on these social and political relationships of pharmacy, with which they were so much more familiar than he was, viz., that he had deliberately decided on being so obtrusive because of his conviction that these relationships would be better and more usefully put before the public by one occupying his position, than they would be by a practising pharmacist. But all these apologies and explanations were rendered unnecessary by the kind manner in which the address had been received, and he could only thank the members most heartily for the way in which the vote of thanks had been carried.

The Conference then adjourned to luncheon.

(*To be continued.*)

OPINIONS OF THE PRESS UPON THE SUBJECT OF PROFESSOR ATTFIELD'S ADDRESS.

From the *Times.*

"We report to-day an interesting address, delivered at Southport to the Annual Pharmaceutical Conference by its President, Professor Attfield, from which it appears that the conditions upon which the purity of medicines depends are at present placed in no small jeopardy. Several years ago the attention of some of the leading retail druggists of this country was directed to the evils which were then constantly arising from the imperfect knowledge of many of those who were engaged in selling drugs and in dispensing prescriptions; and hence these leading druggists formed themselves into a society, the Pharmaceutical Society, which had for its object to raise the standard of acquirement among members of the trade. Examinations were instituted, and were voluntarily passed by numbers of intending chemists, with the result that the Society was ultimately incorporated by Royal Charter, and that an Act was passed compelling all persons who wished to become chemists and druggists to undergo examination before they were permitted to engage in the calling. The position of the druggist was, in short, assimilated to that of a member of the legal or medical profession; and on the same general ground—namely, that the chemist deals in commodities of the quality of which the purchaser cannot possibly judge, and that it is therefore expedient for him to be protected by some guarantee of knowledge on the part of the seller. The Act came into operation, and for a time all went well. At last, however, it seems to have occurred to some ingenious person that, although it was necessary to pass an examination before assuming the title of 'chemist and druggist,' it was quite easy to carry on the business without assuming the title. In consequence of this discovery, many members of other trades sought to increase their earnings by combining the sale of drugs with that of other commodities. The druggist had been accustomed to charge for his wares at a rate which afforded him not only a return for his capital, but also a reward for his special skill and knowledge; while his opponents, who had neither skill nor knowledge, did not pretend to charge for them, and were content with a profit on capital alone. The effect was that the legitimate druggists were greatly undersold by these new competitors, and hence that the general prosperity of the trade has been steadily declining for some years past. Professor Attfield maintains, and it would be very difficult to dispute his conclusion, that the public have a distinct interest in arresting this decline of prosperity, and in enabling chemists to carry on their business upon reputable and profitable terms.

"The manner in which, as it is asserted, retail chemists are being pushed out of existence forms part, it need hardly be said, of the revolt against excessive retail profits which has of late years become general among people of moderate income. Professor Attfield might possibly not condemn this revolt as a whole; but he contends very forcibly that it is misdirected in the particular case with which he deals. It is manifestly true that many shopkeepers in small business struggle through life with great difficulty, but their hardships make no impression upon the public. The impression is made by the retail trader in full swing, who occupies a shop in a leading thoroughfare of some great city, and who appears to receive an income in excess of the value of the services which he renders to the public. Producing nothing, and often depending upon the taste and skill of salaried buyers for the selection of the stock on which his profits are made, he stands as an intermediary between the producer and the consumer, and levies a toll for which there seems to be no adequate justification. It would not be easy to blame him for demanding whatever prices he finds it possible to obtain; but, on the other hand, no one can blame his customers if they scrutinize his profits with some closeness, or even if they eventually take measures to diminish their own contributions to them. There are some trades, however, in which the action of the intermediary is extremely valuable, and of these that of the druggist is a conspicuous example. It is of the highest importance to all who require medicines that they should be of good quality, neither impaired by keeping nor defective by reason of faulty preparation; and yet in the whole range of articles of merchandise there can be few which are liable to so much designed or accidental variation. Many drugs are parts of plants, leaves, roots, bark, and the like, and the qualities of these will vary with soil, season, and manner of collection, besides being prone to deteriorate by lapse of time. Many others are chemical preparations which may be injuriously affected by careless manufacture; and all alike are seriously exposed to risk from that all-pervading practice of adulteration which is described by a well-known politician as a legitimate form of commercial enterprise. In order to sell any named drug with safety and propriety the seller must be thoroughly acquainted with its appearance and other peculiarities, must know how to distinguish the genuine from fraudulent imitations, and, in a word, must be capable of maintaining a check upon the wholesale dealer from whom he draws his supplies. Such work as this is not mere distribution, mere buying in bulk to sell in detail; and it deserves to be recognized and paid for as something which possesses a higher value. It may be to the interest of the public to pay for it even at a considerable rate, for the sake of having such special information always available in time of need.

"Professor Attfield maintains, therefore, that the Legislature, which has already enacted that any one calling himself a chemist and druggist shall give a guarantee of the possession of certain knowledge, should further enact that no one shall carry on the business of a chemist and druggist without calling himself so—that is to say, that only recognized and duly qualified pharmaceutical chemists shall be allowed to sell active medical preparations. He would meet the case of thinly-peopled districts, in which a chemist might not be able to find a living, by permitting other tradesmen to sell medicinal articles of common consumption in closed packets, put up under a chemist's guarantee; and there can be little doubt that some legislation on these lines is really required. Professor Attfield, as the result of extensive inquiries, pronounces chemists to be in a state of declining prosperity; and it is dangerous to the public that a chemist should be put in the position of Romeo's apothecary and should be tempted, if not to vend poisons in an unauthorized manner, yet to sell inert or adulterated drugs for the sake of a trifling addition to his scanty gains. The persons who call themselves 'wholesale' druggists, and upon whom there is no check of any kind save the knowledge of the retailer, are often very accommodating in their range of prices, and are prepared to furnish a powder or liquid of respectable appearance, called by some given name, for perhaps a sixth part of what it would cost if genuine. The grocer who deals in drugs, but who has no knowledge of them, may sell adulterated or useless stuff quite innocently, if, indeed, it be innocent for him to engage in the business at all. The value of the educated druggist is, or ought to be, that he protects the consumer, and for affording this protection he has a clear right to be paid. Professor Attfield suggests that the chemist might avowedly justify his charges by his knowledge of the things in which he deals; that he might say, in effect, 'this medicine which I sell for sixpence cost me only twopence; and if I were a grocer, I could sell it for threepence and be content. The remaining threepence is not my charge for the medicine, but for my time and trouble in ascertaining that it is genuine and unimpaired.' We think the consumer would generally admit the plea; and hence that, on the ground of special knowledge, the druggist might fairly hope to triumph over any unreasoning desire for cheapness which co-operative stores, or kindred institutions, by giving it where it can be rightly given, have perhaps fostered in conditions which prevent it from being conceded without risk to the public. When Parliament meets, we trust that the official representatives of the drug trade may be able to obtain a serious consideration of the existing state of things, and that some measure for rendering the Pharmacy Act no longer a dead letter may before long find its way into the Statute-book."

From the *Daily News.*

"Professor Attfield's address to the British Pharmaceutical Conference on Tuesday, though in a manner an address devoted to a single trading or semi-professional body, was one of considerable interest and importance to the public at large. That public is wont, from a kind of instinct, to be rather sceptical of jeremiads as to the state of particular trades and professions, and without flippancy Professor Attfield's address may be said to be something of a jeremiad. It deplores the irregular competition to which regularly qualified chemists and druggists are exposed, and it demonstrates—not insufficiently—that 'pharmacy is not what it used to be.' We have said that there is a certain tendency in the outside public to take such demonstrations as this somewhat coolly. It is felt that if a certain trade or profession is exceedingly flourishing the public may make up its mind that it is flourishing at somebody's expense, and that that somebody is probably the public itself. Professor Attfield, however, has shown very conclusively that the entire disestablishment of the qualified chemist and druggist would be a public misfortune, against which the possibility of obtaining a shilling bottle for ninepence halfpenny will not be set by any wise person. It is, moreover, quite evident that it is, as he contends, an absurdity to maintain a solemn Act on the Statute-book inflicting pains and penalties on Dick, Tom, or Harry for calling himself a chemist and druggist without qualification, while any Harry, Tom, or Dick is at liberty to keep a chemist and druggist's shop, and to sell chemicals and drugs with no more qualification, licence, or State recognition of his fitness than his neighbours the bookseller and the draper.

"Professor Attfield has a double line of attack. He argues that it is unfair to impose the tax of a certain education and preparation on the qualified druggist, while the unqualified drug-seller carries on, unhandicapped and unhampered by any such preliminary expense, a competitive trade in almost every, if not in every, article of which the State licensee is supposed to have given the qualified person the monopoly. But foreseeing the obvious answer to this argument—that legislation is not intended to keep up a profitable monopoly, but to secure the public interest—he argues further, that the public are not and cannot be as well served by these mere distributors as by professional pharmacists. Of the fact, as distinguished from the inference, of the first part of the argument there can be no doubt whatever. In London, at least in its wealthier quarters, the competition with the chemist and druggist proper is chiefly limited to the co-operative societies and to the large private stores and "universal providing" shops. But in the country it is certainly common enough to find shopkeepers of almost every trade keeping and vending all the commoner as well as many of the less common simples and compounds of the pharmacopœia. And it may be further allowed that there is force in Professor Attfield's argument that drugs, especially compounded drugs, are not properly or safely to be made the subject of unskilled distribution, that much depends on their quality or condition which cannot be left to a mere distributor to decide upon, and that in estimating druggists' charges allowance ought to be made for the fact that a man of some education and practical skill is practically putting his services at any hour of the day or night at the disposal of the neighbourhood where he sojourns. It would certainly be a forlorn hope to attempt to knock a co-operative society out of its bed at midnight to furnish the antidote or the restorative required to save life; and even the most affectionate of relatives might hesitate to call in the services of an obliging haberdasher to make up a prescription with half-a-dozen—even mild—poisons in it.

"So much will generally be granted, and the anomaly of the present Pharmacy Act may be freely recognized. But it must be questioned whether it is in the power, and still more strongly questioned whether it is within the proper province, of legislation to apply itself directly to the remedy of the state of things of which Professor Attfield complains. That state of things is due to a variety of causes by no means all of which are recognized by the Professor. In the first place, all his ingenious fencing about the charge of the regular chemist being rather a professional fee than a trade price does not parry the accusation that this charge is but too generally an exorbitant one. A certain person who, being in bad health and having to travel about much, had occasion to make constant use of a particular medicine, once had the curiosity to compare the charges of different regular chemists for it. He found that for the same supply made up from the same prescription, the charge varied from one shilling to half-a-crown, and he had the curiosity to ascertain that the prime cost was something under sixpence at retail prices for all the ingredients, the bottle, and so forth. Now it is not in drug selling only that profits of from 100 to 400 per cent. have become things of the past. Again, the chemist complains of competition, but are all the articles or even the most profitable articles of his trade strictly drugs? Does he not deal largely in perfumes, soap, mineral and aërated, but not medicinal, waters, miscellaneous toilet wares, knick-knacks of all sorts and kinds? If he throws stones at the grocer and the bookseller, may not the perfumer, the oilman, the brushmaker, the liquor seller retort on him? And with regard to the really important question of dispensing proper, are not chemists themselves liable to the charge of overstocking the market? The falling off of registered druggists which Professor Attfield mentions may not be such a great disadvantage to the trade, and it might probably, at least in large towns continue still further without any district being deprived of a qualified dispenser within easy distance. Many people must have wondered what chemists find to live upon in the suburbs of London, considering their number. The fact is that, partly from the supposed inheritance of the old apothecary status, partly from the custom of equipping the shop expensively and showily, the druggists trade has long held the position of a 'genteel business.' All genteel businesses tend to be overstocked, and it may be added that they are especially liable to dangerous competition from persons who have a keener eye to business than to gentility. Further, all distributive trade tends nowadays towards concentration, towards the cutting down of profits, and towards the substitution in large measure of comparatively unskilled labour for skilled labour. This last is to be regretted, though it is an almost inevitable result of increased population, of machinery, and of the effect of both on wages. But despite Professor Attfield's facts, we entertain very great doubts whether the duly qualified druggist is as yet scarce or likely to be scarce in any populous neighbourhood. If it became really difficult to find him, legislative efforts for his preservation would have to be made no doubt. But the Professor will hardly strengthen his case by putting in, as he does, a plea for allowing chemists to practise what is called 'counter prescribing.' In the first place a complaint of competition with the chemist in drug selling is but awkwardly mated with a recommendation of competition by the chemist in drug-prescribing. In the second we venture to think that the harm done by this amateur doctoring considerably exceeds that done by the selling of inferior, adulterated, or spoilt drugs owing to the incompetence of the seller. In short, it is possible to go with Professor Attfield so far as to allow the justice and advantage of drawing the line of outward and visible difference between the qualified and unqualified drug vendor somewhat more broadly and distinctly than is done by the Act of 1868. It may also be granted him, though not to the extent which he seems to desire that the list of drugs and compounds which none but a duly qualified person may sell on any terms might be advantageously enlarged so as to draw such a line. But the principle of any such extension must be not the protection of the chemist in the one sense, but the protection of the public in the other."

From the *Standard*.

"The address which Professor Attfield delivered on Tuesday to the Pharmaceutical Conference, while serving as a sort of 'side show' to the British Association, which is also in session in Southport, would scarcely have deserved even the much abused name of 'science.' Nor do we imagine that any such rank is claimed for it. The meeting over which Dr. Attfield presides is to a certain extent a great trade union, and his discourse touches mainly on the extent to which grocers who sell drugs physicians who prescribe proprietary articles, patients who decline to swallow physic, and general practitioners who dispense their own medicines are cutting into the business of properly qualified druggists.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Parke, Davis and Co., Swadling, King, Dewson, Umney, Haydon, Smith, Sawer, W. H. P., M. P. S., X. Y. Z., Associate.

"THE MONTH."

Falling leaves and autumnal tints indicate that the reign of flowers is nearly over for this year. The scarlet berries of the dulcamara and the purple fruits of the belladonna and the thorny "apples" of the stramonium show that fruits have taken the place of flowers, and those who are now about to commence their botanical studies will do well to make the most of the flowers still left for examination.

At the Royal Gardens at Kew the scammony is still in bloom. Wormwood, borage, *Lobelia syphilitica*, *Saponaria officinalis*, and *Nicotiana Tabacum*, afford an opportunity of studying the characters of the natural orders to which they belong. The fruit of the dog-rose, buckthorn, hop, fig, squirting cucumber, and many others are now in good condition for forming a practical acquaintance with their structure. The beautiful coral-like fruits of the spindle tree, *Euonymus Europæus*, should not be overlooked, affording as it does an example of the arillus.

The *Euryale ferox* has recently blossomed at Kew. The large leaves, often nearly 3 feet across, purple and spiny beneath, and also furnished with spines on the upper surface, vie with those of the *Victoria regia*, in flower at the same time. The seeds of this plant usually occur in collections of Hindoo and Chinese materia medica, being thought to possess medicinal virtues. In Bengal, however, the seeds after being baked in sand are eaten by the natives.

The *Cassia Tora* is also now in flower in the Economic House. This species bears some resemblance to fenugreek in the leaves and narrow pods, the latter of which are very different in shape from most of the other species of the genus. The leaves have a reputation in India as a cure for ringworm.

An interesting note, by Mr. W. B. Hemsley, appears in the *Gardeners' Chronicle*, in which he gives an account of the opinions held concerning the variety of the wild raspberry named var. *Leesii*. The general consensus of opinion appear to be that it is a hybrid between the strawberry and the raspberry, although this has not been proved as yet by direct experiment.

The subject of the continuity of protoplasm by means of delicate threads through the walls of vegetable cells attracted considerable attention at the meeting of the Biological Section of the British Association, at Southport. Mr. W. Gardiner, who has examined fifty species of plants and found this continuity of protoplasm in all of them, pointed out that this fact places us in a position to obtain a clearer insight into such phenomena as the downward movement of a sensitive leaf upon stimulation, the influence of a germinating embryo upon the endosperm cells, and of the action of a tendril towards its support. Professor Hillhouse suggested that the protoplasmic threads may serve to transmit impulses from one cell to another and thus act somewhat like a nervous system. Dr. Carpenter remarked that there are forms in the animal kingdom in which the cell is never arrived at, but in which there is simply a continuity of protoplasm, so that the lower forms of the animal and vegetable kingdoms are here closely approximated to one another.

Mr. C. A. Macmunn read a paper on the occurrence of chlorophyll in animals. He stated that he had found this green colouring matter in the intestines of invertebrate animals, and had arrived at the conclusion that the chlorophyll found in animals not only has all the characteristic appearances of vegetable chlorophyll, but is synthetically built up by and in the bodies of animals. Professor Lankester confirmed the views of Mr. Macmunn, remarking that the idea held by some, that the chlorophyll found in animals is due to minute parasitic algæ, was opposed by the consideration that chlorophyll has been found in a diffused condition throughout all the tissues, and not merely in the form of little globules which might be considered as independent organisms. The attempt to draw a line of demarcation between the lower forms of the animal and vegetable kingdoms is therefore becoming gradually more difficult.

Some valuable and pertinent remarks occur in the *Gardeners' Chronicle* (p. 208), concerning prizes given for collections of plants and flowers. The editor remarks that any procedure which might lead to the extermination of a rare plant should be discouraged, such as giving weight to the rarity of a plant in the awarding of a prize. He suggests also that prizes might be given for collections of plants from different geological formations, or of maritime plants, etc. "To offer prizes for the largest and best named collection of wild flowers is not to advance botany, *i.e.*, a knowledge of plants . . . It encourages mere collectors, many of whom know nothing of plants beyond their names." This is quite true, and is induced by the nature of the competition. Every spare moment of time is naturally devoted to adding to the number of plants, so as to increase the chances of winning the prize, and the names are naturally obtained in the easiest way possible, often by comparison with illustrations instead of by careful analysis of the flowers. A prize offered for the best dissection and descriptions of a small number of plants, or for a collection of the forms and varieties of a few polymorphous species, would do far more to cultivate a habit of careful observation and systematic work, as well as an accurate knowledge of plants.

The *Gardeners' Chronicle* (p. 237) gives an illustration of a gigantic equisetum (*E. giganteum*) which was seen by M. André growing to a height of 16 feet at the base of the volcano Corazon, near San Florencio, in Equatorial America. The plant grows in marshy ground where the water surges up at every step. Its appearance reminded the celebrated traveller of the immense Lepidodendrons and Calamites, to whose decay we owe our coalfields.

The cultivation of the *Eucalyptus* has of late become extended greatly in the province of Malaga, in order to supply the constant demand for charcoal caused by the excessive use of the fuel for cooking purposes. The tree is also used to form avenues in the neighbourhood of the city. Some low districts which were formerly uninhabitable, owing to malaria, are reported to have been considerably improved in consequence. The extensive cultivation of the plant should lead to the production of the essential oil at a comparatively low price, and to fresh uses being discovered for it.

In some notes in the *Garden* (Sept. 8, p. 212), by Mr. Geo. Nicholson, of Kew, on the genus *Sophora*, it is mentioned that this tree possesses cathartic properties, and that "in the Botanical Garden of Dijon is a well beneath a fine *Sophora Japonica*, which the gardener is obliged to cover over when the leaves or flowers are about to fall," having found by experience that the water acquires laxative properties through the sophora being infused in it. The active principle examined by M. Fleurot, of Dijon, proved to be a non-crystalline substance analogous to the cathartin of senna leaves. Another species, *Sophora angustifolia*, is said to yield the intensely bitter root used in medicine in Japan, under the name of "kus-ham" or "kiusiu," in which M. Petit recently discovered a new alkaloid.

A writer in the *Gardeners' Chronicle* having drawn attention to the danger of honey being rendered poisonous by the visits of bees to the flowers of the aconites so commonly cultivated in gardens, it has since been pointed out that the hive bee does not commonly collect honey from these flowers, presumably because its tongue (proboscis) is too short to reach it, so that humble bees are most frequently seen upon them (*Gardeners' Chronicle*, Sept. 8, p. 289). The golden rod and wild aster have recently been recommended by the Rev. L. L. Langstroth, the inventor of the movable frame-hive, as suitable for planting in waste places near beehives. He states that bees will forsake almost everything else for them (*Gardeners' Chronicle*, Sept. 8, p. 306).

Stings by wasps and bees although generally not very dangerous do sometimes produce alarming symptoms. In a case related in the *Lancet*, Sept. 22 (p. 528), in which great nervous excitement, prodigious swelling and delirium were produced by the sting of a bee, Dr. T. Harrold found the administration of 15 grains of sulphocarbolate of sodium in an ounce of water every four hours rapidly diminished the symptoms after the second dose, caused a profuse perspiration and resulted in the convalescence of the patient. One of the simplest remedies, and one which can quickly be applied in the case of stings of insects, is to press the tube of a key firmly over the place stung; this prevents the immediate absorption of the poison and presses the sting out when it has been left in the flesh.

With respect to the paragraph in the Month (before, p. 62) relating to the use of "crotalus" in scarlet fever, a letter has been received from Dr. Hayward stating that for subcutaneous injection "it is three to five drops of the first centesimal (1 in 1000), not the first decimal attenuation," that is used. Further, it is not the poison bag that is taken, but the "pure venom itself, pressed out by the finger and thumb through the fang into a small bottle, and there immediately mixed with [nine parts of] pure glycerine."

According to Dr. Bonatti (*Glasg. Med. J.*, xx., 239) chloral in infusion of senna acts as a safe, prompt, powerfully drastic, and easily administered aperient in cases of obstinate constipation such as are often met with in the treatment of the insane. He gives it in doses of one, two, or even three grams of chloral hydrate in one hundred grams of infusion, with thirty grams of syrup added.

According to Messrs. Gehe the demand for convallamarin and lily of the valley flowers has considerably abated. This rapid abandonment of a new remedy might find another explanation than the passing away of a nine days' wonder, if *Punch* shadows forth the truth in the following conversation: "*First Country Doctor*: 'Could you come to my place, Brown, to-morrow morning?' *Second C. D.*: 'All right, old man. What is it?' *First C. D.*: 'Well, I've had a case of endocarditis which I've very successfully treated with *Convallaria majalis*, and I want your help with the *post mortem*.'"

Dr. H. P. Powell, of Cleveland, Ohio, has directed attention to the advantages of the administration of chloroform to children during sleep. The little ones are saved from fright and its effects, and from the excitement which the administration frequently causes, and operations can be successively performed during sleep (*Brit. Med. Journ.*, Sept. 15, p. 555).

At a meeting of the New York Medical and Surgical Society (*Practitioner*, September, p. 212), Dr. Flint gave the results of the trial of oil of wintergreen in rheumatism. In thirteen cases tried at the Bellevue Hospital it had yielded rather better results than those ordinarily obtained with salicylic acid. The oil was given in 10-drop doses in linseed tea several times a day. Dr. Kinnicutt also stated that he had used the oil in acute rheumatism with good results, and had found that it was less disagreeable when administered in milk than either salicylic acid or salicylate of sodium.

Some interesting researches upon the probable mode of action of "antiseptics" employed in the dressing of wounds have occupied the attention of M. Gosselin, who has worked with solutions of carbolic acid varying in strength from 1 to 5 per cent., alcohol and dilute alcohol and camphorated spirit, applying the solutions to transparent animal membrane through which the capillary circulation could be observed. He reports (*Comptes Rendus*, xcvii., 541) that upon contact of the antiseptic with the membrane the circulation of the blood in the capillaries is arrested, more or less quickly in direct proportion to the strength of the solution. This arrest he thinks can only be attributed to coagulation of the blood determined by contact with the medicament after it has traversed the very delicate membrane to which it has been applied and the still more delicate walls of the capillary vessels. M. Gosselin points out the analogy of this action to that of caustics and expresses an opinion that as far as it goes it is a true causticizing one. It would appear, therefore, that these medicaments act first as germicides or antiseptics and then as astringents and semi-caustics. In view of the fact that carbolic acid has been reported to have exercised a toxic action when applied to a wound it may be remarked that if coagulation really does follow the application of such solutions in proportion to their strength it is possible that a weak solution would in some cases be more likely to exercise a poisonous action than a strong one.

Freshly dried sphagnum moss has recently been recommended by Dr. Hagedorn, of Magdeburg (*Med. Times and Gaz.*, Sept. 1, p. 246), as a cheap, very absorbent, elastic and conveniently applied dressing for wounds. It is used in conjunction with a weak solution of sublimate.

The use of plastic clay as a convenient material for suppositories in some cases is recommended by Dr. Trippier (*L'Union Pharm.*, xxiv., 398). The ordinary sculptors' modelling clay is used, the medicaments being dissolved in water and then worked into the mass; in this way salts of iron and copper, alum or even vegetable extracts may be incorporated by taking proper precautions. Dr. Trippier appears to contemplate supplying patients with the medicated clay, so that they can break off a portion and mould it between the fingers as required. Although the mass may easily be maintained of a proper consistence in a vessel placed in a plate containing water and covered by a bell-glass, it is liable to harden if exposed in the open air; but this may be prevented by the use of glycerine, which is said to have the additional advantage of giving stability to a potassium iodide mixture. The formula given for such a mass is—clay, 500 grams; water, 50 grams; potassium iodide, 30 grams; glycerine, 100 grams.

The physiological action of cotoin and paracotoin has been the subject of an investigation undertaken by Dr. Albertoni (*Archiv. exp. Path. u. Pharm.*, xvii., 291), with a view of thowing light upon the nature of the effect produced when these substances are administered in cases of diarrhœa. It was found that cotoin exercises no influence upon the process of digestion; neither does it prevent, but simply retards the development of bacteria. Its specific action seems to be to produce an active dilation of the intestinal blood vessels which promotes the nutrition and recuperation of the mucous membrane of the intestines and favours resorption. Paracotoin was found to resemble cotoin in its action, but to be less active. Dr. Albertoni recommends the administration of cotoin in powder enclosed in a wafer, or as an emulsion. He also gives a form for a solution:—cotoin, 0·40; sodium bicarbonate, 1·0; water, 100; glycerine, 20; dissolve with heat. The solution is said to be nearly, but not quite, perfect. According to a statement in Messrs. Gehe's circular, cotoin is coming steadily into demand on the Continent, but United States orders favour paracotoin.

Further experiments undertaken by MM. Cornill and Berlioz with a view to determine the general action on the body of the microbes found in an infusion of jequirity, *Abrus precatorius*, have led them to the conclusion that these bacteria are the sole active principle in producing the medicinal effects of the seeds. The infusion deprived of the bacteria by filtration after M. Gautiers' process produced no pathological effects, while the subcutaneous injection of a solution of the crystallized principle, prepared by M. Chapoteau from the seeds, produced no appreciable effects (*Comptes Rendus*, xcvii., p. 679).

The common southernwood (*Artemisia Abrotanum*) is reported by M. Craveri (*L'Union Pharm.*, xxiv., 410), to yield a crystallizable alkaloid, which he has named "abrotine." The sulphate, hydrochlorate and citrate have been prepared, all of which crystallize well, and the hydrochlorate is very soluble in water. Some preliminary physiological experiments with abrotine have been made by Dr. P. Giacova, who finds it to lower the temperature of the body, and to stop the action of a frog's heart in a few minutes. The alkaloid and its salts appear also to possess the property of preventing the putrefaction of albuminoid matter.

A West African bark, called "doundaké," used by the natives of the Rio Nunez as a febrifuge, has recently been examined by MM. Bochefontaine, B. Féris and Marcas (*Comptes Rendus*, xcvii., p. 272). The bark is of a reddish-orange colour and is formed of superimposed lamellæ, which are easily detached from one another. The taste is strongly bitter. The plant yielding the bark is a shrub, and is supposed to belong to the natural order Rubiaceæ. An active principle of a bitter taste has been obtained from it, soluble in water and alcohol and possessing an alkaline reaction and the same physiological action as the bark itself. This substance the authors regard as an alkaloid, and they have named it "doundakine." The alkaloid possesses poisonous properties, producing in the frog and guinea pig a cataleptic state with gradual failure first of the respiration and then of the heart's action. In dogs the catalepsy is not so evident. A poison obtained from the natives of Rio Nunez and used in chase and in war produced similar effects, and is believed by the authors to contain the same active principle as the doundaké bark.

A new substance, named by Meyer "thiophen" (*Berichte*, xvi., 1465), has been discovered in coal tar benzol. It has the formula C_4H_4S, and is, when pure, a colourless very mobile oil, boiling at 84° C., not miscible with water and having a sp. gr. of 1·062 at 23° C. In commercial coal tar benzol it exists to the extent of perhaps 0·5 per cent. only. The editor of *New Remedies* (p. 268) suggests that this new compound will probably be found in ichthyol, as that substance is known to contain a considerable proportion of combined sulphur. The discovery of thiophen arose from the observation that coal tar benzol when treated with isatin and sulphuric acid yields a magnificent blue colouring matter, which is not the case with benzol prepared from benzoic acid, from toluol or from urine. Benzol treated by sulphuric acid is rendered brown and no longer yields the blue colouring matter (indophenin), and this gave the clue to the process adopted for preparing the thiophen.

In a recent trade report Messrs. Gehe state that they have taken an opportunity while saturating a large quantity of benzoic acid sublimed from resin to isolate the adherent body, upon the presence of which depends the brown colour that is now one of the official characters of benzoic acid in the German Pharmacopœia. It is believed to be "benzophenid," and when treated with alkalies breaks up into benzoic acid and phenol. Some physiological experiments made with the substance by Dr. Robert, in Strassburg, seemed to show, however, that a similar decomposition does not take place in the body when "benzophenid" is administered inwardly; at least no increase of phenol has been detected in the urine; in this behaviour it resembles chloral hydrate, which does not yield chloroform. Rabbits did not appear to be affected by it when administered in doses of 10 grams, and an alcoholic solution injected under the skin of a frog produced no perceptible symptoms of poisoning.

Salicylate of bismuth has been reported to give good results in the treatment of various forms of diarrhœa as well as in typhoid fever. Commercial samples of the salt have, however, been found by M. Jaillet variable in characters and composition, and as a rule to yield to solvents uncombined salicylic acid (*Bull. Com.*, xi., 383), due probably to a defective mode of preparation. M. Jaillet states that there are two salts worth further investigation, an acid salicylate and a basic salicylate of bismuth. The acid salt is prepared by precipitating well crystallized nitrate of bismuth in five hundred times its weight of water, made faintly alkaline with caustic soda and containing salicylate of soda equal to double the weight of nitrate of bismuth employed. After settling, the supernatant liquid is decanted and the precipitate is washed three times with pure water to remove all traces of salicylate of soda and then dried rapidly at 40° C. Acid salicylate of bismuth occurs in white granular crystals that do not become coloured in the light and are only slightly soluble in water. If the washing of the precipitate be continued until the decantation water no longer gives a violet colour with perchloride of iron a yellowish dense amorphous basic compound is obtained, which is thought to be a mixture of two basic salicylates of bismuth. It would therefore appear that the compounds of bismuth with salicylic acid behave in the presence of water similarly to the compounds of that metal with nitric acid.

A nitrochlor-camphor has been prepared by M. Cazeneuve (*Journ. Pharm.*, [5], iv., 231) by heating normal monochlor-camphor with fuming nitric acid, precipitating with water and purifying the pasty mass by treatment successively with strong ammonia solution and 93° alcohol. By suitable treatment it can be obtained in magnificent prisms, melting at 95° C., insoluble in water, moderately soluble in cold alcohol and very soluble in hot alcohol, chloroform, carbon bisulphide and ether. Optically it has the peculiarity of being levogyre, whilst the monochlor-camphor from which it is derived is strongly dextrogyre. In constitution it probably corresponds to the nitrobrom-camphor derived from monobrom-camphor.

Herr Wieland (*Berichte*, xvi., 1989) claims pre-eminence in the list of indicators used in alkalimetry for the nitro-compound known as "ethyl-orange," which he says he has found to excel all other indicators in the delicacy and sharpness of its reaction. It is used in a 0·05 per cent. solution, two drops of which suffice for the coloration of 50 c.c. of liquid, and according to a comparative table given in the paper, the orange colour of 50 c.c. of such a liquid passes to a rose colour upon the addition of 0·3 to 0·5 c.c. of a centinormal acid solution, whilst methyl-orange solution under the same conditions requires the same quantity of acid to change the yellow colour to orange and from 0·8 to 1·0 c.c. to produce the rose colour. Ethyl orange is not affected by carbonic acid; but it should be mentioned that according to Herr Miller (*Berichte*, xvi., 1992) it has the disadvantage of being coloured rose by neutral sulphate of alumina, whilst with methyl-orange the change does not proceed beyond orange.

It is known that certain precipitates, such as sulphur in an emulsion, will pass through a paper filter. In order to overcome this difficulty M. de Boisbaudran (*Comptes Rendus*, xcvii., 625) treats the filter with a substance prepared by boiling filtering paper in aqua regia until the mass liquefies, then addding a large quantity of water and washing by decantation, or otherwise, the white precipitate that is formed. This substance is suspended in water and the mixture is poured into the filter and allowed to drain, when the water passes through and leaves upon the surface of the paper a coating which obstructs the pores.

According to Herr Knapp (*Archiv*, [3], xxi., 598) an establishment for the manufacture of santonin is being erected at Tschimkent, between Taschkent and the city of Turkestan. It is stated that all the material used by manufacturers of santonin grows in the neighbourhood, and a considerable advantage is expected to be realized in the saving of transport, the raw material weighing about fifty times as much as the finished product. The factory is intended to work up ten tons of seed every twenty-four hours.

In a memoir upon the causes of alteration in flour (*Comptes Rendus*, xcvii., 651) M. Balland states that the wheat grain contains a ferment which appears to reside in the neighbourhood of the albumen and the action of which is limited to the gluten. This ferment is insoluble and possesses the properties of the organized ferments; it resists a dry temperature of 100° C., but is destroyed by boiling water. Heat and moisture are indispensable to its development, a moist temperature of 25° C. being particularly favourable. When the grinding is skillfuly conducted most of this ferment remains in the bran, but if the stones be rotated too quickly the greater part of it passes into the flour, entailing the changes that occur in flour technically known as "heated."

In a contribution to the history of putrescence alkaloids Herr Poehl gives the results of some experiments upon the putrefaction of rye meal both free from and under the influence of ergot. (*Berichte*, xvi., 1975). The putrefaction appears to be preceded by the formation of peptone, such as can be set up in pure rye flour by the addition of peptic ferment. Herr Poehl states that from putrefying rye flour, both pure and ergotized, he has obtained, by shaking with ether and evaporating, residues which were sometimes liquid or semi-liquid and sometimes solid, with widely varying odours, sometimes resembling coniine, or with a disagreeable sweet aromatic smell, or recalling the smell of hawthorn, and which gave the usual alkaloidal reactions. It was found that the presence of ergot or the formation of mould in a paste of rye meal and water set up under certain conditions a peptic action upon the albuminoids of the meal and favoured their putrescent decomposition, the rate of decomposition being directly proportional to the peptonization. In the first stages of the change the putrescent decomposition takes place by far the most rapidly and extensively in rye meal to which peptic ferment has been added; next in order comes the meal containing ergot, followed by mouldy meal and then by pure meal. But with the lapse of time these differences are gradually diminished. The most essential conditions upon which the formation of putrescence alkaloids in ergotized rye meal depends appear to be (1) the conversion of starch into glucose; (2) fermentation of the glucose with formation of lactic acid; (3) peptonization of the albuminoids through the peptic action of the mycelium of *Claviceps purpurea* in the presence of lactic acid; (4) transformation of peptone to "ptomopeptone" and decomposition with the formation of putrescence alkaloids.

In a very lengthy communication (*Journ. prakt. Chemie*, xxviii., 82) the changes which take place in starch under the influence of inorganic and organic acids are exhaustively discussed by Herr Salomon. His experiments have led him to the conclusion that the saccharification of starch by dilute sulphuric acid does not consist in the splitting up of the starch molecule into sugar and dextrin, as stated by Musculus, but that the conversion takes place in stages, as affirmed by Payen, the successive products being starch, dextrin, and dextrose. The action of the sulphuric acid appears to resemble that which occurs in the formation of ethers. The acid unites with a definite quantity of starch, effects its hydration, and is then see free to unite with a fresh quantity of starch, the process going on continuously and the rapidity of the conversion being in proportion to the quantity of acid present. The saccharification of starch by organic acids proceeds in exactly the same manner; the action is much less energetic, but the successive products are identical.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE GOVERNMENT CINCHONA PLANTATIONS AT DARJEELING.

THE report of Surgeon-Major KING upon the Government Cinchona Plantations in Bengal, for 1882–83, which has been just received, contains some unusually interesting information respecting the progress of this early and most important experiment in cinchona acclimatization. In the first place the year has been marked by decisive steps taken to utilize the experience of the past in determining the kinds of cinchona which can be most advantageously cultivated at Darjeeling, the total number of plants showing a diminution of about fifty thousand, consequent upon the uprootal of upwards of sixty thousand inferior "hybrids" and "calisayas," which yielded bark that had proved upon analysis to be of poor quality. Following the same policy a hundred and sixty thousand "red bark" trees which had to be uprooted in the ordinary course were replaced by "yellow (Ledgeriana) bark" and superior "hybrids." Further, some new ground has been broken, which is also to be devoted to the best kind of "Ledgeriana" and "hybrids." As to the hybrids, it appears that among them several distinct forms are recognizable, and the results of analyses of bark from four of these were stated in a previous report, and showed a range of crystallized quinine sulphate from 0·97 to 2·87 per cent. The results of the analyses of the barks from four other hybrids are now reported, and these appear to indicate a very high quality, the poorest being nearly equal to the richest of the preceding year, whilst one yielded equal to 6·12 per cent. of quinine sulphate and 2·46 per cent. of cinchonidine, with traces of quinidine and 0·55 per cent. of cinchonine. The total number of plants standing in the plantations at the end of the year was 4,711,168, of which 3,713,200 were "succirubra," 662,998 "Ledgeriana," 304,378 unnamed "hybrids," and 30,592 of "other kinds." "Officinalis" plants are conspicuous by their absence, unless they are included among "other kinds;" but even then the species would seem to have almost disappeared from this part of India. Attempts to cultivate at Darjeeling the species of *Cinchona* and *Remijia* yielding "Carthagena" and "cuprea" barks have also up to the present time been practically a failure. Before leaving this part of the subject a word of commendation is due for the liberal policy of the Government, under which the remainder of the crop of seed from the "Ledgeriana" plants, after reserving what was required for the purposes of the plantation, was distributed gratuitously among private planters applying for a supply.

The crop of bark gathered in the year 1882–83 exceeded that harvested from these plantations in any preceding year, amounting to no less than 396,980 pounds of dry bark, of which 372,610 pounds consisted of "succirubra" bark, and the remainder principally of "calisaya" and "Ledgeriana." The estimated average cost per pound of producing this bark, calculated on the expenditure, is 2 annas 9·88 pies, equal, with the exchange at 1*s.* 8*d.* per rupee, to about 3½*d.* It will be observed that the greater portion of the bark crop consisted of "succirubra," which has hitherto been generally understood to contain as a rule only a small proportion of the most valuable alkaloid and much colouring matter. But the report contains an important statement with respect to "renewed" bark from "succirubra" trees that had had their original bark removed by Mr. MOENS' shaving process, which coupled with the recent report from Ceylon that the bark of the "succirubra" is there found to improve in quality as the plant approaches maturity, would seem to point to a more promising future for one of the most robust species of *Cinchona.* It appears, that although the bark renewed rather slowly, the new product showed a marked improvement in quality, a sample from the Mungpoo plantation yielding upon analysis equal to 3·70 per cent. of quinine sulphate, 4·88 per cent. of cinchonidine sulphate and 1·81 per cent. of cinchonine.

With the exception of a relatively small quantity, the whole of the bark harvested in the year was made over to the Government manufactory for conversion into "cinchona febrifuge." It is said to have included a larger proportion than usual of good bark, to which is mainly attributed the fact that the average quantity of febrifuge extracted from the bark used rose last year 2·73 per cent. The net product of the manufacture for the year is said to have been 10,363 pounds of ordinary, and 300 pounds of crystalline febrifuge, which, by adding the expense of manufacture to the cost price of the bark, as given above, is estimated to have been produced at an expenditure of rupees 8 : 8 (about 14*s.* 2*d.*) per pound. The demand for the febrifuge fell short of that in the previous year, and the stock in hand had increased nearly fifteen hundred pounds and reached nearly three thousand pounds; but this is not considered to be an excessive quantity, representing only about four months' consumption. The quantity of febrifuge supplied to Government during the year is reported as 4180½ pounds, and Dr. KING, somewhat ambitiously comparing it with an equal weight of quinine at 10*s.* per ounce, estimates the saving to the Government by its use at about £27,695. We do not think, however, that the "febrifuge" has yet reached the pitch of perfection at which it can claim to be equal to a similar weight of quinine, and if it be correct that apart from this point the result of the year's work is to show a profit equal to 6½ per cent. upon the capital, there is little necessity for any hypothetical inflation of the figures.

Much attention is reported to have been given during the year by Dr. King and Mr. Gammie to improvement in the process of manufacture of the febrifuge, and some advance is said to have been made. That improvement is desirable may perhaps be assumed from the fact that the falling off in the demand was mainly due to a diminished consumption at the Government Medical Depots of Calcutta and Madras. Dr. King is of opinion that better results might be obtained by a different and more costly process of manufacture, but possibly at an increased cost of the product. On the other hand, the report states that at the desire of the Secretary of State for India, a quantity of upwards of forty thousand pounds of bark ("succirubra" and "Ledger") has been sent to this country, where, it is understood, it will be converted into various kinds of "febrifuge," which will be returned to India for trial by the medical department.

The Inaugural Evening Meeting of the Pharmaceutical Society for the new session will take place on Wednesday next, and will be, as usual, devoted mainly to the reception of reports concerning the doings of old students in the School of Pharmacy and welcoming new ones. The attendance at these pleasant *réunions* is always good, and the fact that the Address to the Students is to be delivered by Professor Michael Foster, F.R.S., will, probably, induce even a larger number to make an effort to be present this year. The occasion will also be rendered additionally interesting by the presentation of the second "Hanbury Medal" to Mr. John Eliot Howard.

* * *

We have received a number of communications upon the subject of the Address delivered last week by Professor Attfield, at Southport, but we have not thought it necessary to publish them, as the opinions expressed are identical with those which have been reiterated again and again in the correspondence columns of this Journal. We have preferred rather to devote a considerable portion of the present number to the reproduction of comments upon the Address that have appeared in the public press, in order that our readers may have an opportunity of estimating the attitude, as thus indicated, that outside public opinion is likely to assume towards any attempt to secure legislation in the direction advocated by Professor Attfield. Several correspondents, also, have expressed a desire that the Address should be widely circulated and have inquired as to the possibility of purchasing copies for distribution. It will be seen from a letter which is printed on another page that Professor Attfield is taking the necessary steps to meet their wishes.

* * *

We regret to see that the editorial columns of the *British Medical Journal* were last week disfigured by one of the class of "leaderettes," so frequently met with now in the public press, in which prejudice and assumption are allowed to do duty for a knowledge of facts. The ignorance of the writer is shown by the statement that in the British Pharmacopœia "it is laid down that spirit of nitrous ether shall contain 2 per cent. by volume of pure nitrous ether." Even if unacquainted with the usually accepted explanation of the indication of the 2 per cent. separation which occurs during the application of the official test, an intelligent perusal of a report of the cases which furnished a text for his diatribe would have preserved him from making so incorrect an assertion. With respect to the tincture of quinine, too, which is alleged to have been found grossly deficient in its active and essential ingredients, it may be remarked that there were two charges in respect of this preparation before the magistrate. In one the correctness of the analysis of the public analyst was disputed, and the sample was referred to the chemists at Somerset House, who, as will be seen on turning to p. 259, have reported that it contained 8 grains of quinine sulphate to the ounce. In the other case, also, the defendant said that he was prepared to swear that in making the tincture he had used the proper quantity of quinine, but having omitted to accept a portion of the sample for independent analysis, and his statement being unsupported, he was convicted. The possibility, however, that the analyst made a mistake in this case as well as in the other is evidently not excluded.

* * *

A deputation from the Chemists and Druggists' Trade Association had an interview, on Tuesday, with the Vice-Chairman of the Board of Inland Revenue (Mr. Adam Young) and Major Keith-Falconer, the object of the visit being to urge on the Board the advisability of issuing an order making it compulsory on excise officers, when purchasing spirit for analysis, to leave with the seller a portion of the article purchased, to enable him, if he so wish, to obtain an independent analysis. It was pointed out that it frequently happens that a considerable time elapses between the date of a purchase and the institution of a prosecution in respect to it, and that meanwhile the spirit might have been in the hands of several persons. The Vice-Chairman at first suggested that the difficulty might be avoided by taking out a licence, which now costs only ten shillings a year; but after some further conversation he said he would recommend the Board to make the order asked for.

* * *

The recent meeting of the British Pharmaceutical Conference in Southport would appear to have been better attended than any previous meeting in any part of the country; the attendance book was signed by 193 persons, whereas the highest previous number of signatures was 170.

* * *

The meeting of the British Association in Southport, which was brought to a close on Wednesday, was also in respect to attendance a most successful one, the number having reached 2714. But it resembled the recent meeting of the American Association for the Advancement of Science in the dull mediocrity of the sectional proceedings, which to those who knew the Association in former days must have justified a regret that the jubilee meeting at York was not made to bring its history to a close.

A little fillip was given on the last day, when a rumour that the "missing link" of the Westminster Aquarium was to occupy the attention of the Department of Anthropology attracted a crowd to the meeting of Section D. The proceedings there, however, will hardly be considered, even by anthropologists, to have contributed much to the "advancement of science," and we think that most people will agree with the *Standard* that "when the British Association takes to expending its energies on the showman's monstrosities there is a distinct 'throw-back' to the time when the 'Transactions' of the Royal Society dealt with the monstrous births of calves with two heads." The next meeting of the Association is to commence in Montreal on Wednesday, the 27th of August, 1884.

* * *

At the sitting of the Academy of Sciences, on the 3rd instant, the President reminded the members that in another three days the Dean of the Academy and of the Institute, M. Chevreul, would enter his ninety-eighth year, not only retaining his physical vigour, but also his mental activity. He added that he looked forward with confidence to the time when the Academy and France would celebrate the centennary of one of the most illustrious scientific men of the age.

* * *

Indeed the office of Dean of the Institute would seem to be closely associated with longevity; for the present ages of the seven distinguished Frenchmen who share this dignity with M. Chevreul are—M. Barthélemy Saint-Hilaire, the youngest, seventy-eight years: M. Charles Lucas, eighty years; M. Boussingault, eighty-one years; M. Dumont, eighty-two years; M. Dumas, eighty-three years; M. Milne-Edwards, eighty-three years; and M. Mignet, eighty-seven years.

* * *

As the Patron of the First International Pharmaceutical Exhibition, His Imperial Highness the Archduke Carl Ludwig invited Herr A. von Waldheim, the President, Dr. Hellmann, the Vice-President, Herr Seipl, the Treasurer, and Dr. Heger, the Secretary to the Executive Committee of that undertaking, to a *dejeuner* on Sunday, the 16th inst. In acknowledging the toast of his health, proposed by Herr von Waldheim, His Imperial Highness said that pharmacists might reckon upon him in the future to do anything that lay in his power to support them in their useful work. It is intended that if possible the formal distribution of prizes shall take place before the end of the present month.

* * *

In Toronto a man named Robertson has been sentenced to pay a fine of five hundred dollars or undergo sixty days' imprisonment for having forged the trade mark of J. C. Ayer and Co. to labels placed on pill boxes. The prisoner appears to have offered a lot of "Ayer's Pills" at two-thirds the market price to a firm which took the precaution before buying to communicate with Messrs. Ayer, so that the fraud was thus discovered. The prisoner said he had sold only one gross of the pills, but admitted that he had prepared about two hundred dollars' worth which he expected would have sold for between one and two thousand dollars. As it was, however, the pills were seized and destroyed, together with boxes, labels and electrotypes that had cost him at least another thousand dollars.

Proceedings of Scientific Societies.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The meeting of the above Association commenced on Wednesday, September 19, at Southport, under the Presidency of Arthur Cayley, M.A., D.C.L., LL.D., F.R.S., Sadlerian Professor of Pure Mathematics in the University of Cambridge.

The President's Address.*

Since our last meeting we have been deprived of three of our most distinguished members. The loss by the death of Professor Henry John Stephen Smith is a very grievous one to those who knew and admired and loved him, to his University, and to mathematical science, which he cultivated with such ardour and success. I need hardly recall that the branch of mathematics to which he had specially devoted himself was that most interesting and difficult one, the Theory of Numbers. The immense range of this subject, connected with and ramifying into so many others, is nowhere so well seen as in the series of reports on the progress thereof, brought up unfortunately only to the year 1865, contributed by him to the Reports of the Association; but it will still better appear when to these are united (as will be done in the collected works in course of publication by the Clarendon Press) his other mathematical writings, many of them containing his own further developments of theories referred to in the reports. There have been recently or are being published many such collected editions — Abel, Cauchy, Clifford, Gauss, Green, Jacobi, Lagrange, Maxwell, Riemann, Steiner. Among these the works of Henry Smith will occupy a worthy position.

More recently, General Sir Edward Sabine, K.C.B., for twenty-one years general secretary of the Association, and a trustee, President of the meeting at Belfast in the year 1852, and for many years treasurer and afterwards President of the Royal Society, has been taken from us, at an age exceeding the ordinary age of man. Born October 1788, he entered the Royal Artillery in 1803, and commanded batteries at the siege of Fort Erie in 1814; made magnetic and other observations in Ross and Parry's North Polar exploration in 1818–19, and in a series of other voyages. He contributed to the Association reports on Magnetic Forces in 1836–7–8, and about forty papers to the 'Philosophical Transactions'; originated the system of Magnetic Observatories, and otherwise signally promoted the science of Terrestrial Magnetism.

There is yet a very great loss: another late President and trustee of the Association, one who has done for it so much, and has so often attended the meetings, whose presence among us at this meeting we might have hoped for—the President of the Royal Society, William Spottiswoode. It is unnecessary to say anything of his various merits: the place of his burial, the crowd of sorrowing friends who were present in the Abbey, bear witness to the esteem in which he was held.

I take the opportunity of mentioning the completion of a work promoted by the Association: the determination by Mr. James Glaisher of the least factors of the missing three out of the first nine million numbers: the volume containing the sixth million is now published.

I wish to speak to you to-night upon Mathematics. I am quite aware of the difficulty arising from the abstract nature of my subject; and if, as I fear, many or some of you, recalling the presidential addresses at former meetings—for instance, the *résumé* and survey which we had at York of the progress, during the half century of the lifetime of the Association, of a whole circle of sciences—biology, palæontology, geology, astronomy, chemistry—so much more familiar to you, and in which there was so

* The report represents the address as delivered, its great length as originally written preventing the insertion of the omitted passages.

much to tell of the fairy-tales of science; or at Southampton, the discourse of my friend who has in such kind terms introduced me to you, on the wondrous practical applications of science to electric lighting, telegraphy, the St. Gothard Tunnel and the Suez Canal, gun-cotton, and a host of other purposes, and with the grand concluding speculation on the conservation of solar energy: if, I say, recalling these or any earlier addresses, you should wish that you were now about to have, from a different president, a discourse on a different subject, I can very well sympathize with you in the feeling.

But be this as it may, I think it is more respectful to you that I should speak to you upon and do my best to interest you in the subject which has occupied me, and in which I am myself most interested. And in another point of view, I think it is right that the address of a president should be on his own subject, and that different subjects should be thus brought in turn before the meetings. So much the worse, it may be, for a particular meeting; but the meeting is the individual, which on evolution principles must be sacrificed for the development of the race.

Mathematics connect themselves on the one side with common life and the physical sciences; on the other side with philosophy, in regard to our notions of space and time, and in the questions which have arisen as to the universality and necessity of the truths of mathematics, and the foundation of our knowledge of them. I would remark here that the connection (if it exists) of arithmetic and algebra with the notion of time is far less obvious than that of geometry with the notion of space.

As to the former side, I am not making before you a defence of mathematics, but if I were I should desire to do it—in such manner as in the 'Republic' Socrates was required to defend justice, quite irrespectively of the worldy advantages which may accompany a life of virtue and justice, and to show that, independently of all these, justice was a thing desirable in itself and for its own sake—*not* by speaking to you of the utility of mathematics in any of the questions of common life or of physical science. Still less would I speak of this utility before, I trust, a friendly audience, interested or willing to appreciate an interest in mathematics in itself and for its own sake. I would, on the contrary, rather consider the obligations of mathematics to these different subjects as the sources of mathematical theories now as remote from them, and in as different a region of thought—for instance, geometry from the measurement of land, or the Theory of Numbers from arithmetic—as a river at its mouth is from its mountain source.

On the other side, the general opinion has been and is that it is indeed by experience that we arrive at the truths of mathematics, but that experience is not their proper foundation: the mind itself contributes something. This is involved in the Platonic theory of reminiscence: looking at two things, trees or stones or anything else, which seem to us more or less equal, we arrive at the idea of equality: but we must have had this idea of equality before the time when first seeing the two things we were led to regard them as coming up more or less perfectly to this idea of equality; and the like as regards our idea of the beautiful, and in other cases.

The same view is expressed in the answer of Leibnitz, the *nisi intellectus ipse*, to the scholastic dictum, *nihil in intellectu quod non prius in sensu*: there is nothing in the intellect which was not first in sensation, except (said Leibnitz) the intellect itself. And so again in the 'Critick of Pure Reason,' Kant's view is that while there is no doubt but that all our cognition begins with experience, we are nevertheless in possession of cognitions *à priori*, independent, not of this or that experience, but absolutely so of all experience, and in particular that the axioms of mathematics furnish an example of such cognitions *à priori*. Kant holds further that space is no empirical conception which has been derived from external experiences, but that in order that sensations may be referred to something external, the representation of space must already lie at the foundation; and that the external experience is itself first only possible by this represention of space. And in like manner time is no empirical conception which can be deduced from an experience, but it is a necessary representation lying at the foundation of all intuitions.

And so in regard to mathematics, Sir W. R. Hamilton, in an Introductory Lecture on Astronomy (1836), observes: "These purely mathematical sciences of algebra and geometry are sciences of the pure reason, deriving no weight and no assistance from experiment, and isolated or at least isolable from all outward and accidental phenomena. The idea of order with its subordinate ideas of number and figure, we must not indeed call innate ideas, if that phrase be defined to imply that all men must possess them with equal clearness and fulness: they are, however, ideas which seem to be so far born with us that the possession of them in any conceivable degree is only the development of our original powers, the unfolding of our proper humanity."

The general question of the ideas of space and time, the axioms and definitions of geometry, the axioms relating to number, and the nature of mathematical reasoning, are fully and ably discussed in Whewell's 'Philosophy of the Inductive Sciences' (1840), which may be regarded as containing an exposition of the whole theory.

But it is maintained by John Stuart Mill that the truths of mathematics, in particular those of geometry, rest on experience; and as regards geometry, the same view is on very different grounds maintained by the mathematician Riemann.

It is not so easy as at first sight it appears to make out how far the views taken by Mill in his 'System of Logic Ratiocinative and Inductive' (9th ed., 1879) are absolutely contradictory to those which have been spoken of; they profess to be so; there are most definite assertions (supported by argument), for instance, p. 263:—"It remains to inquire what is the ground of our belief in axioms, what is the evidence on which they rest. I answer, they are experimental truths, generalizations from experience. The proposition 'Two straight lines cannot enclose a space,' or, in other words, two straight lines which have once met cannot meet again, is an induction from the evidence of our senses." But I cannot help considering a previous argument (p. 259) as very materially modifying this absolute contradiction. After inquiring "Why are mathematics by almost all philosophers . . . considered to be independent of the evidence of experience and observation, and characterized as systems of necessary truth?" Mill proceeds (I quote the whole passage) as follows:—"The answer I conceive to be that this character of necessity ascribed to the truths of mathematics, and even (with some reservations to be hereafter made) the peculiar certainty ascribed to them, is a delusion, in order to sustain which it is necessary to suppose that those truths relate to and express the properties of purely imaginary objects. It is acknowledged that the conclusions of geometry are derived partly at least from the so-called definitions, and that these definitions are assumed to be correct representations, as far as they go, of the objects with which geometry is conversant. Now, we have pointed out that from a definition as such no proposition unless it be one concerning the meaning of a word can ever follow, and that what apparently follows from a definition, follows in reality from an implied assumption that there exists a real thing conformable thereto. This assumption in the case of the definitions of geometry is not strictly true: there exist no real things exactly conformable to the definitions. There exist no real points without magnitude, no lines without breadth, nor perfectly straight, no circles with all their radii exactly equal, nor squares with all their angles perfectly right. It will be said that the assumption does not extend to the actual but only to the possible existence of such things.

I answer that according to every test we have of possibility they are not even possible. Their existence, so far as we can form any judgment, would seem to be inconsistent with the physical constitution of our planet at least, if not of the universal [*sic.*]. To get rid of this difficulty and at the same time to save the credit of the supposed system of necessary truth, it is customary to say that the points, lines, circles and squares which are the subjects of geometry exist in our conceptions merely and are parts of our minds; which minds by working on their own materials construct an *à priori* science, the evidence of which is purely mental and has nothing to do with outward experience. By howsoever high authority this doctrine has been sanctioned, it appears to me psychologically incorrect. The points, lines and squares which anyone has in his mind are (as I apprehend) simply copies of the points, lines and squares which he has known in his experience. Our idea of a point I apprehend to be simply our idea of the *minimum visibile*, the small portion of surface which we can see. We can reason about a line as if it had no breadth, because we have a power which we can exercise over the operations of our minds: the power, when a perception is present to our senses or a conception to our intellects, of *attending* to a part only of that perception or conception instead of the whole. But we cannot *conceive* a line without breadth: we can form no mental picture of such a line; all the lines which we have in our mind are lines possessing breadth. If any one doubt this, we may refer him to his own experience. I much question if anyone who fancies that he can conceive of a mathematical line thinks so from the evidence of his own consciousness. I suspect that it is rather because he supposes that unless such a perception be possible, mathematics could not exist as a science: a supposition which there will be no difficulty in showing to be groundless."

I think it may be at once conceded that the truths of geometry are truths precisely because they relate to and express the properties of what Mill calls "purely imaginary objects;" that these objects do not exist in Mill's sense, that they do not exist in nature, may also be granted; that they are "not even possible," if this means not possible in an existing nature, may also be granted. That we cannot "conceive" them depends on the meaning which we attach to the word conceive. I would myself say that the purely imaginary objects are the only realities, the ὄντως ὄντα, in regard to which the corresponding physical objects are as the shadows in the cave; and it is only by means of them that we are able to deny the existence of a corresponding physical object; if there is no conception of straightness, then it is meaningless to deny the existence of a perfectly straight line.

But at any rate the objects of geometrical truth are the so-called imaginary objects of Mill, and the truths of geometry are only true, and *à fortiori* are only necessarily true, in regard to these so-called imaginary objects; and, these objects, points, lines, circles, etc., in the mathematical sense of the terms, have a likeness to and are represented more or less imperfectly, and from a geometer's point of view no matter how imperfectly, by corresponding physical points, lines, circles, etc. I shall have to return to geometry, and will then speak of Riemann, but I will first refer to another passage of the 'Logic.'

Speaking of the truths of arithmetic Mill says (p. 297) that even here there is one hypothetical element: "In all propositions concerning numbers a condition is implied without which none of them would be true, and that condition is an assumption which may be false. The condition is that $1 = 1$: that all the numbers are numbers of the same or of equal units." Here at least the assumption may be absolutely true; one shilling = one shilling in purchasing power, although they may not be absolutely of the same weight and fineness: but it is hardly necessary; one coin + one coin = two coins, even if the one be a shilling and the other a half-crown. In fact, whatever difficulty be raisable as to geometry, it seems to me that no similar difficulty applies to arithmetic; mathematician or not, we have each of us, in its most abstract form, the idea of a number; we can each of us appreciate the truth of a proposition in regard to numbers; and we cannot but see that a truth in regard to numbers is something different in kind from an experimental truth generalized from experience. Compare, for instance, the proposition that the sun, having already risen so many times, will rise to-morrow, and the next day, and the day after that, and so on; and the proposition that even and odd numbers succeed each other alternately *ad infinitum*: the latter at least seems to have the characters of universality and necessity. Or again, suppose a proposition observed to hold good for a long series of numbers, one thousand numbers, two thousand numbers, as the case may be: this is not only no proof, but it is absolutely no evidence, that the proposition is a true proposition, holding good for all numbers whatever; there are in the Theory of Numbers very remarkable instances of propositions observed to hold good for very long series of numbers and which are nevertheless untrue.

I pass in review certain mathematical theories.

In arithmetic and algebra, or say in analysis, the numbers or magnitudes which we represent by symbols are in the first instance ordinary (that is, positive) numbers or magnitudes. We have also in analysis and in analytical geometry *negative* magnitudes; there has been in regard to these plenty of philosophical discussion, and I might refer to Kant's paper, 'Ueber die negativen Grössen in die Weltweisheit' (1763); but the notion of a negative magnitude has become quite a familiar one, and has extended itself into common phraseology. I may remark that it is used in a very refined manner in bookkeeping by double entry.

But it is far otherwise with the notion which is really the fundamental one (and I cannot too strongly emphasise the assertion) underlying and pervading the whole of modern analysis and geometry, that of imaginary magnitude in analysis and of imaginary space (or space as a *locus in quo* of imaginary points and figures) in geometry: I use in each case the word imaginary as including real. This has not been, so far as I am aware, a subject of philosophical discussion or inquiry. As regards the older metaphysical writers this would be quite accounted for by saying that they knew nothing, and were not bound to know anything, about it; but at present, and, considering the prominent position which the notion occupies—say even that the conclusion were that the notion belongs to mere technical mathematics, or has reference to nonentities in regard to which no science is possible, still it seems to me that (as a subject of philosophical discussion) the notion ought not to be thus ignored; it should at least be shown that there is a right to ignore it.

Although in logical order I should perhaps now speak of the notion just referred to, it will be convenient to speak first of some other quasi-geometrical notions; those of more-than-three-dimensional space, and of non-Euclidian two- and three-dimensional space, and also of the generalized notion of distance. It is in connection with these that Riemann considered that our notion of space is founded on experience, or rather that it is only by experience that we know that our space is Euclidian space.

It is well known that Euclid's twelfth axiom, even in Playfair's form of it, has been considered as needing demonstration; and that Lobatschewsky constructed a perfectly consistent theory, wherein this axiom was assumed not to hold good, or say a system of non-Euclidian plane geometry. There is a like system of non-Euclidian solid geometry. My own view is that Euclid's twelfth axiom in Playfair's form of it does not need demonstration, but is part of our notion of space, of the physical space of our experience—the space, that is, which we become acquainted with by experience, but which is the representation lying at the foundation of all external experience. Riemann's view before referred to may I think be said to be that, having *in intellectu* a more general notion of space (in fact a notion of non-Euclidian space), we learn by experience that space (the physical space of our experience) is, if not exactly, at least to the highest degree of approximation, Euclidian space.

But suppose the physical space of our experience to be thus only approximately Euclidian space, what is the consequence which follows? *Not* that the propositions of geometry are only approximately true, but that they remain absolutely true in regard to that Euclidian space which has been so long regarded as being the physical space of our experience.

It is interesting to consider two different ways in which, without any modification at all of our notion of space, we can arrive at a system of non-Euclidian (plane or two-dimensional) geometry; and the doing so will, I think, throw some light on the whole question.

First, imagine the earth a perfectly smooth sphere; understand by a plane the surface of the earth, and by a line the apparently straight line (in fact an arc of great circle) drawn on the surface; what experience would in the first instance teach would be Euclidian geometry; there would be intersecting lines which produced a few miles or so would seem to go on diverging: and apparently parallel lines which would exhibit no tendency to approach each other; and the inhabitants might very well conceive that they had by experience established the axiom that two straight lines cannot enclose a space, and the axiom as to parallel lines. A more extended experience and more accurate measurements would teach them that the axioms were each of them false; and that any two lines if produced far enough each way, would meet in two points: they would in fact arrive at a spherical geometry, accurately representing the properties of the two-dimensional space of their experience. But their original Euclidian geometry would not the less be a true system: only it would apply to an ideal space, not the space of their experience.

Secondly, consider an ordinary, indefinitely extended plane; and let us modify only the notion of distance. We measure distance, say, by a yard measure or a foot rule, anything which is short enough to make the fractions of it of no consequence (in mathematical language by an infinitesimal element of length); imagine, then, the length of this rule constantly changing (as it might do by an alteration of temperature), but under the condition that its actual length shall depend only on its situation on the plane and on its direction: viz., if for a given situation and direction it has a certain length, then whenever it comes back to the same situation and direction it must have the same length. The distance along a given straight or curved line between any two points could then be measured in the ordinary manner with this rule, and would have a perfectly determinate value: it could be measured over and over again, and would always be the same; but of course it would be the distance, not in the ordinary acceptation of the term, but in quite a different acceptation. Or in a somewhat different way: if the rate of progress from a given point in a given direction be conceived as depending only on the configuration of the ground, and the distance along a given path between any two points thereof be measured by the time required for traversing it, then in this way also the distance would have a perfectly determinate value; but it would be a distance, not in the ordinary acceptation of the term, but in quite a different acceptation. And corresponding to the new notion of distance we should have a new, non-Euclidian system of plane geometry; all theorems involving the notion of distance would be altered.

We may proceed further. Suppose that as the rule moves away from a fixed central point of the plane it becomes shorter and shorter; if this shortening takes place with sufficient rapidity, it may very well be that a distance which in the ordinary sense of the word is finite will in the new sense be infinite; no number of repetitions of the length of the ever-shortening rule will be sufficient to cover it. There will be surrounding the central point a certain finite area such that (in the new acceptation of the term distance) each point of the boundary thereof will be at an infinite distance from the central point; the points outside this area you cannot by any means arrive at with your rule; they will form a *terra incognita* or rather an unknowable land: in mathematical language, an imaginary or impossible space: and the plane space of the theory will be that within the finite area—that is, it will be finite instead of infinite.

We thus with a proper law of shortening arrive at a system of non-Euclidian geometry which is essentially that of Lobatschewsky. But in so obtaining it we put out of sight its relation to spherical geometry: the three geometries (spherical, Euclidian and Lobatschewsky's) should be regarded as members of a system: viz., they are the geometries of a plane (two-dimensional) space of constant positive curvature, zero curvature, and constant negative curvature respectively; or again, they are the plane geometries corresponding to three different notions of distance; in this point of view they are Klein's elliptic, parabolic, and hyperbolic geometries respectively.

Next as regards solid geometry: we can by a modification of the notion of distance (such as has just been explained in regard to Lobatschewsky's system) pass from our present system to a non-Euclidian system; for the other mode of passing to a non-Euclidian system it would be necessary to regard our space as a flat three-dimensional space existing in a space of four dimensions (*i.e.*, as the analogue of a plane existing in ordinary space); and to substitute for such flat three-dimensional space a curved three-dimensional space, say of constant positive or negative curvature. In regarding the physical space of our experience as possibly non-Euclidian, Riemann's idea seems to be that of modifying the notion of distance, not that of treating it as a locus in four-dimensional space.

I have just come to speak of four-dimensional space. What meaning do we attach to it? Or can we attach to it any meaning? It may be at once admitted that we cannot conceive of a fourth dimension of space; that space as we conceive of it, and the physical space of our experience, are alike three-dimensional; but we can, I think, conceive of space as being two- or even one-dimensional; we can imagine rational beings living in a one-dimensional space (a line) or in a two-dimensional space (a surface) and conceiving of space accordingly, and to whom, therefore, a two-dimensional space, or (as the case may be) a three-dimensional space would be as inconceivable as a four-dimensional space is to us. And very curious speculative questions arise. Suppose the one-dimensional space a right line, and that it afterwards becomes a curved line, would there be any indication of the change? Or, if originally a curved line, would there be anything to suggest to them that it was not a right line? Probably not, for a one-dimensional geometry hardly exists. But let the space be two-dimensional, and imagine it originally a plane, and afterwards bent (converted, that is, into some form of developable surface) or converted into a curved surface, or imagine it originally a developable or curved surface. In the former case there should be an indication of the change, for the geometry originally applicable to the space of their experience (our own Euclidian geometry) would cease to be applicable; but the change could not be apprehended by them as a bending or deformation of the plane, for this would imply the notion of a three-dimensional space in which this bending or deformation could take place. In the latter case their geometry would be that appropriate to the developable or curved surface which is their space, viz., this would be their Euclidian geometry, would they ever have arrived at our own more simple system? But take the case where the two-dimensional space is a plane, and imagine the beings of such a space familiar with our own Euclidian plane geometry; if, a third dimension being still inconceivable by them, they were by their geometry or otherwise led to the notion of it, there would be nothing to prevent them from forming a science such as our own science of three-dimensional geometry.

Evidently all the foregoing questions present themselves in regard to ourselves, and to three-dimensional space as we conceive of it, and as the physical space of our experience. And I need hardly say that the first step is the difficulty, and that granting a fourth dimension we may assume as many more dimensions as we please. But whatever answer be given to them, we have, as a branch of mathematics, potentially, if not actually, an analytical geometry of n-dimensional space. I shall have to speak again upon this.

Coming now to the fundamental notion already referred to, that of imaginary magnitude in analysis and imaginary space in geometry, I connect this with two great discoveries in mathematics made in the first half of the seventeeth century, Harriot's representation of an equation in the form $f(x)=0$, and the consequent notion of the roots of an equation as derived from the linear factors of $f(x)$, and Descartes' method of co-ordinates. By these we are led analytically to the notion of imaginary points in geometry; for instance, we arrive at the theorem that a straight line and a circle intersect *always* in two points real or imaginary. The conclusion as to the two points of intersection cannot be contradicted by experience: take a sheet of paper and draw on it the straight line and circle, and try. But you might say, or at least be strongly tempted to say, that it is meaningless. The question of course arises, What is the meaning of an imaginary point? and further, In what manner can the notion be arrived at geometrically?

There is a well-known construction in perspective for drawing lines through the intersection of two lines, which are so nearly parallel as not to meet within the limits of a sheet of paper. You have two given lines which do not meet, and you draw a third line, which, when the lines are all of them produced, is found to pass through the intersection of the given lines. If instead of lines we have two circular arcs not meeting each other, then we can, by means of these arcs construct a line; and if on completing the circles it is found that the circles intersect each other in two real points, then it will be found that the line passes through these two points: if the circles appear not to intersect, then the line will appear not to intersect either of the circles. But the geometrical construction being in each case the same, we say that in the second case also the line passes through the two intersections of the circles.

Of course it may be said in reply that the conclusion is a very natural one, provided we assume the existence of imaginary points; and that, this assumption not being made, then, if the circles do not intersect, it is meaningless to assert that the line passes through their points of intersection. The difficulty is not got over by the analytical method before referred to, for this introduces difficulties of its own: is there in a plane a point the coordinates of which have given imaginary values? As a matter of fact, we do consider in plane geometry imaginary points introduced into the theory analytically or geometrically as above.

The like considerations apply to solid geometry, and we thus arrive at the notion of imaginary space as a *locus in quo* of imaginary points and figures.

I have used the word imaginary rather than complex, and I repeat that the word has been used as including real. But, this once understood, the word becomes in many cases superfluous, and the use of it would even be misleading. Thus, "a problem has so many solutions:" this means, so many imaginary (including real) solutions. But if it were said that the problem had "so many imaginary solutions," the word "imaginary" would here be understood to be used in opposition to real. I give this explanation the better to point out how wide the application of the notion of the imaginary is—viz. (unless expressly or by implication excluded), it is a notion implied and presupposed in all the conclusions of modern analysis and geometry. It is, as I have said, the fundamental notion underlying and pervading the whole of these branches of mathematical science.

I consider the question of the geometrical representation of an imaginary variable. We represent the imaginary variable $x+iy$ by means of a point in a plane, the coordinates of which are (x, y). This idea, due to Gauss, dates from about the year 1831. We thus picture to ourselves the succession of values of the imaginary variable $x+iy$ by means of the motion of the representative point: for instance, the succession of values corresponding to the motion of the point along a closed curve to its original position. The value $X+iY$ of the function can of course be represented by means of a point (taken for greater convenience in a different plane), the coordinates of which are X,Y.

We may consider in general two points, moving each in its own plane, so that the position of one of them determines the position of the other, and consequently the motion of the one determines the motion of the other: for instance, the two points may be the tracing-point and the pencil of a pentagraph. You may with the first point draw any figure you please, there will be a corresponding figure drawn by the second point: for a good pentagraph, a copy on a different scale (it may be); for a badly-adjusted pentagraph, a distorted copy: but the one figure will always be a sort of copy of the first, so that to each point of the one figure there will correspond a point of the other figure.

In the case above referred to, where one point represents the value $x+iy$ of the imaginary variable and the other the value $X+iY$ of some function $\phi(x+iy)$ of that variable, there is a remarkable relation between the two figures: this is the relation of orthomorphic projection, the same which presents itself between a portion of the earth's surface, and the representation thereof by a map on the stereographic projection or on Mercator's projection—viz. any indefinitely small area of the one figure is represented in the other figure by an indefinitely small area of the same shape. There will possibly be for different parts of the figure great variations of scale, but the shape will be unaltered; if for the one area the boundary is a circle, then for the other area the boundary will be a circle; if for one it is an equilateral triangle, then for the other it will be an equilateral triangle.

I have been speaking of an imaginary variable $(x+iy)$, and of a function $\phi(x+iy)=X+iY$ of that variable, but the theory may equally well be stated in regard to a plane curve: in fact, the $x+iy$ and the $X+iY$ are two imaginary variables connected by an equation; say their values are u and v, connected by an equation $F(u, v)=0$; then, regarding u, v as the coordinates of a point *in plano*, this will be a point on the curve represented by the equation. The curve, in the widest sense of the expression, is the whole series of points, real or imaginary, the coordinates of which satisfy the equation, and these are exhibited by the foregoing corresponding figures in two planes; but in the ordinary sense the curve is the series of real points, with coordinates u, v, which satisfy the equation.

In geometry it is the curve, whether defined by means of its equation, or in any other manner, which is the subject for contemplation and study. But we also use the curve as a representation of its equation—that is, of the relation existing between two magnitudes x, y, which are taken out as the coordinates of a point on the curve. Such employment of a curve for all sorts of purposes—the fluctuations of the barometer, the Cambridge boat races, or the Funds—is familiar to most of you. It is in like manner convenient in analysis, for exhibiting the relations between any three magnitudes x, y, z, to regard them as the coordinates of a point in space; and, on the like ground, we should at least wish to regard any four or more magnitudes as the coordinates of a point in space of a corresponding number of dimensions. Starting with the hypothesis of such a space, and of points therein each determined by means of its coordinates, it is found possible to establish a system of n-dimensional geometry analogous in every respect to our two-and three-dimensional geometries, and to a very considerable extent serving to exhibit the relations of the variables. To quote from my memoir 'On Abstract Geometry" (1869): "The science presents itself in two ways: as a legitimate extension of the ordinary two- and three-dimensional geometries, and as a need in these geometries and in analysis generally. In fact, whenever we are concerned with quantities connected in any manner, and which are considered as variable or determinable, then the nature of the connection between the quantities is frequently rendered more intelligible by regarding them (if two or three in number) as the coordinates of a point in a plane or in space. For more than three quantities there is, from the greater complexity of the case, the greater need of such a representation; but this can only be obtained by means of the notion of a space of the proper dimensionality; and to use such representation we require a corresponding geometry. An important instance in plane geometry has already presented itself in the question of the number of curves which satisfy given conditions; the conditions imply relations between the coefficients in the equation of the curve; and for the better understanding of these relations it was expedient to consider the coefficients as the coordinates of a point in a space of the proper dimensionality."

It is to be borne in mind that the space, whatever its dimensionality may be, must always be regarded as an imaginary or complex space such as the two- or three-dimensional space of ordinary geometry; the advantages of the representation would otherwise altogether fail to be obtained.

I omit some further developments in regard to geometry, and all that I have written as to the connection of mathematics with the notion of time.

I said that I would speak to you, not of the utility of mathematics in any of the questions of common life or of physical science, but rather of the obligations of mathematics to these different subjects. The consideration which thus presents itself is in a great measure that of the history of the development of the different branches of mathematical science in connection with the older physical sciences, astronomy and mechanics: the mathematical theory is in the first instance suggested by some question of common life or of physical science, is pursued and studied quite independently thereof, and perhaps after a long interval comes in contact with it, or with quite a different question. Geometry and algebra must, I think, be considered as each of them originating in connection with objects or questions of common life —geometry, notwithstanding its name, hardly in the measurement of land, but rather from the contemplation of such forms as the straight line, the circle, the ball, the top (or sugar-loaf): the Greek geometers appropriated for the geometrical forms corresponding to the last two of these, the words *σφαῖρα* and *κῶνος*, our cone and sphere, and they extended the word cone to mean the complete figure obtained by producing the straight lines of the surface both ways indefinitely. And so algebra would seem to have arisen from the sort of easy puzzles in regard to numbers which may be made, either in the picturesque forms of the Bija-Ganita with its maiden with the beautiful locks, and its swarms of bees amid the fragrant blossoms, and the one queen-bee left humming around the lotus flower; or in the more prosaic form in which a student has presented to him in a modern text-book a problem leading to a simple equation.

The Greek geometry may be regarded as beginning with Plato (B.C. 430–347): the notions of geometrical analysis, loci, and the conic sections are attributed to him, and there are in his Dialogues many very interesting allusions to mathematical questions: in particular the passage in the 'Theætetus,' where he affirms the incommensurability of the sides of certain squares. But the earliest extant writings are those of Euclid (B.C. 285): there is hardly anything in mathematics more beautiful than his wondrous fifth book; and he has also in the seventh, eighth, ninth and tenth books fully and ably developed the first principles of the Theory of Numbers, including the theory of incommensurables. We have next Apollonius (about B.C. 247), and Archimedes (B.C. 287–212), both geometers of the highest merit, and the latter of them the founder of the science of statics (including therein hydrostatics): his dictum about the lever, his 'Εὕρηκα,' and the story of the defence of Syracuse, are well known. Following these we have a worthy series of names, including the astronomers Hipparchus (B.C. 150) and Ptolemy (A.D. 125), and ending, say, with Pappus (A.D. 400), but continued by their Arabian commentators, and the Italian and other European geometers of the sixteenth century and later, who pursued the Greek geometry.

The Greek arithmetic was, from the want of a proper notation, singularly cumbrous and difficult; and it was for astronomical purposes superseded by the sexagesimal arithmetic, attributed to Ptolemy, but probably known before his time. The use of the present so-called Arabic figures became general among Arabian writers on arithmetic and astronomy about the middle of the tenth century, but was not introduced into Europe until about two centuries later. Algebra among the Greeks is represented almost exclusively by the treatise of Diophantus (A.D. 150), in fact a work on the Theory of Numbers containing questions relating to square and cube numbers, and other properties of numbers, with their solutions; this has no historical connection with the later algebra, introduced into Italy from the East by Leonardi Bonacci, of Pisa (A.D. 1202–1208), and successfully cultivated in the fifteenth and sixteenth centuries by Lucas Paciolus, or de Burgo, Tartaglia, Cardan and Ferrari. Later on, we have Vieta (1540–1603), Harriot, already referred to, Wallis and others.

Astronomy is of course intimately connected with geometry; the most simple facts of observation of the heavenly bodies can only be *stated* in geometrical language: for instance, that the stars describe circles about the pole-star, or that the different positions of the sun among the fixed stars in the course of the year form a circle. For astronomical calculations it was found necessary to determine the arc of a circle by means of its chord: the notion is as old as Hipparchus, a work of whom is referred to as consisting of twelve books on the chords of circular arcs; we have (A.D. 125) Ptolemy's 'Almagest,' the first book of which contains a table of arcs and chords with the method of construction; and among other theorems on the subject he gives there the theorem afterwards inserted in Euclid (Book VI., Prop. D) relating to the rectangle contained by the diagonals of a quadrilateral inscribed in a circle. The Arabians made the improvement of using in place of the chord of an arc the sine, or half chord of double the arc; and so brought the theory into the form in which it is used in modern trigonometry: the before-mentioned theorem of Ptolemy, or rather a particular case of it, translated into the notation of sines, gives the expression for the sine of the sum of two arcs in terms of the sines and cosines of the component arcs; and it is thus the fundamental theorem on the subject. We have in the fifteenth and sixteenth centuries a series of mathematicians who with wonderful enthusiasm and perseverance calculated tables of the trigonometrical or circular functions, Purbach, Müller or Regiomontanus, Copernicus, Reinhold, Maurolycus, Vieta, and many others; the tabulations of the functions tangent and secant arc due to Reinhold and Maurolycus respectively.

Logarithms were invented, not exclusively with reference to the calculation of trigonometrical tables, but in order to facilitate numerical calculations generally; the invention is due to John Napier of Merchiston, who died in 1618 at sixty-seven years of age; the notion was based upon refined mathematical reasoning on the comparison of the spaces described by two points, the one moving with a uniform velocity, the other with a velocity varying according to a given law. It is to be observed that Napier's logarithms were nearly but not exactly those which are now called (sometimes Napierian, but more usually) hyperbolic logarithms—those to the base e; and that the change to the base 10 (the great step by which the invention was perfected for the object in view) was indicated by Napier but actually made by Henry Briggs, afterwards Savilian Professor at Oxford (d. 1630). But it is the hyperbolic logarithm which is mathematically important. The direct function e^x or exp. x, which has for its inverse the hyperbolic logarithm, presented itself, but not in a prominent way. Tables were calculated of the logarithms of numbers, and of those of the trigonometrical functions.

The circular functions and the logarithm were thus invented each for a practical purpose, separately and without any proper connection with each other. The functions are connected through the theory of imaginaries and form together a group of the utmost importance throughout mathematics: but this is mathematical theory; the obligation of mathematics is for the discovery of the functions.

Forms of spirals presented themselves in Greek architecture, and the curves were considered mathematically by Archimedes; the Greek geometers invented some other curves, more or less interesting, but recondite enough in their origin. A curve which might have presented itself to anybody, that described by a point in the circumference of a rolling carriage-wheel, was first noticed by Mersenne in 1615, and is the curve afterwards considered by Roberval, Pascal, and others under the name of the Roulette, otherwise the cycloid. Pascal (1623–1662) wrote at the age of seventeen his 'Essais pour les Coniques' in seven short pages, full of new views on these curves, and in which he gives, in a paragraph of eight lines, his theorem of the inscribed hexagon.

Kepler (1571–1630) by his empirical determination of the laws of planetary motion, brought into connection with astronomy one of the forms of conic, the ellipse, and established a foundation for the theory of gravitation. Contemporary with him for most of his life, we have Galileo (1564–1642), the founder of the science of dynamics; and closely following upon Galileo we have Isaac Newton (1643–1727): the 'Philosophiæ naturalis Principia Mathematica' known as the 'Principia' was first published in 1687.

The physical, statical, or dynamical questions which presented themselves before the publication of the 'Principia' were of no particular mathematical difficulty, but it is quite otherwise with the crowd of interesting questions arising out of the theory of gravitation, and which, in becoming the subject of mathematical investigation, have contributed very much to the advance of mathematics. We have the problem of two bodies, or what is the same thing, that of the motion of a particle about a fixed centre of force, for any law of force; we have also the (mathematically very interesting) problem of the motion of a body attracted to two or more fixed centres of force; then, next preceding that of the actual solar system—the problem of three bodies; this has ever been and is far beyond the power of mathematics, and it is in the lunar and planetary theories replaced by what is mathematically a different problem, that of the motion of a body under the action of a principal central force and a disturbing force: or (in one mode of treatment) by the problem of disturbed elliptic motion. I would remark that we have here an instance in which an astronomical fact, the observed slow variation of the orbit of a planet, has directly suggested a mathematical method, applied to other dynamical problems, and which is the basis of very extensive modern investigations in regard to systems of differential equations. Again, immediately arising out of the theory of gravitation, we have the problem of finding the attraction of a solid body of any given form upon a particle, solved by Newton in the case of a homogeneous sphere, but which is far more difficult in the next succeeding cases of the spheroid of revolution (very ably treated by Maclaurin) and of the ellipsoid of three unequal axes: there is perhaps no problem of mathematics which has been treated by as great a variety of methods, or has given rise to so much interesting investigation as this last problem of the attraction of an ellipsoid upon an interior or exterior point. It was a dynamical problem, that of vibrating strings, by which Lagrange was led to the theory of the representation of a function as the sum of a series of multiple sines and cosines; and connected with this we have the expansions in terms of Legendre's functions P_n, suggested to him by the question just referred to of the attraction of an ellipsoid; the subsequent investigations of Laplace on the attractions of bodies differing slightly from the sphere led to the functions of two variables called Laplace's functions. I have been speaking of ellipsoids, but the general theory is that of attractions, which has become a very wide branch of modern mathematics; associated with it we have in particular the names of Gauss, Lejeune-Dirichlet, and Green; and I must not omit to mention that the theory is now one relating to n-dimensional space. Another great problem of celestial mechanics, that of the motion of the earth about its centre of gravity, in the most simple case, that of a body not acted upon by any forces, is a very interesting one in the mathematical point of view.

I may mention a few other instances where a practical or physical question has connected itself with the development of mathematical theory. I have spoken of two map projections—the stereographic, dating from Ptolemy; and Mercator's projection, invented by Edward Wright about the year 1600: each of these, as a particular case of the orthomorphic projection, belongs to the theory of the geometrical representation of an imaginary variable. I have spoken also of perspective, and of the representation of solid figures employed in Monge's descriptive geometry. Monge, it is well known, is the author of the geometrical theory of the curvature of surfaces and of curves of curvature: he was led to this theory by a problem of earthwork; from a given area, covered with earth of uniform thickness, to carry the earth and distribute it over an equal given area, with the least amount of cartage. For the solution of the corresponding problem in solid geometry he had to consider the intersecting normals of a surface, and so arrived at the curves of curvature. (See his 'Mémoire sur les Déblais et les Remblais,' Mem. de l'Acad., 1781). The normals of a surface are, again, a particular case of a doubly infinite system of lines, and are so connected with the modern theories of congruences and complexes.

The undulatory theory of light led to Fresnel's wave-surface, a surface of the fourth order, by far the most interesting one which had then presented itself. A geometrical property of this surface, that of having tangent planes each touching it along a plane curve (in fact, a circle), gave to Sir W. R. Hamilton the theory of conical refraction. The wave-surface is now regarded in geometry as a particular case of Kummer's quartic surface, with sixteen conical points and sixteen singular tangent planes.

My imperfect acquaintance as well with the mathematics as the physics prevents me from speaking of the benefits which the theory of Partial Differential Equations has received from the hydrodynamical theory of vortex motion, and from the great physical theories of heat, electricity, magnetism, and energy.

It is difficult to give an idea of the vast extent of modern mathematics. The word "extent" is not the right one: I mean extent crowded with beautiful detail —not an extent of mere uniformity such as an objectless plain, but of a tract of beautiful country seen at first in the distance, but which will bear to be rambled through and studied in every detail of hillside and valley, stream, rock, wood, and flower. But, as for anything else, so for a mathematical theory—beauty can be perceived, but not explained. As for mere extent, I might illustrate this by speaking of the dates at which some of the great extensions have been made in several branches of mathematical science.

In the address as written I speak at considerable length of the extensions in geometry since the time of Descartes, and in other specified subjects since the commencement of the century. These subjects are the general theory of the function of an imaginary variable; the leading known functions—viz., the elliptic and single theta functions, and the Abelian, and multiple theta functions; the theory of equations, and the theory of numbers. I refer also to some theories outside of ordinary mathematics, the multiple algebra, or linear associative algebra of the late Benjamin Pierce, the theory of Argand Warren and Peacock of imaginaries in plane geometry, Sir W. R. Hamilton's quaternions, Clifford's theory of biquaternions, and the theories developed by Grassmann's 'Ausdehnungslehre,' with recent extensions thereof to non-Euclidian space by Mr. Homersham Cox; also Boole's mathematical logic, and a work connected with logic, but which is primarily mathematical and of the highest importance—Schubert's 'Abzählende Geometrie' (1878); and I remark that all this in regard to theories outside of ordinary mathematics is still on the text of the vast extent of modern mathematics.

In conclusion I would say that mathematics have steadily advanced from the time of the Greek geometers. Nothing is lost or wasted; the achievements of Euclid, Archimedes, and Apollonius are as admirable now as they were in their own days. Descartes' method of coordinates is a possession for ever. But mathematics have never been cultivated more zealously and diligently, or with greater success, than in this century—in the last half of it, or at the present time: the advances made have been enormous, the actual field is boundless, the future full of hope. In regard to pure mathematics we may most confidently say—

"Yet I doubt not through the ages one increasing purpose runs,
And the thoughts of men are widened with the process of the suns."

OPINIONS OF THE PRESS UPON THE SUBJECT OF PROFESSOR ATTFIELD'S ADDRESS.

From the *Lancet*, September 22.

"It would be difficult to over-estimate the importance of the subject chosen by Professor Attfield as the theme of the able Presidential Address delivered at Southport on Tuesday to the members of the British Pharmaceutical Conference. The question of the relations of the State to pharmacy and of the supply of drugs to the public is of vital importance not only to the pharmacist, but to the physician. That matters in the pharmaceutical world are fast approaching a crisis is only too obvious; so little protection is now afforded to chemists and druggists that their very existence is endangered. The Act of 1868 decrees that no person shall practise pharmacy without passing a State examination and having his name enrolled on the Register. The provisions of this Act are unfortunately little better than a dead letter, and for years past they have been systematically evaded. The custom which long existed in country districts of allowing the general shopkeeper to sell a few of the commoner drugs has gradually extended and developed, until now medicinal compounds of all kinds are openly retailed by grocers, hairdressers, chandlers, confectioners, drapers, and a host of other unqualified individuals. Indeed, in many cases completely furnished shops, undistinguishable in appearance from those of registered chemists and druggists, are opened by mere distributors of drugs who have no knowledge of the nature of the dangerous articles they sell, and who have no sense of the responsibility of their position. These sham chemists and druggists keep everything the properly qualified chemist and druggist is allowed to sell, excepting only a few of the more virulent poisons scheduled in the Pharmacy Act. The result is that the public are supplied with untrustworthy medicines, and medical men have no guarantee that their prescriptions are accurately dispensed, or that pure drugs are employed for the purpose. It must be remembered that whereas purchasers of food are more or less protected from the purchase of bad food by their personal power of judging of its quality, purchasers of drugs cannot be protected from the purchase of bad drugs by any personal power of judging of their quality. Even the aid which purchasers of food can invoke from officials under the Acts relating to adulteration cannot be obtained in the case of medicines, for Nature yields drugs which vary much in quality, and analysts are not as a rule sufficiently familiar with the varying standards of the many medicinal articles comprehended under the term 'materia medica' to act in the interests of the public.

"The remedy for this unsatisfactory state of affairs may, according to Professor Attfield, be summed up in one word—'protection.' Where the health of the public is at stake, and where the public cannot protect themselves, an exception to the rule of free trade is not only justifiable, but is imperatively demanded. The law already refuses to permit the unrestricted sale of certain drugs. The only question is where the limit of exception should be fixed. It is contended that the lines should encircle all poisons, and that they should one and and all be excluded from the area of free trade. This involves no new principle; all that is necessary is an extension of the spirit and letter of the Pharmacy Act. At present only about a score of substances are deemed poisonous; but if the list were considerably extended it would afford protection to the public, and would restore to the pharmacist those functions and duties which he is best fitted to perform. . . .

"Eliminate special technical knowledge from pharmacy, and let drugs be sold by any or every shopkeeper, and the public will have no guarantee that they are not supplied with drugs fair in appearance to the untrained eye, but in reality worthless; drugs which once perhaps were of good quality, but which, without altering in appearance, have become spoilt by age; medicines weaker than they should be, medicines stronger than they should be; poisonous fluids for external application not properly distinguished from those for internal administration; indeed, the public will have no guarantee that they are not supplied with the wrong medicine altogether."

From the *Medical Press and Circular*, September 26.

"It is not at all a new conviction that Professor Attfield expressed before the Pharmaceutical Conference at Southport last week, to the effect that protection is the only remedy against indiscriminate drug dealing. For a long time past, not the professions only of medicine and pharmacy have recognized the paramount necessity of some decisive dealing with free trade in poisonous commodities, but common-sense economists and observant individuals of every class interested in preserving life and health have arrived at conclusions which mainly agree with those so ably and eloquently uttered by the President of the Conference above referred to. But while this is undoubtedly true, it must not be too readily assumed that the inferences and arguments advanced by Dr. Attfield are unanswerable reasons in proof of the need for reform, although the prime objection formulated by him, that, namely, public interest and public safety demanded the distribution of dangerous articles of consumption by trained and competent dealers, will find ready and universal acceptance.

"As the head and representative for the time being of the pharmacists and druggists of this country, Professor Attfield has naturally felt it incumbent on him to state the case of his clients in the most forcible manner possible. He had to face the introvertible fact of drug dealing by any and everybody who chooses to enter into the trade relations of chemists and its open indulgence by multitudes of shopkeepers who possess no special knowledge or licence entitling them to so trade, and that this wholesale competition is rapidly destroying the incomes enjoyed by legally qualified and registered pharmaceutists. Rightly enough, too, he argues that the transference of such trading from educated chemists to shopkeepers ignorant of the qualities and appearance of the articles they deal in, is attended with serious danger and inconvenience to the community, the members of which are entirely dependent on the protection the State affords them in respect to the immunity they obtain from being dosed with improper or injurious substances. The fault lies principally, not with the traders themselves, whether ordinary shopkeepers or registered chemists, but with the characteristic inefficiency of the Drugs Act of 1868, which, while forbidding unqualified persons to assume the *title* of chemist and druggist, in no way interferes with their assuming the *functions* they discharge, save and excepting only the sale of a few scheduled poisons. No one, we repeat, will question the existence of the mischief complained of, or fail to agree that amendment of the legislation which permits it is called for; but to the grounds on which Dr. Attfield defends the cause he is called on to plead, exception must in more than one instance be taken.

"The public has long complained of the exorbitant charges made by chemists for the medicines they dispense from prescriptions, and in recent years advantage has readily been taken of opportunities afforded at co-operative stores and elsewhere for getting the dispensing more cheaply performed. It is quite probable that this *has* done much to reduce the incomes made by the chemists, etc. Dr. Attfield, accepting the fact, goes on to insist that it is wrong to expect an educated and registered pharmacist to dispense for the same remuneration as a draper's or a grocer's services can command, the ground taken being that the former are *professional men*. The advice is then given to every chemist to denominate the charge for a bottle of medicine as his *fee*; and herein he is, we venture to think, guilty of an error which, in principle at any rate, pervades his whole reasoning. He contends that, inasmuch as the chemist must precede registration by a definite period of study, and conclude the latter by an examination which tests his fitness to be a dispenser, that therefore he is placed at once on a level with the professors of medicine and law. We do not wish to discuss how far the assumption could be maintained, but we do desire to point out a radical distinction between doctors and chemists, a distinction Dr. Attfield has apparently forgotten. The doctor receives a fee for his opinion and directions (including prescription) to his patient, and—omitting for the moment home prescribers —no transfer of material from practitioner to patient precedes the payment of the former. The chemist, on the contrary, receives payment for the articles he sells, with a percentage for the trouble he is at and the knowledge he displays in arranging them in the particular manner required by his customer. To call his remuneration a *fee* would be at once to deprive the term of all special signification, for as much justice would be in the demand of the hairdresser to be *feed* for cutting one's hair skilfully, or of the grocer for tying up one's tea neatly, or of the tinker for mending one's tea-kettle deftly. Should the proposal made by the President of the Pharmaceutical Conference be really carried out and the chemist insist on being paid a *fee* for his dispensing skill, then must a distinction be drawn between the medicine dispensed and the dispensing process, and each charged *pro ratâ*. Thus we may come yet to see a chemist's account made up of items after this fashion: 'Medicine 3*d*., dispensing ditto 1*s*. 3*d*.,' and so on, an absurdity that could harm none so much as the pharmacists themselves.

"It is of course right and proper for Dr. Attfield to seek to elevate the class of pharmacists as much as possible; but such advice as he gives them in respect to fees can hardly help their aspirations. So long as the chemist is in spirit a mere dealer in toffee, toothbrushes, and brick-dust, who dispenses medicine and sells drugs, he will never occupy a higher place in the public estimation than at present. Professional aspirations are not concordant with the wholesale dealing to which even the West-end chemists referred to by Dr. Attfield are given, and which detracts sadly from the ideal bearing that is sadly needed to raise the tone of chemists. They have not hesitated in the past to seek returns out of all proportion to the work done, and they must not be surprised if the public has seized on means, to its own detriment unfortunately, of obtaining its medicine at a less ruinous expenditure.

"There is also one point particularly on which medical men are fairly entitled to express an opinion adverse to chemists. The term 'prescribing chemist' is now so familiar that it would probably be difficult to name a member of the Pharmaceutical Society who does not deserve to have it applied to him. Dr. Attfield, it is true, attempts a sort of apology for this practice, but his attempt must be, even to himself, very unsatisfactory. He says that the chemist only temporarily treats an applicant for relief, always directing him to a qualified practitioner. We regret to say we have frequently seen this counter-practice in progress, but never have we been fortunate enough to hear such advice given as that Dr. Attfield describes. Only recently an instance showing the gross carelessness and ignorance of chemists came within our knowledge; it was in a large West-end chemist's: a girl came into the shop, and going to the nearest assistant, complained of sore-throat, and asked for 'something to cure it.' Incredible as it seems, this assistant, without examination of any kind, straightway gave the applicant a bottle of mixture—presumably chlorate of potash—with which he told her to gargle the mouth frequently, and swallow the gargle at the end. Surely if ever there was a case for medical treatment this was one; but no hint of the need of further advice was given; nor do we believe it is with anything like the frequency Dr. Attfield suggests.

"We could wish to write at greater length on what is, notwithstanding that we do not agree with its whole conclusions, a most interesting and important address. With its main demand—that for amendment of the Pharmacy Acts—we most cordially sympathize. That the dejected state of pharmacy which it describes really exists we do not for a moment doubt; but we do doubt whether Dr. Attfield has attacked the problem on the side most likely to be breached successfully. He tells chemists to claim the right to call the price of the things they sell *fees*. We tell them to make themselves worthier to be regarded as something better than the mere tradesmen that most of them now are. To this end they can strive without external aid, and the profession of medicine will most willingly co-operate with them in the endeavour. But pharmacists can never be rivals of doctors, even on the score of professional status; they are the complements of physicians, and the interests of the latter no less than of the public that both serve are intimately bound up in the success of the movement so ably advocated by the exponent of the pharmacy of the future."

From the *Medical Times and Gazette*, September 22.

"Dr. Attfield's address contains a large amount of carefully gathered information, and deserves to be thoughtfully read by everyone. In the most part of what he says we entirely agree with him; but unless the public at large can be seriously aroused to a recognition of the evils he points out, it will be to the last degree improbable that the present Government will trouble themselves about the matter."

From the *Daily Chronicle*, September 19.

"Professor Attfield, in his presidential address at the British Pharmaceutical Conference, at Southport, yesterday, took a rather gloomy view of the commercial prospects of the registered dispensers of drugs. As a body, they have no reason to repose implicit confidence in the virtue of Acts of Parliament. The Pharmacy Act of 1868, which everybody expected would create a valuable monopoly for qualified chemists and druggists, has had the very contrary effect. While it has imposed upon them the necessity of affording satisfactory proof of their fitness to distribute the 'perilous stuff' in which they deal, it has given them no protection against the competition of unqualified men who, 'bold in the practice of mistaken rules,' dispense, prescribe, 'and call their masters fools.' The Act merely provided that the title of 'chemist and druggist' could not be legally assumed by unexamined or unregistered men. There is nothing, however, to prevent such persons trading as chemists and druggists under some other title. Hence, many a man who has never troubled an official examiner in pharmacy thrives by 'pounding his poisoned poisons behind his crimson lights.' In addition to the sham chemists the duly registered members of the Pharmaceutical Society have to compete with grocers, oilmen, storesmen, and Jacks of all trades, who sell drugs of every description, with the exception of a few prohibited poisons. As Professor Attfield points out, however, nearly all drugs are poisons, more or or less, and there is as much difference in the quality of the commonest kind as there is in the quality of any other marketable commodities. It is an easy matter for the dealer in bad drugs to undersell the vendor of those of a genuine potency, and the worst of it is the public are quite unable to judge of the goodness or badness of the specifics included in the category of the British Pharmacopœia. To be able to do this requires the professional knowledge of which the properly qualified chemist and druggist has given proof. Dr. Attfield contends that the sale of all poisons should be exclusively entrusted to registered pharmaceutists. As the Pharmacy Act was passed for the protection of the public against the dangers arising from careless dispensing and the sale of worthless drugs by ignorant vendors, and as the Act has failed to ensure this protection, an amendment of it in the direction indicated by the President of the Pharmaceutical Conference is evidently needed."

From the *Morning Advertiser*, September 21.

"With many points of Professor Attfield's address we are able to agree, but there are many other points which have to be criticized from a much broader standpoint than that upon which they were dealt with by the speaker. . . . The main proposition Professor Attfield laid down is sound enough, namely, that the chemist and druggist, having taken the pains to qualify himself for the sale of drugs by obtaining a certificate of competency, is entitled to charge for the articles in which he deals not only such a price as will carry with it a fair profit upon the cost, but as will remunerate him for the knowledge and experience he brings to bear upon his business. . . . By all means let us have any measures which may be deemed necessary in order to secure the public against fraud in what, after all, is the most important article of commerce after food. This security is afforded by the existence of qualified chemists, and those people who wish to make sure that the prescriptions of their physicians are accurately dispensed will doubtless avail themselves of the knowledge and skill of the qualified persons who hold certificates of competency. But there are many drugs in common sale which can do no harm to anybody, and to suggest that Parliament should place them in the hands of a small class of vendors is to attempt the reinstitution of protection in a manner directly contrary to the public interests. Why preparations of well-known specifics, such as cod liver oil, quinine, rhubarb, aloes, and ginger, should not be sold in the open market we utterly fail to see. Chemists and druggists are sufficiently protected in the matter of the more dangerous drugs, such as poisons, narcotics, opiates, and so forth, and by their monopoly of the dispensing of prescriptions. No one in his senses who requires a dangerous drug, or an accurately-compounded prescription, would ever dream of going to anybody but a properly qualified chemist, whereas there is no need of the skilled retailer for the sale of Cockle's pills. That is the distinction we draw between the two cases. There are drugs which any man may sell without any possibility of danger to the public, and there are other drugs which can only be sold by persons familiar with their nature: and in the ordinary course of things the latter class of drugs are those for which people would naturally go to a qualified chemist."

From the *Morning Post*, September 20.

"The introductory address delivered at the twentieth annual meeting of the British Pharmaceutical Conference at Southport on Tuesday by the President, Professor Attfield, established the fact that a serious breach has occurred in the relationship of the State to Pharmacy, and that unless legislation be speedily undertaken the professional practice of pharmacy is in danger of complete extinction in many rural districts. . . . The doctrine of free trade in drugs, which some persons advocate, runs on curiously parallel lines with the general principles of so-called free trade by which the commercial affairs of this country are regulated, and its operation presents equally anomalous results. The British producer is compelled to fight his foreign competitors, even in British markets, with his hands tied; and in like manner the registered pharmacist, after being required to undergo a special training and pass a State examination, is exposed to the competition of traders who are allowed to practise his profession without having incurred the trouble and expense of qualifying for it. Drugs of all kinds, simple and compound, are being indiscriminately stored and sold by persons who, in many instances, are totally ignorant of their qualities and effects. In its bearing upon the position of the qualified chemist and druggist this, of itself, would constitute a grave evil calling for public attention, inasmuch as its inevitable result must be the extinction of his legitimate business in the smaller towns and remote country districts. But the matter has a wider importance as affecting the interests of the public at large. The purchaser of food is more or less adequately protected by his personal powers of judging of the quality of the article which he buys, but the rule does not hold good in regard to drugs. As Professor Attfield pointed out in his inaugural address, the maxim '*Caveat emptor*' cannot apply in this case, inasmuch as the purchaser does not possess the requisite knowledge to enable him to beware. It is to be feared that if the worthless or partially spoilt drugs that are frequently exposed for sale in the large wholesale markets could be traced to their ultimate destinations the truth of this remark would be fully established. Parliament has decreed that in a matter of so much importance to the public health as the supply of pure and reliable medicines the public shall be protected by requiring the dealer to give satisfactory proof of his knowledge of their properties and uses. That that protection should have been rendered valueless by a flaw in the enactment needs only to be demonstrated to insure the early attention of the Legislature. Whether the remedy recommended to the Pharmaceutical Conference—viz., to render illegal the retail sale of the simple and compound drugs of the British Pharmacopœia by any but registered chemists and druggists or medical practitioners—is not too drastic in so far as it affects the vending of patent medicines may be open to doubt, but it has at all events the double merit of simplicity and thorough efficiency."

From the *Globe, September* 19.

"Professor Attfield's address at the opening of the Pharmaceutical Conference draws attention to a subject whose importance can hardly be over-estimated. Have the public any guarantee, when they take a prescription to the chemist to be made up, or when they purchase drugs on their own account, that the practitioner at the counter understands his business? Practically, says Dr. Attfield, none at all. The Act of 1868 provides that no man shall call himself a chemist and druggist unless he has passed an examination and been duly registered. But, unfortunately, it is the name only that is forbidden, and not the calling. Any man is at liberty to hang a red lamp before his door, and to fill his window with those magnificent coloured bottles which have been the sign of the apothecary's trade from time out of mind. Not one person in ten who resorts, thus attracted, to the shop, thinks of asking to see the proprietor's qualification, and as a matter of fact prescriptions are made up and the most dangerous drugs dispensed, except only some few poisons which are scheduled in the Pharmacy Act, by barbers, booksellers, chandlers, confectioners, oilmen, publicans, stationers, tobacconists, and wine merchants. One consequence of this is that the qualified dispenser, who has incurred considerable expense in obtaining his professional knowledge and skill, is exposed to unfair competition, and is in danger of being driven out of the field altogether. It seems, indeed, that the number of registered pharmacists is actually on the decline. The interest of the public in finding a remedy for this state of things is not, however, less than that of the pharmaceutical profession itself. If the practice of pharmacy by qualified men becomes generally unremunerative, it will fall entirely into the hands of ignorant shopkeepers and their assistants. What is required is, obviously, to alter the Act of 1868 so that it may fulfil the intention with which it was passed. The unregistered tradesman must not only be forbidden to assume the title of a druggist, but he must be effectually restrained from selling drugs."

From the *Bedfordshire Times and Independent*, Sept. 22.

"There is some ground for the Professor's protest; but we question if he will speedily obtain a parliamentary recognition of his principle 'that the method which ought to have been adopted was that of rendering illegal the retail sale of the simple and compound drugs of the Pharmacopoia (with certain exceptions) by any but registered chemists and druggists, with the saving of all rights to medical practitioners.' The simple and compound drugs of the Pharmacopœia make up a long list, and many of them are substances in common use. It is self-evident that no unqualified person ought to be allowed to dispense medical prescriptions. It is also undisputed that the sale of virulent poisons ought to be carefully controlled. So far as pharmacy is a 'profession'—whatever may be the exact meaning of that very elastic term—it ought to be restricted to specially educated practitioners. But the Professor himself admits that the sale of an ounce of rhubarb is a commercial transaction; and we cannot see that the incapacity of either vendor or vendee to judge of the purity of the rhubarb is a reason why the substance should be withdrawn from open trade. Must the cook go to the 'chemist and druggist' for many of the simple substances she now gets, without any trouble, of her grocer? The truth is the 'chemist and druggist' has been endeavouring to raise his business into a profession; and has discovered that one important part of his income comes—or rather came—from that class of transactions which are purely commercial, and in which the unlicensed shopkeeper and the co-operative storekeeper can compete with him. The Act of 1868 undoubtedly needs amending; but the public will not tolerate the 'raising a legal fence'—to use Professor Attfield's words—round the sale of the simple and compound drugs of the Pharmacopœia, except on condition that the Professor's 'certain exceptions' are very numerous. The list of prohibited poisons may well be increased; and the penalties for adulteration may also be made heavier and be more rigorously enforced. But it is not necessary to make a man spend years of preparatory study before he is qualified to sell an ounce of rhubarb or a dose of Epsom salts."

From the *Birmingham Daily Post*, September 20.

"Although Professor Attfield's strictures upon the Pharmacy Act of 1868, at the opening of the Pharmaceutical Conference, were naturally formulated from the point of view of the dispensing chemist, and directed primarily to the better protection of the trade interests of the body he was addressing, there was much in them to appeal to the sympathies of the general public.. Up to a certain point it may be conceded that the interests of chemists and the public are identical; and if it be true, as asserted, that the existing Act tolerates the sale of the most potent drugs in the Pharmacopœia by unqualified persons, we can cordially co-operate with the chemists in procuring its amendment. The Act provides, it seems, that no man shall call himself a chemist and druggist unless he has passed an examination and been duly registered; but, unfortunately, it is the name only that is protected, the business calling itself is practically open to anyone. In point of fact it is largely exercised, we are assured, by numbers of persons—such as barbers, booksellers, chandlers, confectioners, publicans, oilmen, and others, who have no qualifications whatever for the delicate and hazardous office they undertake, and hence, no doubt, the number of accidental poisonings and deaths through inadvertence, which annually swell the bills of mortality. Anybody, it seems, may hang a red lamp over his door, and decorate his window with globular bottles of coloured water with impunity, and providing only that he does not call himself a chemist and druggist, he may dispense over his counter all the poisons in his shop, and compete successfully against qualified druggists, who are handicapped by a long and expensive special training. The unfairness of this practice to the qualified chemist is a matter which he may be safely left to deal with, but the danger to the public involved is one which everybody must feel and resent. Unfortunately the evil is more obvious than the remedy. We cannot, as the chemists would probably wish, prohibit the dispensing of drugs of any kind by unlicensed or unqualified persons, for it is not easy to define what do and what do not possess medicinal virtues, and merely to prohibit the making-up of medical prescriptions by unqualified persons would still leave a large and dangerous field open to the enterprise of the unlicensed dispensers. Herbalists and oil and colour men daily dispose of numbers of botanical and chemical preparations possessing potent medicinal virtues, and it would be impossible to interfere with their business because they are not licensed dispensers. The only practicable remedy, we are afraid, is the slow one of public enlightenment, which might be a good deal assisted, perhaps, by the display of chemists' diplomas in some conspicuous part of the dispensary. If this were made a rule of the trade, the public would soon understand that the absence of the diploma meant the absence of the qualification, and would learn to carry their prescriptions elsewhere."

From the *Bradford Observer*, September 20.

"The drug trade, it appears, is in a bad way, so far at least as the professional dealers are concerned; and one of the chief reasons for this unpleasant phenomenon is said to be the extensive appropriation of the trade by those who had never undergone proper training. These unqualified dealers, we are told, sell inferior and adulterated drugs, to the injury of the public. The remedy proposed is to forbid sale of drugs by any but duly-examined and qualified pharmacists. Outsiders might be inclined to doubt whether this would afford absolute security against adulteration. Furthermore, it would be extremely difficult to define drugs in an Act of Parliament, and unreasonable to provide that in country districts no shopkeeper should be allowed to vend castor oil or senna or other simple medicines. Again, if only druggists are to sell medicines, the doctors might fairly demand in their turn that druggists who prescribe—as many of them do for poor customers—should be punishable. If the Legislature provides penalties for adulteration, and forbids the sale by unqualified persons of the more dangerous drugs, it goes as far as the pharmacists can reasonably expect."

From the *Liverpool Courier*, *September* 19.

"Everybody knows that the pharmaceutical chemist is not above extending his trade by storing his shop with articles not strictly within the requirements of the healing art. He trenches on many of the trades enumerated by the Professor, even dispensing the cordials which the publican believes belong to his domain. Then again the druggists have lent their countenance to the patent medicines, which certainly require no special skill to sell. This distribution of 'packed or packeted goods' is one of the means by which the druggists have parted with their business. These are the goods which are now sold in the great drapery and other stores at such low prices that the druggist cannot compete with them and live. It is clear that in this the public derive advantage. It may be assumed, as the skilled pharmaceutist is willing to sell patent medicines, proprietary preparations, and coated pills, that he considers them harmless, if not actually beneficial, and very strong argument will be needed to convince the public that they will benefit by paying the druggist a high price for the identical 'packed or packeted goods' which they can purchase from another tradesman for very much less. The case of drugs which are not packed is very different, and here the public, as well as the druggist, is in need of protection which the existing law does not afford. It must be recollected that, as Professor Attfield points out, 'nearly all drugs are poisonous more or less,' and it follows that nearly all drugs should be dispensed and sold by persons conversant with their properties, and not admitted within that area of free trade which has tended to injure the druggist while jeopardizing the health and lives of the people. . . . We are afraid that the pharmaceutist must not look to the Legislature for much protection against the free-trade spirit of the age. Unless the 'packed and packeted' drugs can be abolished, they must be prepared to see a large share of their trade in the hands of other people; but the public have a right to be protected against the unregistered dealers who vend poisonous drugs without knowing the dangerous qualities of what they dispense."

From the *Liverpool Daily Post*, September 20.

"Druggists are in a bad way. So, at least, says Professor Attfield, the President of the British Pharmaceutical Conference, which was lately held at Southport, and he has taken some pains to ascertain the fact. This is partly the result of causes against which neither druggist nor anyone else can grumble: the improvement in the public health, the diminished use of stimulants, the lessened confidence in drugs, the disposition to trust to fresh air and clean water, and to let Nature have her own way. But there is something more than this, and that something closely concerns the public. An Act of Parliament passed in 1868 provided that no one should after the end of that year take the title of chemist and druggist and practise under it without being duly examined by a board appointed for the purpose, and having his name entered on the roll of qualified persons. But what was to prevent unqualified persons who do not call themselves chemists and druggists from selling drugs? The Act does indeed schedule certain poisons as to be sold only by the qualified; but these constitute only a small part of the trade, and almost its whole extent lies open to the inroad of the uneducated shopkeeper. Anybody can sell patent medicines; which, duly authenticated by wrapper and stamp, are as safely bought at the draper's as at the druggist's. There are other preparations—not patented—prescriptions, in short, ready made up—which are practically in the same category. The wholesale druggist sells his goods as willingly to one shopkeeper as to another, if only the money is forthcoming. In a word, the Act of 1868 has failed in its purpose. It was intended to secure that the sale of drugs should be in the hands of competently educated persons. As a fact the public buys much of its physic anywhere, and has no guarantee of its quality.

"That druggists should, like other tradespeople, be exposed to sharp competition, with the inevitable result of lowering prices, is not of itself a grievance with which the public will greatly sympathize. But this is a matter in which genuineness of quality is of much more consequence than lowering of price. Few parents can have reared a family of children through the necessary sicknesses of early life, without some instructive, perhaps painful, experience of this kind. Some medicine has been prescribed which has conspicuously failed to produce its proper effect, till at last the discovery is made—well if it be not too late—that an incompetent druggist has either left out some important constituent in the prescription, or that the drug supplied has been of so inferior a quality as to be quite inefficacious. Physicians have many a tale to tell of the difficulty of having prescriptions which contain rare or costly ingredients properly made up, even in large towns, while in the country they are usually driven to compound them themselves. This state of things is, no doubt, aggravated by the facts which Professor Attfield adduces. Still, it is difficult to see what direction future legislation should take. It would be impossible to give a certain class of men a monopoly of the sale of simple drugs. Even if it were not, it is conceivable that qualified druggists might sell inferior drugs—inferior, perhaps, in original quality, inferior from long haunting of the shelves. You may make druggists in this way the guardians of the public health so far as physic is concerned, but who is to guard the guardians? After all, the public must look out for themselves in this matter. If they are so stupid as not to recognize the advantage of scientific training in their purveyors of medicine, and prefer to buy physic at their draper, it is difficult to say them nay. At the same time, with sensible people the best druggist will always have the best practice; and we do not know that excellence in any profession can have, or ought to want, any better guarantee than this."

From the *Manchester Courier*, September 20.

"The address delivered by Professor Attfield at the Pharmaceutical Conference ought to receive attention. It discloses a serious danger to which the public are exposed, and to remove which legislation has taken place. That the law affords, nevertheless, no real protection was abundantly demonstrated, and it is clearly of importance that something should be done for the purpose of remedying its defects. The Act provides that no person shall adopt the title of 'chemist and druggist' and practise under it unless he has been shown by examination to be properly qualified, and his name has been duly entered upon the Register. The law in that respect is said to be systematically evaded. Numbers of persons who possess no knowledge whatever of the nature of drugs are engaged in their sale to the public, the evasion of the law in their case being simply the omission of the title of 'chemist and druggist.' Their shop windows contain all the usual indications that the business of a chemist and druggist is carried on, but the announcement is not made in words, so that, technically, there is no punishable breach of the law. Professor Attfield states that drugs of nearly all kinds, simple and compound, are indiscriminately sold by unqualified persons, amongst them being barbers, booksellers, chandlers, confectioners, drapers, general dealers, grocers, herbalists, ironmongers, marine store dealers, oilmen, tailors, tobacconists, and others. The Professor did not mention in what form these several tradespeople supplied the public with drugs, and the probability is that they are in the form of patent medicines, or other concoctions with the composition or preparation of which the vendor, whether he be a barber or a chemist and druggist, has nothing to do. The fact that a grocer or other tradesman disposes of preparations of that kind may be injurious to the professional chemist and druggist, but his doing so makes him no more a chemist and druggist than the sale of tinned meat would constitute him a butcher. It may be, however, that something more than patented specifics are disposed of by the tradesmen named, and that the public are really exposed to serious danger owing to the want of that knowledge, on the dealer's part, of which the possession of the right to use the words 'chemist and druggist' is a guarantee. Professor Attfield says that drugs are sometimes sold, by persons who are not chemists and druggists, at cost price, or very nearly cost price, 'as mere baits to catch customers,' and he contends that the sale of all drugs should be excluded from the area of free trade and confined to those who possess special knowledge in reference to them. It may be taken for granted, we suppose, that patent medicines are not examined by chemists and druggists before they sell them, and that, therefore, the public risk is as great when they are bought from a registered dealer as from a general tradesman; and if general tradesmen are to be prohibited by law from selling such 'drugs,' they may complain of the chemist and druggist being permitted to interfere with their particular line of business by the sale of cigars, sponges, soap, and other common commodities."

From the *Manchester Examiner and Times*, September 19.

"A good deal that Dr. Attfield said in regard to the public interest in this matter is undoubtedly true, and that admission may be made without involving an acceptance of the whole of his conclusion that the Pharmacy Act should be extended in its spirit and letter to the case of tradesmen other than qualified chemists dealing in drugs. No doubt, as he says the public have no guarantee that they are not supplied with drugs 'fair in appearance to the untrained eye, but worthless to the trained eye of the druggist, drugs which once perhaps were of good quality, but which, without altering in appearance, have become spoilt by age.' It is not easy to see, nor does the address explain, how in such a case State machinery can supply a substitute for the salutary caution which the public is required to exercise for its own protection. It is well, however, that we should be made acquainted with the views of the Pharmaceutical Conference on this point. If they do not compel immediate agreement, they deserve to be considered. And the proposal of the President is that the list of medicinal substances treated as poisons under the Pharmacy Act should be considerably extended (with due regard to the rights of persons who would otherwise be prejudiced), so as to prevent the free vending of poisonous compounds by any other than men who have satisfied the examiners of their competency to deal in dangerous medicines."

Parliamentary and Law Proceedings.

THE ALLEGED SALE OF DEFECTIVE TINCTURE OF QUININE.

At the Marylebone Police Court, on Wednesday, Mrs. Jane Allchin, carrying on business as a chemist at 1A, Elizabeth Terrace, Hampstead, appeared in answer to an adjourned summons taken out by order of the Hampstead Vestry for selling 3 ounces of tincture of quinine not containing the proper quantity of sulphate of quinine, viz., 8 grains to the ounce.

Mr. Ricketts, solicitor, appeared to prosecute on behalf of the Vestry; Mr. Glaisyer, solicitor, appeared to defend on behalf of the Chemists and Druggists' Trade Association of Great Britain. The case was before the Court a fortnight ago, when Mr. Heisch, the analyst to the Vestry, certified that the sample of quinine which had been submitted to him contained 6·2 grains of sulphate of quinine per ounce. Professor Attfield, for the defence, gave evidence showing that by the process of analysis adopted by him he found 7½ grains per ounce of sulphate of quinine. In consequence of the conflict in the chemical evidence the magistrate, on the application of the defendant's solicitor, decided to send a sample to Somerset House to be reported on by the Government analysts.

On the resumption of the case, the certificate of the Somerset House authorities was read. It stated that the sample contained not less than 8 grains of sulphate of quinine.

Mr. Mansfield dismissed the summons.

Mr. Glaisyer asked for special costs, which Mr. Ricketts opposed.

Mr. Mansfield pointed out that the results of the three analysts all differed, and it was very difficult to know who was right. He should make no order as to costs.

Obituary.

We regret to have so soon to publish the death of another "Bell Scholar," in the person of Mr. George Frederick Gutheridge, Surgeon of the Royal Mail Steam-ship 'Severn,' who died of fever in the West Indies on the 6th of July, at the age of 27 years. Mr. Gutheridge held the Scholarship during the session of 1876–77.

Notice has also been received of the death of the following:—

On the 31st of August, Mr. David Imrie, Chemist and Druggist, Consett, Durham. Aged 74 years.

On the 2nd of September, Mr. John Cunliffe, Blackburn Street, Bolton. Aged 53 years.

On the 7th of September, Mr. Charles Joseph Hartley, Chemist and Druggist, New Malton, Yorkshire. Aged 69 years.

On the 7th of September, Mrs. Mary Stokes, Chemist and Druggist, Watery Lane, Birmingham. Aged 74 years.

On the 9th of September, Mr. William Kemsey Bourne, Chemist and Druggist, High Street, Lavenham. Aged 38 years.

On the 10th of September, Mr. Horace Watson, jun., Chemist and Druggist, Laceby, Grimsby. Aged 35 years. Mr. Watson had been an Associate of the Pharmaceutical Society since 1870.

On the 16th of September, Mr. William Augustine Pridmore Ellsum, Chemist and Druggist, High Street, Newcastle, Staffordshire. Aged 27 years.

On the 17th of September, Mr. Charles Row, Pharmaceutical Chemist, Fore Street, Devonport. Aged 79 years. Mr. Row was one of the oldest magistrates of Devonport, having been placed permanently on the Commission of Peace shortly after filling the office of Mayor in 1863. He had been a Member of the Pharmaceutical Society since 1853.

Correspondence.

⁂ *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Copies of the Conference Address.

Sir,—Several requests have been sent to me, by post and through other channels, for copies of the Conference Address, as a pamphlet, to be distributed by chemists and druggists to their friends or customers, and inquiries have been made as to cost. Now, the address is already in type for the 'Year-Book,' and it makes a twenty-eight page pamphlet; or, if some press notices be appended, a thirty-two page pamphlet. If my colleagues on the Executive permit a production at cost price, and I feel sure they will, a parcel of 50 could be sent from the printers, post paid, for about 4*s*. 6*d*.; 100, for about 7*s*., or larger numbers, carriage free, for about £3 per 1000. If intending distributors will let me know by or before next Wednesday morning's post, at 17, Bloomsbury Square, how many copies they desire to have, the action of the Committee will be much facilitated.

No doubt this is one method of making that appeal to "the great mass of the community" insisted upon as so desirable, by Mr. Schacht, at the Southport meeting. How far it will be adopted remains to be ascertained.

The Conference desired, I think, to present a covered copy of my two addresses to each member of the Houses of Parliament—and I possess a sufficient number of copies of last year's address for such a distribution to be effected.

But correspondents ask me, in addition, to promote the transmission of a copy of this year's address, with added extracts from the press notices, to every registered chemist and druggist; drawing his attention to what the Pharmaceutical Society has done and is doing in the direction of legislation, asking him to endeavour to enlist editors of local newspapers on our side on the general subject of "the future supply of drugs to the public," and requesting him to do what he can in this and other ways to obtain the support of local public opinion and to secure the favourable influence of his Parliamentary representatives. I only know of one difficulty in the way of this being done—cost. I did present a copy of last year's address to every non-member of the Conference on the Register of Chemists and Druggists, hoping I should thus pave the way to that invitation to membership which I knew would be issued by the Conference later on; hoping, also, that I should do good in other ways. The twelve thousand copies, including wrapping, addressing and postage, cost me over £60, and I am well satisfied with the results. But I did not myself contemplate doing anything of the kind this year.

Remembering the very considerable amount of support which pharmaceutical policy (on all fours with the public welfare) is now receiving from the press, if that half of the druggists of Great Britain who are outside all pharmaceutical organizations, and who, doing nothing for themselves, so frequently complain that those inside do nothing for them, will now effectively put their shoulder to the wheel, and if those inside, with generous earnestness, will do the same, the gods of the Legislature will probably only too gladly aid us, with the result that pharmacy will again advance and the health and welfare of the whole country be thereby promoted.

John Attfield.

Sophisticated (?) Oil of Cloves.

Sir,—In the issue of the 8th inst., you publish a note on the above subject, by Mr. Spencer, in which he infers that the oil of cloves examined by him was a "mixture of genuine oil of cloves with a compound of the creasol class, as the latter gives the same coloration with Fe_2Cl_6."

Allow me to call his attention to the statement made by Hanbury and Flückiger, that "eugenol is by far the prevailing constituent" of oil of cloves, and that "it (eugenol) belongs to the phenol class;" hence it is not surprising that he should have discovered a similar "sophistication" to that of Herr Bechurt's. Had his series of experiments included the oil of pimenta (likewise consisting largely of eugenol) exactly the same results would have been obtained with ferric chloride. Or had the expedient been adopted of distilling a small quantity of oil of cloves for comparison, a more vivid and more persistent green coloration would have been obtained by the treatment of an alcoholic solution of this oil than could be produced by the ordinary commercial samples.

At present it is to be feared that adulteration, if any, must be looked for in some other direction than that of one of the natural constituents of the oil.

"*Jumbo*."—Dec. aloes comp.

"*Inquirer*" (Ilfracombe).—(1) See Disp. Memo. 626, *Pharm. Journ.*, [3], xii., p. 719, and answer on p. 806. (2) One preparation ordered is not official. Such a change would occur and your explanation is probably the correct one. (3) The acid. gallic. should be finely powdered and will then be partially suspended by the solution of gum. A "shake the bottle" label should be used. The mixture becomes brown in keeping but should not be of that colour when dispensed. (4) We cannot furnish this information.

W. C.—The gallic acid should be rubbed to a very fine powder and suspended in the fluid. Use a "shake the bottle" label.

T. F. T.—On the addition of the acid. phos. dil. the mixture becomes cloudy and a precipitate falls, consisting for the most part probably of iron. Ferri cit. c. strychnia is not official and samples differ.

S. Carsian.—Rub the morphia hydrochlorate with a little mucilage; it will be suspended, not dissolved. Use a "shake the bottle" label.

"*Inquirer*."—The subject has been referred to several times. See note on "Explosive Mixture" (*Pharm. Journ.*, [3], vii., 1054) and reply.

G. S.—*Echium vulgare.*

J. A. H.—(1) Probably *Crepis virens*. (2) *Hieracium boreale*. (3) Probably *Thrincia hirta*. (4) *Hypochœris radicata*. (5) Probably *Leontodon autumnale*. (6) *Barbarea vulgaris*. If cotton wool be used it should be tied round the base of the stem. The plants could be named more easily if they were first carefully pressed in a book, and the flowers, fruit and radical and stem leaves sent.

"*Minor*."—(1) *Eupatorium cannabinum*. (2) *Astragalus glycyphyllos*. (3) *Lythrum Salicaria*. (4) *Cichorium Intybus*. (5) *Polygonum Convolvulus*. (6) *Knautia arvensis*.

J. C. Hyslop.—Probably laburnum (*Cytisus Laburnum*). The odour resembles that of liquorice and is frequent in leguminous plants.

W. Smith.—We are unacquainted with such a work.

"*Alpha*" is referred to text-books on the subject, and the rule relating to anonymous communications.

R. H. R.—(1) The Bill as it at present stands would require the engagement of a qualified assistant at each branch business. (2) We cannot recommend particular makers. (3) Labels are now printed at so low a rate that we do not think you would be able to print them yourself more cheaply.

E. B. M.—*Torilis anthriscus.*

H. O.—It is not "porous" in the sense in which the word is usually used.

Communications, Letters, etc., have been received from Dunstan, Umney, Wells, Stearns and Co., Brown, Hickman, Leay, Stevens, Foster, Quinlan, Dodd, Wilkinson, City, W. G. B.

INTRODUCTORY SESSIONAL ADDRESS

DELIVERED AT THE COMMENCEMENT OF THE FORTY-SECOND SESSION OF THE SCHOOL OF PHARMACY,

October 6, 1883.

BY MICHAEL FOSTER, M.A., M.D., LL.D., F.R.S.

Mr. PRESIDENT, when you asked me to say a few words on this occasion, I at once said, "Yes." My experience is that when you ask anybody anything they always do say "yes;" but having said "yes," I next began to wonder why you had asked me, and I came to the conclusion that it must be because you wished to have an address from an outsider. But, sir, I am not altogether an outsider as regards pharmacy, for in times past I have rolled pills, I have folded powders, and I have written in a legible, if not in a bold, hand the directions how they were to be taken. Besides that, I have the honour to be, not a real member, but an honorary member of your Society. Still I fancy I am so far outside you that my external character will give an adventitious value to anything which I may have to say.

Now, having said "yes," my next duty was to find out what I was to talk about, and knowing there would be a distribution of prizes, my mind kept running on examinations, and I fear the few words which I shall have to speak to you to-night will deal a good deal with examinations. I fear that I may appear in this respect like a ghost at a banquet; but I may appeal to those who have received your prizes this evening, that they may be gratified that I am taking them as the topic of my discourse, and I may also appeal to those who have been unsuccessful, that they may possibly find some consolation in what I have to say.

Now we use examinations, as far as I can understand, for two purposes. In the first place, we use examinations that we may take the result of those examinations as a stamp, as a mark, as a certificate. But a stamp, a certificate, a mark of what? I wish to look at the matter somewhat carefully, and I think, perhaps, I have some little right to speak on this subject, because as a young man, although examinations were not, if I may use the phrase, so "rife" in those days as they are now, I was a good deal examined. Indeed I look back to certain years of my life as being a kind of hurdle race in examinations. It seemed to me that I had no sooner cleared one examination than there was another ahead of me. Then when I grew a little older, for as we know Time brings about a whirligig, I got as it were my revenge, and instead of being an examin*ee* I became an examin*er*, and there was a time, from which I have happily escaped, when my friends told me that I was the most examining man in England. So that I think I have some right to speak on this point, and yet I feel compelled to say—and in this I recognize on this occasion my ghostly character—that the real thing of which the result of the examinations is the stamp and the certificate, is ability and skill in passing an examination. I do not think we can go surely farther than that.

Nevertheless, we may use the examination safely in an indirect way. The stupid man and the idle man will never acquire skill and ability in passing an examination; the industrious and the clever will easily show skill in passing an examination; and we may use an examination indirectly very safely as a pass examination to separate the industrious and the clever from the idle and the stupid. But we may even then make mistakes, and those mistakes become much more probable when we use the examination as a means of sorting out people from each other; when we pass from the pass examination to the competitive examination. We have no doubt that A. is cleverer in passing an examination than B., and in all probability A. will in future life be a better man, and prove a more real man than B. But that is not always the case; the examinations often fail us in that respect. Again and again I have known men whom I have been obliged to speak of as good examination men, who did not prove of great value in after life; again and again I have known men who have not done well in the examination room, who have been of enormous value in after years. And then modern refinements have increased our difficulties.

I do not know, sir, whether you are acquainted with the poems of that vigorous old dissenter, the illustrious author of 'Robinson Crusoe,' Daniel Defoe; but he begins one of them with these remarkable lines—

> "Wherever God erects a house of prayer,
> The Devil always builds a chapel there,
> And 'twill be found upon examination
> The latter has the larger congregation."

Now, sir, whenever an examination is instituted in order to select the fit persons for this or that there always arise a certain number of people who undertake to put a lad through that examination whether he be fit or not. There are certain names given to these persons; they are sometimes called "coaches," they are sometimes called "crammers," but the name of "coach" seems to me very significant We have an idea that the prize in an examination is given because in the race the lad arrives at the goal by the exercise of his own limbs, and that his speedy arrival at the goal is a test of the soundness of his mind and the strength of his limbs. But a "coach" takes him on his back, and lands him there; it is at his expense he is carried there, and his arrival there is a token not so much of the lad's ability, but of the "coach's" skill. I speak this advisedly, because I have had some experience of "coaches." I quite admit there are some "coaches" who gain their end by real teaching; but they have deserted their clan, they are no longer "coaches," but teachers. But all are not so, and in my experience as an examiner, I have been brought to the conclusion that coaching has now-a-days achieved the position of a fine art, that it is an occupation of life into which a great deal of energy is directed. As far as I understand, the "coach" when he takes to coaching pupils does not consider in the first place the nature of the study, but what he is pleased to call "the examiner's mind." He makes a study first of all of the examiners. He knows their whims; he knows their fancies; he learns what answers will, if I may say so in the presence of others who are like myself examiners, tickle them most, and he directs his efforts accordingly. Indeed, sir, I understand that some of these "coaches" who have a large number of pupils take on them the functions of a general. They marshal their forces, and I know very well that in one examination where the *vivâ voce* is of some importance, a "coach" has been in the habit of sending his weak, hopeless pupils in first to know what the style of the questions was in order that the hopeful pupils might benefit by the knowledge. This is an additional, and a very serious and important additional difficulty, in taking the results of an examination as really a stamp of the merit of the candidates who have passed the examination.

But happily there is another use of examinations, a more noble one, a use which I believe to be on the whole a greater one, and that is this, that whether there be "coaches" or not the lad who goes in for an examination in any subject must in some way or another learn something of the subject. The examination compels knowledge, and there are many of us who know that but for an examination into which perhaps we entered for some partly vainglorious purpose, for the mere reason of getting a certificate or winning a medal, we might never have got an introduction to a science or a knowledge which soon fascinated us, and to which we have become attached ever since. And I believe it is probable that a great deal of the work of science is first made attractive to men who are introduced into a branch which they are afterwards destined to adorn by an examination of which when they took it in hand they had no idea either of the value or of the bearing. They have gone to it frequently for purely business ends, like Saul the son of Kish, who for business matters went to seek his father's asses and found a crown. Very often they have gone in for a medal or a certificate, and in the end have found that which was better than either medal or certificate; they have found knowledge.

Now, you will gather from what I have said, that I regard examinations as like many other things in this world, mixed in nature, partly good and partly evil, and it seems to me that one great need of the present time is to take such steps as should minimize the evil and increase the good. Now, I will venture to propose to you a paradox. I believe that the evils of examinations may be diminished, and the good may be increased, by simply multiplying them. I think the evil of examinations lies a great deal in their formal character; in their being frequently one supreme effort which is made and is left. I am inclined to regard that examination as the worst where a lad after two or three years' study on a variety of subjects, is examined in all of them in the shortest space of time. For instance, in a certain university, the subjects are so many that, as a poor, disappointed, despairing student said to me, preparing for this examination is like driving a lot of pigs. You have no sooner got hold of one subject than the others are all abroad. The worst examination seems to me to be that in which a lad brings up a number of subjects, after a somewhat lengthy preparation, before a group of strange men, of whom he knows nothing, and who know nothing of him, and before whom, to the best of his ability, he there disgorges, if I may use the phrase, his knowledge in a few hours. I do not believe that that examination is one just either to the student, or, if I may say so, to the examiner. The best examination seems to me that kind of one which is carried out in a partial manner in the School of Science at South Kensington, and which, if fully developed, takes on somewhat of this form, that a lad having to study two, three, or four subjects does not attempt to drive them, so to speak, all abreast, but takes one, or at most two, and devotes his whole attention to that one or at most two. Then as he attends the lecture, and especially as he carries out the practical work belonging to the lecture, a note is now and again taken by the teacher of the progress which he makes, and any doubt which the teacher may have is remedied by frequent informal examinations. At the end of the course there is a formal examination undertaken by the teacher, or if you please, by the teacher with the help of an assessor, in order that things may be straight and square and above-board. But I am one of those who think that no one can judge of a lad's progress like the man who has actually taught him, the more formal examination becoming, as it were, the crown of the three or four or six months' work, and the position which he gains in that subject should go as so much to his credit for his final degree or certificate. Then he would turn with a full heart and free mind to another subject, and treat that in the same thorough, honest, straightforward way. That I believe would be a kind of examination against which a coach of the utmost ability would have no power whatever. But, you will say, it would assume the form of compulsory lectures. Now, in politics, and in the general conduct of life, I am opposed to compulsion. I am one of those who believe that the art of government consists in developing the free tendencies of the people, and not in manufacturing unnecessary restrictions; that the progress of government consists in the diminution rather than the increase of laws, and that the ideal government is that which in the end finds nothing to do. I am opposed to compulsion; but I venture to think that this course which I have sketched out to you would not be a series of compulsory lectures.

For I am as opposed as possible to mere compulsory lectures. I cannot, and never could see the good of making a lad sit in the back benches and read a novel, or carve his name on the desk, while the lecturer is doing his best to open up to him grand views of the science which he is teaching. These would not be compulsory lectures; but such a course would involve compulsory study, and that compulsion I think is necessary for the good of the individual as well as the good of the public, of which he is a part. I am opposed to compulsion, but I do not think such compulsion unjust, nor do I think that legislation meddlesome or unnecessarily restrictive which gives the public security concerning the sale of things which are becoming in their nature alarmingly dangerous, and more and more alarmingly dangerous every day; which are alarmingly dangerous utterly out of proportion to the knowledge of the people who have to use them. I believe that when all people are educated there need be no restriction on the sale of drugs or poisons; but opposed to all compulsion, on principle, I still must admit that this is a case where compulsion should intervene, and if that compulsion is to intervene, I think the compulsion should be complete. If security is to be offered, I think that security should be a real one, and not a fantastic one; and I am inclined to think that that security is not to be found in a rapid examination, however conscientiously and however ably conducted; but that such a security must be found in some such course of study as I have ventured to sketch out.

But I feel that I am trespassing now on somewhat dangerous ground. A young gentleman has of recent years acquired some notoriety by his—as it seems to me—somewhat crude handling of an old topic, "Is life worth living?" And I daresay it occurs to many to put the question: "Is the pharmacist's life so much worth having that you are ready to undergo all these examinations, and to sink the money which is involved in them?" I fancy I hear someone say, that if you attempt legislation of this kind, in your rude endeavours to increase public security you will simply overreach yourselves; that in attempting to make the gate of entrance straiter and more strait, you will simply swell the number of those who climb over the wall. I can imagine people saying, "We have spent so much money and so much time in acquiring the right to sell strychnia with our sovereign's approval. We wait for customers but they do not come, and in the end we find a faithless public buying it clandestinely and cheaply round the corner." This I admit is a grave and anxious matter, and one on which an outsider perhaps ought not to say much. But I would venture to remind you that this is a difficulty not confined to yourselves. My brethren, the doctors, have the same complaint. They say that if the stringency of medical examinations is to be increased in the future as it has been in the past the young gentlemen who have thus been made to sound all the depths of biological knowledge, and to equip themselves with the whole panoply of the healing art, will never stoop to the drudgery of village practice and that our country poor will be left to the mercies of unlicensed quacks. The same cry comes also from other departments of life. The engineers have the same cry. I hear of it, too, even in the army, and it has reached the farmers. Everywhere we hear this complaint, that this science, which has turned the world upside down, has come hither also. Now is it not because science is becoming an increasingly potent factor in the struggle for human life, and is making the struggle a closer and a bitterer one? The work of science is to enable the skilled few to do the work which is done, or which used to be done, by the unskilled many. It lengthens the arm of each man, but within an area it diminishes the number of those who can live within that area. It is tightening up the whole world. Everywhere science is making itself felt, and in many respects, maybe, the whole of life is becoming one brilliant examination in science, and, moreover, the standard is raised year by year.

Now it is no good striving against the inevitable. As the story of human life unfolds each passing stage has its charms, has its good and its ill; but you cannot hope to keep the good and let go the ill of each passing phase. There was a certain pleasure in the old savage life. It was very good to pitch one's tent where one liked without the dread of leases, of contracts, and builders' bills; but then there was hunger and thirst, and there was bloodshed ever at hand. And I dare say many of my brothers, the doctors, think it must have been pleasant in the old times when anyone who liked, without reference to the central body, could set himself up to cure or to kill any of his neighbours who pleased to entrust their bodies to him. And I dare say it seems to you it would be a pleasant time when any of you, having found a corner house vacant and being possessed of three large bottles of coloured fluid, could at once proceed to deal out poisons to your neighbours quite regardless of Major and Minor. But I take it that my brethren, the doctors, would be very loth, with all the charms of the past, to go back eighty years, and I take it that you, too, would be unwilling to wipe out the Pharmaceutical Society and all it means, and to go back forty years. But if you do not go back, neither can you stand still. Many of you, looking back forty years, might think it was a purely voluntary act, the undertaking to institute the Pharmaceutical Society and all it meant. But, in reality, your ancestors were carried on by the spirit of revolving things, and that same spirit must carry you on to do still further things, and it is far better for you to put yourselves in harmony with the necessary course of events—much better to put your shoulder to than against the wheel of fate.

Now let me in conclusion offer one word of consolation to those who, recognizing that impending changes are inevitable, still regard them with dread. For myself I do not from a pecuniary point of view fear that either our doctors or our pharmacists will become so superlatively educated that our country districts will be left without men to prescribe or men to dispense. I feel sure that the struggle for existence is getting far too sharp to leave any place of that kind vacant for any length of time. But some of you will say, "Yes, the places will be filled up, but they will be filled up by men far too good for them, men who will remain disappointed, and in this attempt to develop your profession you are only making efforts to increase the sum of human discontent." But these persons forget that in the first place discontent arises largely from comparisons, and as I said just now you are no worse off than other people.

All ranks are feeling the same pressure; everywhere the same place is being occupied by a better man. You will find that better men, like yourselves, are now occupying these country places in which I once rejoiced, Mr. President, but which I find are always spoken of in the terms which I have used this evening. Moreover, there is one other consolation, viz., that which you accuse of breeding this discontent goes far to take it away, for it is one of the happy features of the work of science in human life that while it is making closer and more bitter the struggle, sharpening the fight between man and man, it is at the same time opening out new capacities for enjoyment. You look back to the man who without any trouble could set up his shop where he pleased without any previous education, without any previous training; but you must remember that the life of such a man was in the vast majority of cases limited to his dinner and the tittle-tattle of the village. I feel sure that every one of you who has passed through these portals feels that there are new pleasures of life opened up to you, of which you knew nothing before you entered these doors, and I feel sure that you will leave them with the conclusion that though pounds, shillings and pence, are and must always be the framework of happiness, still that the pleasures of an instructed mind are the best and most lasting habiliments of that framework. The former are the dry bones and the skeleton of happiness, but it is the latter which breathe into them the breath of life and make life a reality, Depend upon it that the money which you spend on your examination in procuring your licence is not simply returned to you in that licence, is not simply returned to you in the more lucrative trade to which that may lead, but it comes back to you every day in the greater light and the greater pleasure which you have in knowing things. That is an element which you must fairly consider when you come to ask the question whether in the face of so many examinations, so much increasing study, and so much diminishing return, a pharmacist's life is worth having.

OPINIONS OF THE PRESS UPON THE SUBJECT OF PROFESSOR ATTFIELD'S ADDRESS.

From the *British Medical Journal*, September 29.

"Professor Attfield has made out a strong case in favour of an immediate amendment of the Pharmacy Act of 1868. In his opening address as President of the Pharmaceutical Conference, at Southport, he has clearly shown that the aim of the Act in question, namely, the proper supply to the public of trustworthy drugs by duly qualified persons, has not been generally accomplished. Although Dr. Attfield's cogent criticism of the Pharmacy Act was naturally formulated from the standpoint of the pharmaceutical chemist, and directed primarily towards the support of the authority of the Pharmaceutical Society and the protection of the trade interests of his auditors, his observations cannot fail to quicken the interest of the medical profession in the reforms he advocates, and to demonstrate to the general public the pressing need for more stringent regulation of the conditions under which they purchase their medicines. A general impression has hitherto prevailed that the Pharmacy Act prevented the sale of powerful drugs, or the dispensing of prescriptions, by any but properly educated and publicly authorized persons. Dr. Attfield authoritatively informs us that the public have really no reliable guarantee that the shopkeeper who sells drugs or undertakes the compounding of prescriptions is qualified for his responsible and hazardous work. The Pharmacy Act provides, it seems, that no man shall call himself a chemist and druggist unless he has passed certain examinations, and been duly registered. But, unfortunately, it is the name only that is protected, not the exercise of the calling; the business itself is left open to anyone, without let or hindrance, and the Pharmacy Act is practically a dead letter. Anybody, as the law at present stands, is at liberty to hang a red lamp over his door, and to fill his window with the orthodox bottles of coloured water; and providing only he does not incur penalty by calling himself a chemist and druggist, to sell drugs and poisons without restriction, and to "make up" prescriptions with impunity. This practice is grossly unfair to the honestly educated and duly certificated chemist, and it constitutes a grave and widespread public peril, which cannot be suffered to continue. Dr. Attfield assures us that drugs of nearly all kinds, simple and compound, are now being indiscriminately sold by unqualified persons; that it is a notorious fact that prescriptions are dispensed, and the most dangerous drugs supplied, except only some few poisons which are scheduled in the Pharmacy Act, by barbers, booksellers, chandlers, confectioners, drapers, general dealers, grocers, hairdressers, herbalists, ironmongers, marine-store dealers, oilmen, printers, publicans, stationers, storekeepers, tailors, tobacconists, toy-dealers and wine-merchants. The public can, more or less, judge of the quality of the food or raiment they purchase, but they cannot safely be left to protect themselves in the case of drugs. The failure of the Act has arisen from the adoption of a wrong method of protecting the public. A legal fence has been raised around a mere name. Experience has shown that the method that ought to have been adopted was that of rendering illegal the retail sale of the simple and compound drugs of the Pharmacopœia, with certain well-recognized exceptions, by any but registered chemists and druggists, with the saving of all rights to medical practitioners. As a remedy for the evils he described, Professor Attfield advocated an extension of the principle and letter of the Pharmacy Act. It is obviously necessary, both for public safety and for the protection of the qualified chemist, to amend the Act of 1868, so that it may really accomplish the purpose for which it was ostensibly passed. It is not sufficient that an unqualified and unregistered tradesman shall be prevented from assuming the name of chemist and druggist; he must also be effectually restrained from selling drugs and compounding medical prescriptions."

The Pharmaceutical Journal.

SATURDAY, OCTOBER 6, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE COMMENCEMENT OF A NEW SESSION.

THE past week has been a busy one in the medical and pharmaceutical schools of the metropolis. Lecture-halls and class-rooms, after a couple of months of comparative silence, have once more been enlivened by the footsteps of gathering students and have echoed to the sound of "Introductories," full of kindly words of encouragement and sage advice. Young men putting on, for the first time, the harness for work, will for a considerable time feel the stimulus of the prizes and laudations bestowed upon those who have been the most successful labourers in a past session; others who are resuming interrupted studies, and who are not so sanguine, perhaps, as in a previous session, as to the distinctions they may gain in their respective schools, but who are sobered and fitted for a steady and sustained effort by previous contact with the work and a clearer appreciation of the nature of the task that remains to be completed, will feel the impulse in a modified form. Considering what as a rule will be the ultimate object of the commencement or resumption of study in the schools it is safe to predicate that in the minds, if not upon the lips, of professors and pupils, one word will be perhaps unduly present, and that is "examination," for even the greatest purists among them, who would decry most vigorously the idea that examination should in the least degree lead the school, will recognize that examination is an ordeal that has to be passed. Notwithstanding this, if we may judge from the published reports, the word is markedly absent from the "introductory" addresses except in one instance, in which, however, it formed the text of a remarkably able discourse. We refer to the address delivered by Professor MICHAEL FOSTER, on Wednesday evening last, to an audience which thronged the lecture theatre in Bloomsbury Square.

The address is printed on another page, and will doubtless be read with pleasure by all interested in the subject. It is the outcome of the ripe experience of one who, as he quaintly puts it, was, as a young man, "a good deal examined," and who, when he grew a little older got as it were his revenge, and instead of remaining an examinee became an examiner. Therefore, it is of interest to notice that upon the evening of the day upon which the Council of the Pharmaceutical Society had mad another step towards securing the enforcement of a curriculum as a preliminary condition essential to passing the examination as to qualification for registration as a chemist and druggist, Professor FOSTER expressed to his audience of pharmacists *in esse* and *in posse* his deliberate opinion that "the real "thing of which the result of the examinations is "the stamp and the certificate is ability and skill in "passing an examaination," which might be used indirectly to separate the industrious and clever from the idle and stupid, but could not be trusted implicitly to do even that. The weak points of the examination system, and some of the evils that it entails, were graphically described and are generally recognized. As to the paradoxical remedy suggested by the speaker,—the multiplication of examinations as a means of minimizing the evils and increasing the good attendant upon them,—it is in accord, we believe, with the practice which has for some time past obtained in the school in Bloomsbury Square, where the Professors habitually test the progress made by the pupils and accustom them by *vivâ voce* examinations at frequent intervals to formulate the knowledge they have attained. But it seems evident that Professor FOSTER would go further than this and entrust the teacher with important functions in the pass-examinations of his own pupils. We presume that here he was speaking generally of the subject, and that he had in his mind merely the examinations upon which might be based a general certificate that the student had made good use of certain opportunities. We do not gather that he contemplated the introduction of such an innovation into the mode of conducting the examinations provided for in the Pharmacy Act, and indeed we may remark that the acceptance of certificates based upon examinations so conducted to the extent that the holder had gone satisfactorily through a prescribed curriculum has in the United States been found to be occasionally attended by inconveniences. But there can be no doubt as to the truth of the statement that no one can judge of a pupil's progress like the man who has taught him, and it would therefore seem desirable, if possible, to turn this capability to some account.

During the last three weeks pharmacists have perhaps to a greater degree than usual been made sensible of the wrongs that they endure—or at any rate fancy they endure—from unlicensed competitors, and they have enjoyed the luxury of an unusual amount of sympathy from the public press on the subject of their grievances. The experience has been probably to some extent enervating, if not demoralizing, and symptoms of this influence are to be seen in the tendency in some quarters to assume that the sole—or even the chief—recompense for the money and time sunk in the scientific training of a pharmacist is to be found in a limited protection from competition in the business of supplying medicines to the public.

Far be it from us to attempt to minimize in the slightest degree the claims which the pharmacist who has complied with the requirements of the law has upon the Legislature that the spirit of the law passed by it shall not be allowed to be evaded by unqualified pretenders. But there is nothing gained by indulging in Utopian dreams which are never likely to be realized, and it is necessary to recognize the conditions of life by which we are surrounded in order to obtain a clear perception of the good that is attainable. If there are any who feel that consideration of their wrongs during the last few weeks may have led to an undue relaxation we recommend them to read the straightforward manly words of Professor FOSTER in the latter part of his address, which should produce upon them an effect as bracing as a cold douche. As pointed out by the speaker, the time has passed when the influence of science was confined to what were termed the learned professions, and the education upon which the pharmacist is apt to base a claim for special consideration has become a necessity if he wishes to keep abreast of many of his customers in some of his special subjects.

The interest which was unflaggingly manifested during Professor FOSTER's address was sustained during the succeeding short but interesting ceremony of presenting the "Hanbury Medal" to Mr. JOHN ELIOT HOWARD. No words are necessary here to explain the nature of the services which Mr. HOWARD whilst indulging his love for scientific investigation has been enabled to render to mankind. Probably as long as cinchona bark remains an article of the materia medica the name of HOWARD will be associated with it. But it is especially interesting to learn that the labours of Mr. HOWARD in this direction were influenced to so large an extent by the lamented pharmacologist in memory of whom the medal was instituted.

THE AMERICAN PHARMACEUTICAL ASSOCIATION.

JUST a week previous to the meeting of the British Pharmaceutical Conference in Southport, —namely, on the 11th of September,—the thirty-first meeting of the American Pharmaceutical Association was commenced in a lecture hall connected with the Smithsonian Institution in the city of Washington. In respect to numbers the meeting would appear to have been a very successful one, no less than two hundred and fifty members having signed their names as being in attendance. The business proceedings extended over four days; but, as indicated in a notice which appeared in this Journal a few weeks since, they were by no means so incessant as to exclude festivities during that period. Indeed there was a manifest disposition on the part of the more industrious visitors to resent as excessive the demands made upon their time by the Entertainment Committee for feasting and visiting. It is known that some of the features of the meetings of this Association, such as the presentation of reports by permanent committees on legislation, the drug market, etc., are absent from those of the British Pharmaceutical Conference, and in some respects the scope of its operations is wider. But it must be admitted that apparently there is also a marked difference in the disposition to discuss at inordinate length and at unexpected moments matters of detail which in this country are left in the hands of the Executive to deal with. One result is that the proceedings in the American Association sometimes seem to lack the regular continuity to which the members of the Conference have become accustomed. It may be partly from this cause too, that the reading of practical and scientific papers, which in this country constitutes the chief occupation of the Conference, appears in the United States to be somewhat dependent upon circumstances; at any rate, notwithstanding the longer duration of the meeting, the number of papers read there is not usually so great.

From the report of the Committee on Legislation it appears that a law regulating the practice of pharmacy in the city of San Francisco has been repealed on the pretext that the constitution of California does not allow of the enactment of local laws, but the real motive is attributed to the disinclination on the part of some of the San Francisco druggists to pay an annual registration fee of one dollar. On the other hand a new Pharmacy Act has been passed in the State of Delaware, reserving to registered persons the right to conduct a pharmacy or store, or to sell, compound, or dispense medicines or poisons within the corporate limits of any town of five hundred inhabitants or more. An amended Act has also been passed in West Virginia. In addition, a Bill has been drafted, to be brought before the next Congress, under which, if it passed into law, the apothecaries in the United States army and navy would become commissioned officers, with the rank and pay respectively of second lieutenants of infantry in the army, and of ensigns in the navy. A resolution requesting the Committee to assist in securing legislation in this direction was subsequently passed by the Association. The yearly accession to the legislation affecting pharmacy, of one or more Acts that in hardly any case are identical in substance with those previously in existence, evidently furnishes material for considerable perplexity as to the exact position which pharmacists occupy in particular States, and the President of the Association expressed a strong opinion as to the desirability that Congress should pass a national Pharmacy Act to make a more uniform code of law for all the States. Another subject which was brought forward in the President's address was the sale by the United States Government of drugs and medicines that have been condemned by the drug examiners, and a resolution protesting against the reprehensible practice was afterwards passed. There were about fifteen papers read, and we hope to publish some of them in an early number.

In connection with the meeting of the Pharmaceutical Association, and immediately preceding it, a meeting was held which resulted in the organization of a National Retail Druggists' Association for the purpose of dealing with all questions of commercial importance to the trade. But, probably, the special *raison d'être* of this Association is the competition that exists in the United States, as in this country, in the selling of proprietary articles. A Committee was appointed to make an arrangement to secure the establishment of the "rebate plan," under which manufacturers of proprietary articles would sell their goods to those "jobbers" only who will agree not to supply them to retail dealers at a rebate price except upon receiving a written agreement that they shall not be sold below the marked retail prices.

The School of Pharmacy advertisement on another page will be found to contain information as to some important changes in connection with the Chemistry and Pharmacy Class that will come into operation in the session which has just commenced. The Class in Practical Dispensing, which under the management of Mr. Dimmock has proved such a success as to demand more teaching power, will have the advantage of the services of another accomplished pharmacist in Mr. Joseph Ince, who will henceforth be associated with Mr. Dimmock in conducting it. In addition, Mr. Wyndham R. Dunstan, who has for some time past assisted Dr. Redwood in the lecture room, has now been formally appointed Assistant Lecturer on Chemistry and Physics, and according to a statement made on Wednesday evening he will deliver some supplementary afternoon lectures.

* * *

At the meeting of Council on Wednesday last, upon the recommendation of the Benevolent Fund Committee, it was decided that there should be an election of Six Annuitants in December next, and a list of ten approved candidates was adopted.

* * *

As will be seen from a report which appears on p. 280, at a meeting of the executive committee of the British Pharmaceutical Conference, held on Wednesday last, it was resolved that it was desirable that the two Presidential Adresses delivered by Professor Attfield at Southampton and Southport should be brought under the notice of the members of both Houses of Parliament. The plan suggested is that, as far as possible, this should be done by persons residing in different parts of the country, who may be able to bring some personal influence to bear at the time of presenting the pamphlet, and communications upon the subject from those who are willing to undertake the duty are invited. It only remains to add that the arrangements foreshadowed by Professor Attfield in his letter on p. 260 last week have now been made, and that chemists and druggists wishing for copies of the Southport address for distribution may now obtain them at a price representing the cost of their production.

We understand that the papers on existing legislation relating to the sale of poisons, to which we referred on a recent occasion as likely to be brought before the National Association for the Promotion of Social Science, during its meeting at Huddersfield, will be read in the "Repression of Crime Section," on Monday morning next, the 8th inst.

* * *

At the recent meeting of the German Pharmaceutical Society, the question was broached as to the advisability of a more frequent issue of the official journal, the *Archiv der Pharmacie*. It was stated by the President that the subject had already been under the consideration of the Council, which had decided that the *Archiv* shall be issued twice instead of once a month, after the commencement of next year, if upon inquiry it be found that the consequent increase in the expenses would not be too great.

* * *

As the *Archiv der Pharmacie* resembles this Journal in that a copy is supplied free of cost to every member of the Association to which it belongs, it may be interesting to quote some figures as to that Journal from the published report. During the past year the number of copies printed monthly was 3150; of these 2802 were sent to members, the remainder representing the sales, stock, exchanges, etc. The gross cost of production was 18,066 marks, while on the other hand the receipts for sales and advertisements had amounted to 2578 marks; the net cost of suppling 2802 copies of the journal monthly to the members of the Association was therefore 15,488 marks.

* * *

At the recent half-yearly meeting of the Council of the Ontario College of Pharmacy it was decided to make an important change in respect to the *Canadian Pharmaceutical Journal*, which is the official organ of, and has hitherto been published by the College. The property in the Journal, together with all advantages accruing from its publication, has been made over to the Editor, Mr. E. B. Shuttleworth, for a term of five years, on the condition that for a minimum annual sum of seven hundred dollars he shall mail a free copy monthly to every member up to the number of seven hundred. Should this number be exceeded an extra sum of one dollar per annum is to be paid for each member in excess and similar payment is to be made for copies supplied to students and assistants connected with the College. The first number published under the new arrangement is printed on a page of larger size, and gives evidence on the part of the Editor of his intention to substantiate its claims to be "the organ of the Canadian drug trade."

* * *

A new work on Systematic Botany is now being published in Japan under the auspices of the Japanese Government. It is of folio size, and gives illustrations of the plants, apparently both wild and cultivated, growing in Japan. The first part contains illustrations of *Pæonia Moutan*, *Chimonanthus fragrans*, *Illicium anisatum*, var. *religiosum*, and several species of magnolia.

* * *

The first meeting of the Chemists' Assistants' Association in the new session will be held in University Chambers, 53, Conduit Street, on Wednesday evening, October 10, at 8.30 p.m., when the President will deliver his inaugural address.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, October 3, 1883.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Williams, Woolley and Young.

The minutes of the August meeting were read and confirmed.

The Pharmaceutical Conference.

The Vice-President, as one of the delegates appointed by the Council to attend the recent meeting of the Pharmaceutical Conference at Southport, wished to have the fact recorded that the meeting was in every respect a great success, whether regarded in its scientific or its social aspect, the number present being larger than on any previous occasion. Without going into the merits of the presidential address, the papers, or the discussions, of which members could judge for themselves by the report, he desired to express most strongly his personal appreciation of the manner in which every possible wish of the visitors to Southport was anticipated and provided for, and he regretted that there was no closing meeting at which expression could be formally made of what he was sure was the universal feeling amongst those who attended the Conference.

Mr. Savage said he thoroughly acquiesced in everything the Vice-President had said.

The President said it was very satisfactory to know that the meeting had been so successful. From what he had heard it seemed as if one result of the late Conference meeting would be to leave a good deal of work for this Council or some other body to do.

The Patents Act and the Medical Bill.

Vote of Thanks to Local Secretaries.

The President said it might perhaps be well to state briefly what had taken place with regard to certain legislative matters since the last meeting. In the case of the Patents Act, which originally contained a clause relative to the use of the royal arms in trade which had caused some alarm, the result of an interview he had had with Sir Thomas Farrer, was that an amended clause was suggested which the Council approved. This clause was moved by Sir John Lubbock, and ultimately became part of the Act. It might be satisfactory to the members and the trade to know that the law officer of the Crown, in reply to a question in the House, had stated that in its amended form the Bill would not interfere with the use of the royal arms in any way in which chemists and druggists would desire to use it. With regard to the Medical Acts Amendment Bill, it was stated by the Prime Minister, positively, up to almost the last moment that this Bill would be proceeded with, and it therefore became necessary to take action with reference to the amendment of the clauses relating to the revision of the British Pharmacopœia. As was now matter of history, the Bill was opposed by some sections of the medical profession and, ultimately, on August 22, it was withdrawn. It was some satisfaction, however, to know that the efforts of the Council and others would not be wasted, for he had every reason to believe that when the Bill again came before Parliament, some such clause as was desired, recognizing the claims of pharmacists to be associated with medical men in the revision of the Pharmacopœia, would be inserted.

The Vice-President remarked that the President had sacrificed a considerable portion of his holiday by remaining in town to watch over the interests of the Society, whilst Parliament remained in session.

Mr. Young thought the Society was much indebted to Mr. Symes for bringing forward the question of the royal arms, the original clause having caused great consternation in Scotland.

The President said it was a great satisfaction to him to find that the Council had been successful in its effort to get the clause amended, especially as the Society of Arts had previously moved in the same direction, but without effect.

Mr. Symes said he had been informed by one printer, not in a very large way of business, that the expense he would have been put to had the original clause stood would have been about £500; and this statement, which somewhat astonished him, was fully borne out by two other printers whom he consulted.

Mr. Hampson wished to add, with reference to the Medical Bill and the Pharmacopœia question, that he had learned from various sources that the influence exercised by members of the trade on their representatives in Parliament had been very great, and that they had received a very general acquiescence in the views they had presented. This would encourage them in their efforts in the future, and he believed that when the matter again came before a Government department there would be little difficulty in obtaining all that was required. He would move a vote of thanks to the Local Secretaries and others who had so greatly assisted the Council in the matter.

Mr. Borland corroborated what Mr. Hampson had said. He had had some correspondence with his own member, and received from him a most kind letter saying that he would support the prayer of the petition sent him when the occasion arose.

Mr. Bottle, Mr. Schacht and Mr. Symes also spoke in similar terms as to the kind manner in which their reports had been received by members of Parliament.

The Vice-President said he had been much struck with the assent which medical men had given to the idea that pharmacists should have a voice in the preparation of the Pharmacopœia when it was put before them.

Mr. Squire seconded the motion as to the vote of thanks proposed by Mr. Hampson, which was put and carried unanimously.

Elections.

MEMBERS.

Pharmaceutical Chemist.

William Lloyd Williams, of Buckley, having passed the Major examination and tendered his subscription for the current year, was elected a "Member" of the Society.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Cochrane, James ....Wishaw.
Jenner, Harry Albion ....St. Leonard's-on-Sea.
Macintyre, John ....North Berwick.
Parkes, Harry Charles............Weston-super-Mare.
Paterson, Alexander C. ....Douglas, Isle of Man.
Schofield, John William ....Rothbury.

ASSOCIATES.

The following, having passed the Minor examination and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Atkinson, Richard ....Penrith.
Harston, Charles Edward ......Lincoln.
Keeling, Arthur Gadsby.........Walthamstow.
Layng, Henry ....Brandon.
Shepard, William...................Newport (I.W.).
Whiston, Edmund ....Wolverhampton.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Baker, Alfred Henry Sanzen ...Gateshead.
Bowes, John William ....Pocklington.
Cowin, William Stephen.........Union Mills.
Greensit, John William ....Masham.
Hughes, John ....Aberystwith.
Johnson, Charles Ernest.........London.
Kirkup, George John ....Newcastle-on-Tyne.
Loeffler, George Berthold ......London.
McAllister, Robert D. S..........Helensburgh.
McKenzie, James...................Cullen.
Marshallsay, Richard Jeanes ...Wareham.
Roberts, Roderick ....Crickhowell.
Scarr, John ....Todmorden.
Stothert, Robert ....Blackburn.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

ADDITIONS TO THE REGISTER.

The Registrar reported that:—

Thomas Campbell McCormack, 19, St. Saviourgate, York;

Benjamin Death, 147, Charles Street, Stepney, London, E.; and

William Thomas Upfill, 74, Rodney Road, Walworth, London, S.E.,

having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been supported by duly qualified medical practitioners, their names had been placed on the Register.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee included the recommendation for the payment of various accounts, and also recommended that in the case of a pharmaceutical chemist, a fine of 10*s.* 6*d.* in commutation of arrears of subscription be received from him on re-admission to membership of the Society.

The motion for the adoption of the report having been moved and seconded, the Council went into committee to discuss the subject of payment of arrears, which occupied a considerable time.

Ultimately the VICE-PRESIDENT moved an amendment to the effect that the report of the Finance Committee be adopted, except that portion referring to the payment of arrears by a pharmaceutical chemist, and that the question of payment of fines for restorations be referred to the Library, Museum, Laboratory and House Committee.

Mr. SCHACHT said this was a very important addition to the amendment, and he thought an unfortunate one.

The PRESIDENT said the instructions were that the office was to use its discretion up to a certain point, and that all other cases were to be referred to the Finance Committee. That was the reason why this case had been submitted to the Committee.

Mr. SCHACHT said the Finance Committee had simply fulfilled its instructions in taking this case into consideration, and it had come to a conclusion upon it. If the Council refused to accept that conclusion it was of course open to it to do so, but it ought to be distinctly understood, and then if it were desired that the Finance Committee should have further instructions for its guidance in the future, a fresh motion should be made on the subject. As a member of the Finance Committee, it seemed to him a distinct affront to that Committee to reject its decision in this way.

The PRESIDENT remarked that the Vice-President had in the first place suggested that the matter should be sent back to the Finance Committee to be re-considered; but it was thought better that it should be referred, if at all, to the Library Committee.

After some further discussion, the amendment, leaving out the latter portion again referring the general principle to a Committee, was put and lost, and the original resolution was put, and carried by 10 votes to 7.

The VICE-PRESIDENT then moved that the general question of fines for restoration to membership be referred to the Library, Museum, Laboratory and House Committee for consideration, which was agreed to.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a former pharmaceutical chemist member, aged 70, who has had three previous grants.

£5 to a former pharmaceutical chemist member for forty years, aged 81. Applicant had a considerable grant in February last.

£5 to the widow of a pharmaceutical chemist and member, who has had two previous grants.

£10 to a pharmaceutical chemist and former member, aged 80.

£5 to the widow of a registered chemist and druggist, who has had two previous grants.

£5 to a registered chemist and druggist, out of employment and suffering from illness.

£10 to a registered chemist and druggist, aged 69, who has had two previous grants.

£10 to the widow of a registered chemist and druggist, aged 66.

£5 to the widow of a registered chemist and druggist and annuitant. Applicant has had two previous grants.

Two other applications had been deferred for further inquiries, and one had been rejected.

A suggestion for the apprenticing of one of the Isherwood orphans had been considered, and it was recommended that £10 for the payment of premium be placed in the hands of the Secretary, who should endeavour to obtain more favourable terms than those offered. It was recommended also that £10 be granted towards the support of these orphans.

The Secretary had reported that six annuitants had died during the year, leaving thirty-six on the list.

The Committee recommended that six annuitants be elected in December next, and had drawn up a list of ten approved candidates.

The Committee also recommended the sale of some gas shares standing in the name of the trustees, and the re-investment of the money in 5 per cent. debentures.

The report and recommendations were carried unanimously.

GENERAL PURPOSES.

The report of this Committee, which as usual was read in committee, included the usual letter from the Solicitor, stating the progress which had been made with cases placed in his hands. From this it appeared that Charles Campbell, 555, Rochdale Road, Manchester, had paid a penalty of £5 and costs, and J. C. Copley, 51, Robin Hood Street, Nottingham, under stress of a county court order for committal in default, had also paid £8 8*s.* 3*d.* as penalty and costs.

Several cases of alleged infringement of the Pharmacy Act had been considered, and proceedings were recommended to be taken.

The Council having resumed, the report and recommendations were unanimously adopted.

PHARMACEUTICAL EXHIBITION.

Mr. SYMES moved the following resolution of which he has given notice:—

"That an Exhibition of Pharmaceutical and Chemical

Apparatus and other objects of special interest to pharmacists be held in the Society's Rooms in May next, and that the Library, Museum and Laboratory Committee be requested to consider and report on the best means of carrying it out efficiently."

He need not say much in support of this motion, inasmuch as two exhibitions had already been held, and on the last occasion on which he brought the subject before the Council with a view of ascertaining whether it was the opinion of the majority that such an exhibition should be held every year, an amendment was passed to the effect that exhibitions should not be held more frequently than once in three years. Of course that did not bind the Council to hold one every three years, but seeing that two years had elapsed and the third would arrive in May next, he thought most gentlemen would agree with him that if such an exhibition was to be held in the Society's rooms it should be made successful, and to render it successful it was necessary that there should be longer notice of the intention than had hitherto been given. The last exhibition held there was an international one. Though he did not wish to deprive the Vienna people of the credit of having instituted the first International Exhibition he must say that the views in this country concerning an exhibition were so cosmopolitan that there was no idea of anything but an international exhibition; and there had been on the previous occasion exhibits from France, Germany, America and elsewhere. To get exhibits of the desired character, and to allow persons sufficient time to consider and prepare their exhibits, some months' notice should be given, in order that there might be ample time to communicate with persons abroad. As yet there had been no exhibits from Austria, although, as had been seen recently, Austrians were capable of producing things which were not familiar in England. The recent exhibition at Vienna might be adduced as a reason for not holding one there, but he thought, on the contrary, that some of the articles there shown might very likely be sent over here. He looked on this as an educational question—not as educating students but as helping men engaged in pharmacy to discuss the merits of various appliances and products which were shown. The day was gone by when preparations were made by secret apparatus, but the day would never pass when a large amount of skill would hold its own. What was wanted was that those men that possessed skill should have greater experience in the means by which that skill could be made available. He hoped the motion would be carried, as he believed it would be very acceptable to the trade.

Mr. Radley, in seconding the motion, said he thought the country members generally were very much interested in such exhibitions, and that the time named was one when there would be a large assemblage of country members in London.

Mr. Schacht in the abstract approved of the proposal because it tended to the cultivation of the art of pharmacy, and in a certain degree to open all eyes to what was going on. Now he should like very much, inasmuch as the matter would probably be referred to a Committee of the Council, chiefly composed of London members, to know whether the members of that Committee felt that it would be in their power so to manage this affair that it should be of sufficient interest generally, and on the other hand not exposed to the abuse of advertisement. Of course neither Mr. Symes nor Mr. Radley wished to encourage that, but they must know that that was a direction in which the exhibition might be abused. He could not remember with perfect gratification the last exhibition, because his impression was that a large portion of it consisted of articles which the Society ought not to be called upon to advertise. He, therefore, wished to gather the opinion of the Committee whether that class of exhibits could be eliminated, and if not he thought it would be wise not to hold an exhibition.

Mr. Hampson said he took it for granted that the members of the Committee would be anxious to answer the question, but on the other hand he thought the Council might trust half a dozen intelligent gentlemen to so conduct the affairs of this exhibition, that it would not be open to the reproach just referred to. He quite sympathized with Mr. Schacht's view, but at the same time the danger was not confined to pharmaceutical exhibitions. The remarks of Mr. Schacht would strengthen the hands of the Committee and give the key note to its action, and he was quite sure, from past experience, it would be able to carry out the work with satisfaction. Another point was, had the time arrived when an exhibition could be held with advantage to the Society, and was it likely that it would be supported by a sufficient number of novelties?

Mr. Butt said he was a member of the Committee conducting the last exhibition. Several hundred circulars were sent out, and the replies were very few, and up to within a few days of the opening there was every appearance that the scheme would prove abortive. It was only by extending the limits and admitting objectionable things which had a certain interest to some people that the Committee succeeded in getting a sufficient number of articles to make an exhibition. There were a large number of things which he individually, and he believed the other members of the Committee, objected to, and which would not have been admitted if there had been a sufficient number of applications to make anything approaching an exhibition without them. As far as his experience went a second attempt would be equally abortive if the managers took the trouble to exclude everything in the nature of an advertisement. Several things were then excluded, and the Committee was hauled over the coals for having done so. For himself he must say that if it were decided to hold another exhibition he must decline to act on the Committee, first because he was not satisfied with the result of the Committee's labours last time, and, secondly, because he had not sufficient leisure.

Mr. Williams said it was a very troublesome and expensive thing to get up specimens worthy of such an occasion, and when an exhibition was only opened for one or two days it became a serious question with manufacturers, and they would only go to this expense and trouble when they saw that it would pay them to do so. He did not object to the principle of the thing; on the contrary he thought the first exhibition was a very great success, but the second was not so good, because there a certain set of people came forward who discovered that this was a good means of pushing certain articles. If it were decided to hold another exhibition he should be sorry to oppose it, but if a committee were appointed it ought to be perfectly impartial, and it would have a very disagreeable task before it; such a committee ought to be thoroughly and loyally supported by the Council in its decisions.

Mr. Robbins, as one of the Committee of the last exhibition, agreed with Mr. Williams that it had a very disagreeable and difficult task to perform. On the last occasion the Committee went into the matter most zealously, and everything possible was done to make the holding of an exhibition known beforehand; but when it came to almost the last moment it was found that there was very little sent in that was worthy of being exhibited, and consequently the Committee was driven to take what was sent or to have no exhibition at all. An attempt was made to discriminate, and some things were excluded, and then umbrage was taken outside at the decision. If the same thing were repeated he certainly thought the Council should be very careful not to encourage any such discontent by giving ear to it. He was sure that any committee appointed would act conscientiously, and after doing so it would not like to be charged with acting unfairly. He did not think there was any probability of there being a sufficient number of persons interested in pharmacy present in May next to make it worth while to try the experiment.

Mr. RICHARDSON said he had hitherto been a strong advocate of exhibitions of pharmaceutical apparatus and other interesting articles at the annual meetings, but after the discussion that morning, he thought very few would have the temerity or enterprise to send many articles to such an exhibition. It was impossible to hold a successful exhibition within those walls, if it were to be one worthy of the pharmacy of Great Britain. To that end contributions ought to be solicited from all the other countries, France, Germany, Austria, and America; but there was not room in that building for such a collection, and if there were room the advantages offered were not, as Mr. Williams suggested, commensurate with the trouble and expense which exhibitors would be put to. He was anxious to give country members every inducement to come up to London to an annual meeting, but if they were brought up to London ostensibly to see an exhibition worthy of the rising generation of pharmacists and then presented with one which had been taken from town to town, as was sometimes the case, the result would not be satisfactory. There were persons who would have the enterprise to fill the rooms with articles which might be of interest to some people; but the question was whether it would be wise for the Society as an educational body to encourage that sort of thing. If an exhibition were held, let it be one of practical pharmacy, of interesting apparatus, such as Mr. Schacht suggested some years ago, a kind of museum, but after what had been said he should ask Mr. Symes to consider whether it would be advantageous to hold one next year. He begged to say he should vote for the motion if it was put.

Mr. GREENISH said he should oppose the proposition for the holding of an exhibition of pharmaceutical apparatus and so forth in the Society's rooms. His experience was that there were not sufficient novelties to render it interesting, unless those things were introduced which were the negation of true pharmacy. He should say, have the exhibition elsewhere, and let those who exhibited advertise as much as they liked. If medical men took the advertisement portion of the Journal as their pharmacopœia, which some of them seemed to do, it might be useful to them to see such specialities exhibited; but if the exhibition was to be confined to pharmaceutical preparations and apparatus he was sure there was not sufficient of novelty to make it interesting. Contributions of apparatus from abroad had been referred to, but it would be very wrong to invite gentlemen on the Continent to send articles to an exhibition lasting only a couple of days without clearly explaining all the circumstances. On the last occasion great fault was found with the Committee because it rejected certain things not in accordance with the printed rules, and he hoped if the experiment were again tried some clear instructions would be laid down for the guidance of the Committee, and that its decisions would be supported by the Council.

Mr. WOOLLEY should not like it to go out to the world that Mr. Greenish was of opinion that there was nothing new under the pharmaceutical sun.

Mr. GREENISH remarked that what he said was that there was not sufficient novelty to make an exhibition interesting, unless objectionable things were allowed.

Mr. WOOLLEY said one great advantage of this motion was that it came before the Council in good time, so that the Committee would be able to form an opinion whether there would be a sufficient number of articles of interest forthcoming. That the Committee would ever get an exhibition of that highly respectable superæsthetical nature, free from advertisement, which some people seemed to wish for, he very much doubted. He and other gentlemen present had exhibited, and he should like to ask them whether they exhibited on purely moral principles and whether they had not some idea of advertisement in the matter. He would strongly support the proposition.

Mr. GREENISH said every year since he had attended the annual meeting of the North and South German Association there had been an exhibition in connection with the meeting; but it had been found as he had stated that there were not sufficient novelties, and on the last occasion an application was signed and presented to the Association asking that the exhibition should not be held every year, but, at the discretion of the President, every three or four years.

The PRESIDENT said it was perfectly well known in London that there was only one way of getting up an exhibition. It was not worth the while of anyone to exhibit in any exhibition unless he received some *quid pro quo*; either you must pay the maker to exhibit, or you must give him an opportunity of advertising his wares. The question was, which of these two courses was the better one to adopt. If it was desired to have a high class exhibition, a thing really novel and interesting, people must be paid to bring their things; if they wanted an exhibition of ordinary commonplace things, the proprietors of those things which they had already advertised, and were advertising, would no doubt be glad to come and advertise themselves again. Personally he did not object to either one or the other very seriously, but it was a little difficult, constituted as that Society was, to impose on a small committee the very awkward task of rejecting exhibits of some of their fellow members on the ground that they were not suitable. What took place last time must take place again. The Committee must apply to pushing men engaged in pharmacy to come, and must give them what they call "facilities." He would ask Mr. Symes if he had considered the very small number of people who came to such an exhibition. Had he compared it with what was called the Sanitary Exhibition, lately held at Knightsbridge, which some people who obtained medals there might think was a success, but in point of the numbers who visited it, and financially, was a complete failure. It was quite in harmony with the position of the Society to encourage country members to come to London at the Annual Meeting, and the Council endeavoured to do that by the liberal way in which it dealt with the Conversazione; but when the relatively small number which constituted the meeting was considered, it was not worth the while, commercially, of any firm to exhibit, unless it either had its expenses paid or something in the shape of an advertisement, which was looked upon as a *quid pro quo*.

The VICE-PRESIDENT said the remarks of the President, though very useful, had left him very much where he was, and his position was one of great hesitation in the matter. Reference had been made to the country friends and provincial members, and there was great force in the remark that two days was a very short time for an exhibition, to which he would add that one of those days was practically absorbed in the Annual Meeting. The other class of people, experimental pharmacists of a high class, would not care to come to an exhibition unless it contained novelties; it would be no pleasure to them to see things they already knew, and few men would care to go to the expense of sending new apparatus or new products for two days.

Mr. HILLS suggested that the permanent Museum should represent an exhibition worthy of the Society, and that such a one as now proposed belonged rather to commercial enterprise.

Mr. YOUNG said he had not the pleasure of seeing the last exhibition, but he observed that the motion referred to an exhibition of apparatus; it seemed to him it would be a pity to run the risk of damaging the premises, which had recently been redecorated, by setting up soda-water and other apparatus. He agreed with Mr. Hills that the Museum should be constantly attended to, and everything of a new and interesting character should be sent there, but it would only lead to confusion to introduce cartloads of apparatus.

Mr. Bottle thought a very good suggestion might be gathered from the remarks of the President. The last exhibition did not impress him very much, and he agreed with Mr. Woolley that it was impossible to get an exhibition which did not include the advertisement element. He thought it was worth consideration whether the Conversazione should not be held within the Society's own walls, and made on the next occasion an exhibition, paying for the introduction of what were really novelties or objects of interest which would be valuable from an educational point of view to the members of the Society.

Mr. Symes said the idea originated in his mind partly from the recollection of the old Conversazione in that building, where improvements and novelties in pharmacy were exhibited, and attracted such large numbers that the building was not found large enough to accommodate them, and partly from the scheme which Mr. Schacht brought forward some time ago for having a permanent exhibition of modern apparatus. The Conversazione had been moved to South Kensington, and Mr. Schacht's proposal was negatived from want of accommodation, and consequently there was no opportunity for showing those improvements which were constantly taking place in pharmaceutical apparatus and the preparations made by them. All were aware that exhibitions were one of the modern means of imparting knowledge. A great deal had been said about the last exhibition, but nothing about the first, which he was perfectly satisfied was a thorough success. Nothing good could be obtained without having an evil, and the evil must be put up with for the sake of the good. The chief object of any person in sending apparatus or preparations was to make them known. If it were objectionable to countenance any kind of advertisement, why were advertisements inserted in the Journal? The first time he suggested such an exhibition he was told there would never be six persons in the room at one time, and at another that there were no such things as pharmaceutical apparatus existing; yet there had been apparatus exhibited, and it was known that the rooms were crowded during the greater part of three days. He quite agreed that persons should not be invited to send contributions from abroad without being fully aware of the limits of the exhibition. The argument that the Germans were not going to hold an exhibition next year seemed to him in favour of holding one there. It seemed, however, to be the opinion of the majority that such an exhibition was not desirable, and he, therefore, hesitated somewhat to press the motion; but he felt that it would be losing a great opportunity, and if the Council would go earnestly into the subject there was no fear of the result.

Mr. Schacht suggested that the scheme would be more likely to elicit general approval if the exhibition were limited to apparatus: educationally, it would answer the whole purpose, and it would be likely to eliminate that element which was considered by some open to objection. The Museum contained almost all the preparations likely to be seen, but very little in the shape of pharmaceutical apparatus.

Mr. Symes thought it would narrow the exhibition too much to confine it to apparatus, and he should prefer the motion being put in its original form. Of course the Committee would have the power of selection.

On being put to the vote the motion was lost by 10 votes to 8.

For—Hampson, Radley, Richardson, Savage, Schacht, Symes, Williams and Woolley.

Against—Atkins, Bottle, Borland, Butt, Gostling, Greenish, Hills, Robbins, Squire and Young.

The President and Mr. Churchill did not vote.

The Proposed Curriculum.

Mr. Schacht then moved the following resolution:—

"That a Committee be appointed to frame, with the assistance of the Solicitor, such modifications of the bye-laws as will give effect as far as possible to the resolutions in respect of the future training of candidates for examination under the Pharmacy Act which were adopted by the Council on March 7, 1883."

It appeared to him that this was the next proper step for the Council to take after having come to the resolution at which it arrived in March last; from that time to the present action had been a little bit trammelled by the possibility of an amended Act of Parliament being passed, but the hopes in that direction had been disappointed, and it was just as well, in view of another session being equally unfruitful in that respect, to see whether the powers the Society already possessed would not allow of making the modifications which had been generally approved. Looking as carefully as a layman's eyes could look at the legal documents, he found nothing in what was proposed antagonistic to a single line of the Charter as far as he understood it. It would be noticed that very early in the declaration of the Charter it said, "For the purpose of advancing chemistry and pharmacy and promoting an uniform system of education of those who should practise the same," and if the charter were followed carefully it would be found that in order to carry out those fundamental ideas certain powers were given to the Council which was to regulate all matters and have power absolutely to formulate and alter the bye-laws subject only to the approval of the Privy Council. In the Act of 1852 this was repeated in almost identically the same language. There was nothing whatever to limit the power of the Council to modify from time to time the bye-laws, which it itself had created, beyond the one provision that every such modification must receive the sanction of the Privy Council. With regard especially to the examinations, it said in one Act of Parliament, "And such other subjects as may from time to time be determined by any bye-law." He did not wish to say that the Council had or had not this or that power, but bringing ordinary common sense to bear upon the subject, he thought with the assistance of the legal adviser the Council would be able to accomplish what was desired under the existing Act of Parliament.

Mr. Symes seconded the motion. He said the Council had decided that it was desirable to carry out certain modifications of the bye-laws, and there was no reason why that record should remain on the books without some action being taken to carry it into effect. The first thing which occurred to his mind was that it might weaken their claim to get an Act of Parliament passed next session, but on the other hand there was no guarantee that an Act of Parliament would be obtained next session, nor was there any certainty that in that Act some of the things which the Council might consider desirable would not be eliminated, therefore, if the Council had power to carry out these resolutions irrespective of a new Act of Parliament—he was not a sufficient lawyer to know whether it had that power or not—it was desirable to do so. Of course any alterations in the bye-laws would have to go before a special meeting of the Society and the Privy Council, but if they had the support of a special meeting it might have a beneficial influence on the future Pharmacy Act, as it might reduce the number of points for which it was necessary to go to Parliament.

Mr. Borland said he had frequently expressed his opinion as to the illegality of the position which some members of the Council took up, and after again looking at the two Acts he still adhered to the same view. The proposition to enforce a curriculum was the point which seemed to him altogether illegal. The Acts of 1852 and 1868 distinctly stated that the examiners were to examine all persons who presented themselves, irrespective of any curriculum or mode or extent of education.

The President remarked that if the discussion were going to take the line which Mr. Borland seemed to indicate, he must ask him to read the whole of the paragraphs he had referred to. It was provided that the examinations should be conducted under such regulations as the Council should lay down

Mr. Borland said that referred to the mode of conducting the examinations. It gave the Council no power in his opinion to impose a curriculum. He was quite agreed that better education should be demanded of the candidates, but in face of these two Acts of Parliament, and the very explicit language to be found there and in the Charter, he did not see how a curriculum could be imposed. It was especially provided that the bye-laws should not be repugnant "to these presents, or to the laws of this our realm." The laws of 1852 and 1868 distinctly stated that any person might present himself to the Board of Examiners. The Council had no power to limit the numbers of candidates by a curriculum. It would be wise, therefore, first to obtain a legal opinion before appointing a Committee to frame new bye-laws, and he would move as an amendment, that the Solicitor of the Society be consulted as to the legal applicability of the resolution respecting the future training of candidates of pharmacy, which was adopted by the Council on the 7th of March.

Mr. Williams thought such an amendment was almost involved in the motion, since it proposed that the Committee should act with the Solicitor, who would not allow them to go far wrong. He was glad to find that Mr. Schacht had seen the wisdom of consulting the Solicitor. He thought with Mr. Borland that the Acts of Parliament did not give power to carry out the resolution which the Council agreed to on a former occasion. Originally he objected to the principle of an enforced curriculum, not that he wished to limit the amount of education required for pharmacists, but because he thought the expense of such a course was more than could be fairly called for from a man who, in after life, was only destined to receive in so many cases so small a remuneration. He had, however, since then seen a great many pharmacists all over the country, and found that his idea was not borne out by what they thought of the matter. The general opinion undoubtedly was that a curriculum was a good thing, and that it would not be to the disadvantage of pharmacists generally that education should be pushed forward. He heard this opinion freely expressed lately at Southport, and last year at Southampton, from which it appeared that the trade was not quite so bad as some people would like to make out, because it seemed the opinion of the leading men in pharmacy that it was not only not a bad thing, but a good thing to increase the cost of pharmaceutical education in this way. He was glad to find that this was the view of the majority of the trade, and hoped experience would not prove that they were wrong. On this ground he should have the greatest pleasure in supporting Mr. Schacht's motion, now that it was combined with a reference to the legal adviser, because that seemed to him quite necessary. He should be very sorry for a committee to draw up bye-laws which, when they came to be enforced were found to be illegal.

Mr. Borland said he would withdraw his amendment, as he found Mr. Hampson was about to move one which would cover the same ground, and which he would be happy to second.

Mr. Hampson then moved as an amendment—

"That increased statutory powers be obtained before giving effect to the resolutions in respect of the future training of candidates for pharmacy adopted by the Council on March 7, 1883."

He did not wish to re-open a discussion on the question itself, but accepted the vote of the Council, but still he thought he might ask the question, Why this unnecessary haste? what was the object of pressing on this matter, in his view, so unwisely? The two Government assessors did not agree with the proposals—one of them at any rate distinctly did not—and if the proposed new bye-laws were submitted to the Privy Council, the opinion of those gentlemen would no doubt be taken as to the desirability of sanctioning them. He remembered, years ago, when he first entered the Council, several bye-laws were proposed, which ultimately received the sanction of the Society, which he opposed, because he did not like to interfere unduly with the educational arrangements of any person who wished to enter the trade. At that time he remembered very distinctly the Solicitor stating that the Society had not the power to make bye-laws or regulations of this kind; yet Mr. Schacht wished a committee to be appointed to propose the most radical changes in the mode of education, and to call in the Solicitor to help frame these regulations; he did not say to ask his opinion whether they were legal. The Solicitor would frame the bye-laws, no doubt, and they would be presented, and if Mr. Schacht manifested his usual eloquence and persuasive power, no doubt they would be accepted. For his part, he did not want to break the law, and he believed the Act of Parliament was already strained to the utmost. Was it wise when the Council was going to Parliament for a new Pharmacy Bill to give the Government the impression that it was not worthy of trust? He believed this would be the result if the Council endeavoured to override the Act of Parliament. How was it that Mr. Schacht and others when labouring in the Parliamentary Committee on the new Pharmacy Bill thought it necessary to include full provisions for carrying out the important educational change they so much desired if they already had power under the present Act? He certainly thought a curriculum was desirable, but who had asked for the organic change? The Government assessors had not asked for anything of the kind, they did not say the examinations were insufficient—they said just the contrary; the public had not demanded it, the Privy Council had not demanded it, nor had the candidates; there was no necessity to urge the matter unduly forward, and he was quite sure that by doing so the Council would weaken its influence when it went to Parliament for a new Bill.

Mr. Williams did not see how the Solicitor could be consulted until he knew what he was to be consulted about.

Mr. Greenish said he recollected on one occasion the Solicitor stating most distinctly that the Society could not make these changes under the present Act of Parliament. He believed he had attended every Committee meeting since, and he had no recollection of the Solicitor having expressed any different view.

The President said the solicitor said they could not be carried out without certain provisoes.

Mr. Greenish said the remark of the Solicitor was, "If you wish it, gentlemen, here I am to obey your instructions." But nothing could be more emphatic than his opinion that under the present Act of Parliament the Society could not make these changes.

The Vice-President said the motion was exceedingly simple, and it was quite obvious the Society could only do that which was legal, and he hoped they only wished to do so. They would know what was legal by consulting their legal adviser. He should not think of taking the responsibility of saying what was legal, but should, as he always did, throw the responsibility on a man who understood the subject. An amended Act of Parliament might be very remote, and this matter being so important why should it be referred to the ides of March, seeing it had received the sanction of the Council almost unanimously, and, as Mr. Williams had said, had received the approval of the whole country?

Mr. Williams said he should hold the Solicitor responsible. His duty would not be to act as the clerk of the Committee, but to advise it how far it could go.

Mr. Young said when this subject was discussed in March he voted for the resolution; but on the point of legality or illegality he did not feel able to give an opinion, and hoped the Council would be advised whether the proposed change was legal or not. If the motion were slightly altered it appeared to him it would be unobjectionable, and the Council certainly should not consent to anything as to the legality of which there was any doubt. The first thing would be to consult with the Solicitor; not to go to him and say we have appointed a Committee to meet you and frame these bye-laws, but to take his advice and report. Mr. Schacht seemed to assume that there was power to do this, whilst other gentlemen had considerable doubts on that point.

Mr. Bottle said that some few years ago the question might fairly have been raised whether there was power to make such modifications in the bye-laws as to give effect to the resolution of March last, but all doubt had been removed from his mind by the fact that the Society had already made bye-laws on similar lines affecting the examinations; for instance, it had provided that no person should be admitted to the Major or Minor examination who had not attained the full age of twenty-one years. It might be said that it had no right under the Act of Parliament to define that a man should be twenty-one years old, and again, "unless he shall satisfy the examiner that for three years he had been registered or employed as an apprentice or student." Therefore, having travelled in that direction, and having obtained the concurrence of the Privy Council to such a wide interpretation of the Act of Parliament, he took it the Council was quite at liberty to go further and impose a curriculum. He was, therefore, quite prepared to support Mr. Schacht's motion, and would even go further and suggest that there were other alterations in the bye-laws which might be made at the same time.

Mr. Schacht, in reply, said Mr. Borland seemed to rely on the provision in the Act of 1852, that the Board of Examiners was compelled to examine every candidate who presented himself without any sort of limitation; but it did not run so in the Act itself. In the 8th section, it said that the Examiners "shall respectively have full power and authority and are hereby authorized and empowered to examine all persons who shall present themselves for examination under the provisions of this Act." That gave full power to the Council to make its bye-laws which should constitute the provisions of the examination. Therefore, it had ample power to do what it pleased. Referring again to the Charter, it said; "And we do further will and declare, that it shall be lawful for the said Council, to the best of their judgment and discretion, to make and establish such bye-laws as they shall deem proper and necessary for regulating the affairs of the said Society; and also the number and decriptions of its officers; and also the times, place and manner of examining candidates for admission." The time, place and manner, were all made matters of bye-law, and that brought the proposed modification thoroughly within the scope of its powers. There was, therefore, full power to provide that a candidate should not come up until he was twenty-one, and that he should not come until he had spent three years in a pharmacy, and in his opinion the same clause gave power to say he should not come up until he had passed a curriculum.

Mr. Greenish remarked that in the opinion of the Solicitor some of the bye-laws really over-rode the Act.

The amendment being put was lost by 13 votes to 4, viz.:—

For—Borland, Churchill, Greenish, Hampson.

Against—Atkins, Bottle, Butt, Carteighe, Gostling, Hills, Radley, Robbins, Savage, Schacht, Squire, Symes, Woolley.

Mr. Williams did not vote.

The motion was then put and carried.

The following gentlemen were appointed the Committee:—The President and Vice-President, with Messrs. Bottle, Butt, Hills, Schacht, Symes, Woolley and Young.

Mr. Hampson was nominated but declined to serve.

Assistant Lecturer on Chemistry.

It was unanimously resolved that Mr. Dunstan be appointed Assistant Lecturer on Chemistry and Physics for the ensuing year at a salary of £50.

The late Mr. Atherton.

The President reminded the Council that Mr. Atherton died at Tunbridge Wells on September 13 last. Mr. Atherton had not only been a member of the Council, but Local Secretary of the British Pharmaceutical Conference at its meeting at Nottingham, probably one of the most successful meetings the Conference had ever had, and his sympathy and activity on that occasion earned for him the gratitude of every pharmacist present. It was only becoming, therefore, that the Council should record its sense of the loss which the Society had sustained by the death of Mr. Atherton, and with the sanction of his colleagues he would write a letter of sympathy to the widow.

A resolution to this effect was carried unanimously.

A letter was read from the Secretary of the Chemists and Druggists' Trade Association, soliciting that an opportunity should be afforded to the Committee of that body of conferring with the Council of the Society on the subject of the proposed Pharmacy Acts Amendment Bill. The President and Secretary were instructed to arrange a convenient time for such a meeting.

EVENING MEETING.

Wednesday, October 3, 1883.

The first Evening Meeting of the Session 1883-4 was held on Wednesday, October 3, at half-past eight o'clock. The chair was taken by the President, Mr. Michael Carteighe, and the room was crowded to its utmost capacity.

After a few words from the President as to the business of the evening, he called for the—

Report on the Chemistry and Pharmacy Class.

Professor Redwood said that with regard to the past session he was fully justified in saying that good work had been done, and that there had been no falling off, but rather an improvement in the condition of the School. Speaking specially of his own class he could say conscientiously that he had never had a more orderly and attentive set of students than those of the last session. That they had been industrious and fairly successful in their studies would appear from the list of prizes and certificates; but before reading the names of the successful competitors, he must say a word as to the future. This was an age of rapid progress; the old slow system of travelling had been superseded by one of a more expeditious character, and the change thus effected seemed to have influenced other operations besides those of locomotion. Nowadays they had to go over the ground more rapidly than formerly, and thus the course of instruction which used to occupy ten months was now compressed into five. This, of course, made the work much harder, but owing to the principle of division of labour, it was capable of accomplishment, and even of doing more work than was formerly done; practical dispensing being now included in the programme. A class for teaching this subject had been organized under the management of Mr. Dimmock, and during the ensuing session he was glad to say that Mr. Joseph Ince would be associated with him. Again, with reference to his own lectures on physics and chemistry, he had hitherto had the assistance of Mr. Dunstan, and it was proposed that for the future Mr. Dunstan should take a more prominent part in the teaching. That day Mr. Dunstan had been appointed by the Council Assistant Lecturer on Physics and Chemistry, and would co-operate with him in the lectures and demonstrations, not only at the lecture table in that hall, but also in supplementary lectures which it was proposed to give in the afternoons. It would be seen, therefore, that they were endeavouring to make arrangements for increasing and extending the teaching power of the institution. Professor Redwood concluded by reading the names of the successful students.

The following is a list of the awards of medals and certificates to students in this class:—

FIVE MONTHS' COURSES.

FIRST COURSE.

Bronze Medal	David Rees.
Certificates of Merit	Edward Baily. Charles Ranken. Sidney Phillips. Francis Ransom. Thos. Southall Dymond. William Edward Crow. James Haddock. David Low. Edward Ernest Sewell. Arthur Pumphrey.

SECOND COURSE.

Bronze Medal	Lewis Walter Hawkins.
Certificates of Merit	John Chinery Wiggin. Ernest James Reynolds. John Rodman Mowatt.

SESSION. TEN MONTHS.

Silver Medal	David Rees.
Certificates of Honour	Francis Ransom. Edward Baily. David Low.
Certificates of Merit	Charles Ranken. William Edward Crow. Thos. Southall Dymond.

The following are the questions that were set for these examinations:—

FIRST COURSE.

BRONZE MEDAL AND CERTIFICATES.

Hours—Ten till Two.

1. What physical force does the weight of a body represent?
2. What are the points in the construction of a balance for estimating weight upon which the accuracy of the estimation chiefly depends?
3. What is the meaning of the term "*mechanical equivalent of heat*," and what is the mechanical equivalent of heat as expressed in "*foot pounds*," according to either the Fahrenheit or Centigrade scale?
4. What is the latent heat of the vapour of water respectively at 112°, 212°, and 312° Fahr.?
5. Briefly explain the undulatory theory of light.
6. In a galvanic battery composed of zinc and copper plates excited by an acid, which is the positive and which the negative terminal plate within and also without the acid?
7. Name the non-metallic chemical elements.
8. Describe the Pharmacopœia process for the preparation of "*Acidum phosphoricum dilutum*," giving full details of the mode of operating, the objects contemplated, and the means by which they are accomplished.
9. Name the oxygen acids of phosphorus, and show how they are produced from the oxides.
10. Describe the production of calomel and corrosive sublimate, and briefly explain processes which were formerly and those which are now adopted for the preparation of calomel.
11. Name some of the principal hydrocarbons of the fatty group, giving their typical formulæ.
12. Give the composition of cyanogen, and describe its mode of production and its characters and tests.

SECOND COURSE.

BRONZE MEDAL AND CERTIFICATES.

Hours—10 *till* 2.

1. What are the values respectively of the gram and kilogram, expressed in grains? What are the relations existing between the gram, decagram and centigram?
2. Describe and explain the method of taking the specific gravity of paraffin.
3. What is the weight of a fluid ounce of sulphuric acid, B.P.?
4. Describe the construction and explain the principle of action of the siphon.
5. Explain what is meant by the transmission of heat. Name a solid that possesses the property of transmitting heat in a high degree, and another that possesses the property in a low degree.
6. What is the composition and the assumed constitution of borax? What are its sources, and how is the borax of commerce usually prepared? Describe some of the properties of borax.
7. Describe the process by which zinc is obtained from its ores, the properties of the metal, and the different methods by which the oxide may be prepared.
8. Describe the transformations which may be effected between the members of the ligneous, saccharine, and amylaceous group of bodies, and the properties of the products.

SESSION.

SILVER MEDAL PRIZE AND CERTIFICATES.

Time allowed, three hours.

1. Define the meaning of the terms "inertia" and "force" as used by physicists.
2. State in general terms the methods adopted for determining the specific heats of bodies, and explain the relation of the specific heats of bodies to their atomic or molecular weight.
3. Explain the principles upon which the process of spectrum analysis is founded, and the general nature of the results obtained by this process.
4. What is meant by the statement that certain substances, mostly liquids, deviate or turn the plane of vibration of a ray of polarized light from its normal direction? Describe a simple arrangement and construction of apparatus for showing this result, and explain the action of each part of such apparatus.

Time allowed, three hours.

5. Describe the ammonia process for the production of carbonate of soda. State what the impediments were to its general adoption when first introduced, and what circumstances have since tended to favour its success.
6. Describe the production of lead from its ore; the method of eliminating silver from lead by Pattinson's process, and also by cupellation; the properties of the metal and also of its oxides, pointing out the distinction between litharge and massicot.
7. Explain the circumstances under which water may become contaminated with lead by remaining in contact with the metal, and the conditions under which such contamination may be prevented.
8. Describe the process for the artificial production of urea. State the compositions respectively of urea, cyanuric acid, and cyanic acid, and explain the manner in which these may be produced one from another by successive transformations.

REPORT ON THE BOTANY AND MATERIA MEDICA CLASS.

Professor BENTLEY was next called upon to report upon the Materia Medica and Botany Class. He said it was unnecessary for him to do otherwise than do so very briefly, because he could only repeat that which he had said on so many occasions previously. All he would say was that in diligence, intelligence, behaviour, and everything which was the model of a student his students of last year were types. He was also glad to say that in point of numbers the class was the best he had had for many years. He would not go into the honours question further than to say that those gentlemen whose names appeared on the list of prizes awarded by the Council on his recommendation were thoroughly entitled to the distinctions awarded to them. No certificate of merit, honour, or medal, or any kind of award was given in that institution without a high standard of excellence being attained. Having read the list of names he concluded by saying he was extremely gratified with his class of last year, which was of a high average merit, and he was quite sure that those who had received distinctions would take an honourable place in the ranks of pharmacy of the future.

The following is a list of the awards of medals and certificates to Students in this class:—

FIVE MONTHS' COURSES.

FIRST COURSE.

Bronze Medal	William Edward Crow.
Certificates of Merit	Edward Baily. David Low. William Lloyd Williams. Sidney Phillips.

SECOND COURSE.

Bronze Medal	John Chinery Wiggin.
Certificate of Merit	Ernest James Reynolds.

SESSION. TEN MONTHS.

Silver Medal	Edward Baily.
Certificates of Honour	Francis Ransom. William Edward Crow. William Lloyd Williams. Equal { Charles Ranken. Equal { David Low. Edward Ernest Sewell.
Certificates of Merit	Thos. Southall Dymond. Arthur Pumphrey. John Chinery Wiggin.

The following are the questions that were set at these examinations:—

FIRST COURSE.

BRONZE MEDAL AND CERTIFICATES OF MERIT.

Hours from 10.30 *till* 2.

1. What is Chlorophyll, where is it found, and what is its action in the plant?
2. Describe the internal structure of an Acotyledonous stem.
3. Distinguish between Epiphytes, Parasites and Saprophytes. What are the distinctive characters of roots and stems?
4. Define the following:—Thalamus, Receptacle, Loculicidal, Septicidal, Gymnospermous, Germinal Vesicle, Foramen, Arillus, Caruncule and Albumen.
5. Describe the botanical and geographical sources of Ammoniacum. What are its general and chemical characters, and enumerate its official preparations?
6. Enumerate the official plants of the order Rutaceæ. What are the botanical and geographical sources of Buchu leaves? Describe their botanical, general, and chemical characters.
7. How is Balsam of Tolu obtained. What are its botanical and geographical sources, its general and chemical characters, and its official preparations? Explain what you mean by a Balsam.

SECOND COURSE.

BRONZE MEDAL AND CERTIFICATES OF MERIT.

Hours from 10 *till* 1.30.

1. Describe sclerenchymatous cells, hyphal tissue, and sieve tubes.
2. Describe the structure of epidermal tissue.
3. Define the following terms:—(*a*) pinnate pinnatifid, conduplicate, as applied to leaves; (*b*) panicle, umbel, cyme, as applied to the inflorescence; (*c*) and exserted, didynamous, gynandrous, and syngenesious, as applied to the stamens.
4. Describe the structure of the embryo, and explain the process of germination.
5. What are the botanical sources of bitter and sweet almonds? Describe their general and chemical characters. Enumerate the official plants of the Rosaceæ.
6. What are the botanical and geographical sources of Liquid Storax? How is it obtained, and what are its general and chemical characters? What is a Balsam?
7. What official drugs are derived from the Gentianaceæ? Enumerate their official preparations. Describe the physical and chemical characters of Gentian Root.

SESSION.

SILVER MEDAL AND CERTIFICATES.

Hours from 10 *till* 1.

BOTANY.

1. What are aleurone grains, crystalloids, and globoids, and where are they commonly to be found?
2. Describe the internal structure of aerial and submerged leaves.
3. Define the terms acropetal, centripetal, and centrifugal, as applied to the inflorescence, and describe the following kinds of inflorescence: — Raceme, corymb, spadix, capitulum, scorpioid cyme, and verticillaster.
4. Describe the following kinds of fruits:—Legume, achenium, etærio, drupe, capsule, pyxis, cremocarp, and siliqua. What is a pseudocarp?
5. Distinguish between the Rosaceæ and Ranunculaceæ, Compositæ and Dipsacaceæ, Labiatæ and Scrophulariaceæ, Iridaceæ and Amaryllidaceæ.
6. Give the essential characters of the following natural orders, and enumerate their official plants:—Papaveraceæ, Rutaceæ, Umbelliferæ, Oleaceæ, Polygonaceæ, and Liliaceæ.

SILVER MEDAL AND CERTIFICATES.

Hours from 2 *till* 5.

MATERIA MEDICA.

1. Describe the method of obtaining Opium. State the characters of good Opium, and enumerate its official preparations.
2. What are the botanical and geographical sources of Peruvian and Savanilla Rhatany? Show how they may be distinguished from each other; and mention the active constituents, medicinal properties, and official preparations of Rhatany.
3. What are the botanical sources of annulated, striated, and undulated Ipecacuanhas? Describe their general characters, and enumerate the official preparations in which Ipecacuanha is contained.
4. What are the botanical and geographical sources of the official Santonica, and describe its general and chemical characters? Enumerate the official plants of the Compositæ.
5. What are the botanical sources of the official Jalap and Tampico Jalap, and how would you distinguish the official Jalap resin from the resins of Tampico Jalap, Scammony, and Guaiacum?
6. Enumerate the official plants of the Euphorbiaceæ, and mention the parts or products of each which are directed to be employed in the British Pharmacopœia. Describe the general and chemical characters of Cascarilla Bark, and state its official preparations.

Report on the Practical Chemistry Class.

Professor Attfield said he had already presented two reports to the Council, one on the School, and one on the results of the examination; he would merely state as briefly as possible the leading points of those reports. First as regards the numbers they had had a better session than for several years past, and secondly the average period for which the pupils had studied had been longer than for twenty years past. No less than twenty-eight of the pupils studied for the whole session of ten months. The number was no doubt small, but it must be satisfactory to all who were interested in carrying on the work of pharmacy that the number of men who had taken advantage of the instruction offered by the Society was now increasing every year, and that the period of study was also increasing. As to the whole class, he had to report as usual, that the attendance was good, the diligence unexceptionable, and the progress satisfactory, while the conduct of the students had been without a flaw in any one case. One feature of the session had been that the students had increased their period of study, another was that they had never held a better all-round average of ability. On the one hand they had no third-class men, but he was bound to say on the other hand they had not had men of exceptional brilliance; which perhaps might explain how it was that no pupil of the School had succeeded this year in taking the Pereira Medal. After reading the names he said he regretted that Mr. Crow was not present to receive the silver medal, but his absence was very satisfactorily accounted for by the fact that he had been selected by the Secretary of State for the Foreign Department to occupy an honourable position in pharmacy in Hong Kong and had already left England.

The following is a list of the awards of medals and certificates to students in this class:—

Session. Ten Months.

Silver Medal	William Edward Crow.
Bronze Medals	Thos. Southall Dymond. David Rees.
Certificates of Honour	Charles Ranken. John Chinery Wiggin. William Lloyd Williams. Bernard Keene.
Certificates of Merit	Edward Baily. Francis Ransom. David Low. Edward Marsh. James Burden Barnes.

The following are the questions that were set in this examination:

July 13th and 14th, 1883.

(*Books and Memoranda permitted.*)

Standard number of Marks, 100.

FIRST DAY.

Hours 10 *to* 5.

1. Make a qualitative analysis of the accompanying "Mineral Water," and give the names of the salts you detect.

2. Report on the sample of "Syrup."

SECOND DAY.

Hours 10 *to* 3.

3. Is there any tin in the "Soup" supplied to you?

4. What substances are present in the "Teething Powder?"

Note.—*Manipulation as well as results will be scrutinized.*

The President then distributed the prizes to the successful students.

The Herbarium Prize.

Professor Bentley next made his report as to the Herbarium Competition, in which a medal and certificate were awarded as follows:—

Bronze Medal	Thomas Stephenson.
Certificate of Merit	Frederick Miller.

The Council Examination Prizes.

The President then explained the nature of the Council Prizes, and Pereira Medal, and called upon Mr. Sidney Plowman to report with regard to them.

Mr. Plowman said thirteen candidates had presented themselves for examination, but he regretted to say that after a long and anxious consultation with his colleague Mr. Southall they had been unable to recommend that the Pereira Medal should be given. But two gentlemen had achieved sufficient distinction to entitle them to the Council Prizes; their names were W. L. Williams, to whom the Silver Medal was awarded, and Edward Baily, who was to receive the Bronze Medal. He desired to say that those two gentlemen displayed great merit, but not quite such as would entitle them to the Pereira medal, which was the highest prize of the pharmaceutical year.

These prizes were therefore awarded as follows:—

Pharmaceutical Society's Medal (*Silver*); *and Books value £3, presented by Mr. T. H. Hills.*

William Lloyd Williams.

Pharmaceutical Society's Medal (*Bronze*); *and Books value £2, presented by Mr. T. H. Hills.*

Edward Baily.

The following are the questions that were set for this examination:—

BOTANY AND MATERIA MEDICA.

Time: 10 *a.m. to* 1 *p.m.*

In framing Answers, Candidates should not enlarge upon the Questions, but should confine themselves to giving, as briefly and clearly as they can, the information required.

BOTANY.

1. Give instances of irritability in the organs of plants, and describe any of the motile mechanisms connected therewith.

2. What is meant by suppression, augmentation or deduplication of the parts of a flower? Give instances.

3. What is callus? Explain its formation.

4. Describe the inflorescence and flowers of the Scotch Fir, and explain how fertilization is effected. Mention the peculiarity of the embryo.

5. Give the morphology of the sporangia of ferns.

MATERIA MEDICA.

1. What is the Botanical origin of Scammony, and how is it collected? What are the adulterations, and how may they be detected? How may it be distinguished from resin of Scammony?

2. What is the Botanical source of Duboisin, and what is its physiological effect?

3. In what part of "India" is Cinchona Bark cultivated? What species and varieties, and what modes of cultivation are best adapted for the production of Quinine yielding barks? Also what species are desirable for pharmaceutical use?

4. What is Resorcin, and what can you mention as to its uses and properties?

CHEMISTRY.

Time: 2 *to* 5 *p.m.*

1. What is the weight of 150 c.c. of the vapour of chloroform at 80° C. and 720 mm. pressure?

2. Give the formulæ and briefly describe the properties and methods of preparation of the following:—Phenol, Croton Chloral (so-called), Picric Acid, Salicylic Acid, Thymol, Ethyl Bromide, Apomorphia.

3. What is fermentation? Describe any varieties with which you may be acquainted.

4. Describe the action of an aqueous solution of hydrofluoric acid upon glass. Describe and illustrate, with equations, a process for obtaining pure silica from flint.

5. Describe briefly processes for the isolation of the following metals:—Aluminium, Magnesium, Silver, Lead, Potassium, Mercury and Calcium. Mention any evidence which can be brought forward to prove the existence of Ammonium.

6. What is the meaning of the following terms:—Homologous series, Isomerism, Allotropy, Isomorphism, Dimorphism, Actinism, Atomicity? Illustrate your meaning by examples.

The Jacob Bell Memorial Scholarships.

Mr. Taylor, being next called upon to report upon the competition for the Bell Scholarships, said that four years ago when this duty first devolved upon him he had expressed some regret that only 11 candidates competed. The following year the numbers rose considerably; in 1881 there were 18; in 1882 there were 20; and this year he was glad to say there were 25. He believed this satisfactory increase was due to the very pertinent remarks made last year by his colleague, Mr. Plowman, himself an old Bell scholar. He need not enlarge on the value of the scholarships, and he trusted that the number of competitors would be at least maintained in coming years. The examination had been conducted by Mr. Ekin and himself, and though they had no difficulty in selecting the two best men, he must say a word of encouragement to the two who came next, whose mottoes were "Aude sapere" and "Spero," who had done so well that he hoped they were young enough to try again.

The names of the successful candidates are—

Fraser McDiarmid
and
Robert Wynn Charles Pierce.

The questions that were set for this examination were as follows:—

Time allowed: *Two hours* (4 *to* 6).

CHEMISTRY AND PHARMACY.

1. Show by an equation what the result is of the action of diluted Nitric Acid on Copper.

2. What are the characteristics in common of the group of elements known as the Halogens, and whence the term Halogen?

3. How are White Precipitate and Red Precipitate prepared?

4. In what state does the Iron exist in freshly prepared Mist. Ferri Co., and what change, if any, occurs on keeping?

5. How much Oxygen and Hydrogen by weight and measure are required to form water, and what is the measure of the resulting vapour?

BOTANY.

1. Give the characteristics of any Natural Order with which you are well acquainted.

2. In what does a Dicotyledonous vary from a Monocotyledonous stem?

Time allowed: *Three hours* (12 *to* 3).
In awarding marks the neatness and legibility of the writing will be taken into account.

LATIN.

1. Translate in English:—

"Hoc erat, alma parens, quòd me per tela, per ignes,
Eripis? ut mediis hostem in penetralibus, utque
Ascaniumque, patremque meum, juxtàque Creüsam,
Alterum in alterius mactatos sanguine cernam?
Arma, viri, ferte arma: vocat lux ultima victos.
Reddite me Danais; sinite instaurata revisam
Prœlia. Nunquam omnes hodie moriemur inulti."

2. Parse *eripis, mactatos, reddite, sinite.*

3. Give the present infinite and supine of *emico, excutio, repeto, requiro.*

4. Translate into Latin:—

"Water being added it crumbles to powder."

ENGLISH.

1. Write a short essay on London, or any City of importance.

2. Parse the following lines:—

"He who fights and runs away
Will live to fight another day."

3. Give examples of Transitive and Intransitive verbs.

ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

1. What are the standards of weight and capacity in England, and how are they fixed?

2. Explain the "metrical system" of weights and measures.

3. Reduce 2 weeks, 5 days, 7 hours, 27 minutes to the fraction of a day; and $2\frac{1}{2}$ cwt. to the fraction of 2 tons, 12 lbs.

4. Add $5\frac{1}{2}$ cwt. to 3·125 qrs.; and reduce the sum to the decimal of a ton.

FRENCH OR GERMAN.

The candidate is at liberty to choose either French or German, and is not required to show a knowledge of both. Marks will only be awarded for one.

FRENCH.

Translate into English:—

"Si je garde quelque empire sur ma destinée, je ne serai jamais à Paris qu'un oiseau de passage. Cette vie tumultueuse, cette distraction sans trêve, ces gens toujours debout, toujours en l'air, toujours gais, toujours fous, me font entendre aux oreilles un bruit de grelots qui m'étourdit et me gêne. Je cherche mon pauvre moi et je ne le trouve plus. Quand je suis arrivée, j'ai cru tomber dans un carnaval dont j'attendais toujours la fin, mais inutilement, car il ne finit point, et c'est ici le fonds même de sa vie. Tous ces gens vont, viennent, s'agitent, s'empressent, se moquent et meurent tout à coup. La mort à Paris m'étonne toujours; elle ne m'y parait pas naturelle. Tout est si factice à l'entour que ce détail y choque comme un accident dans une fête. C'est la seule loi réelle de la vie qu'on n'y puisse oublier, parce qu'elle s'impose. Il me semble qu'on y méconnaît toutes les autres. L'accessoire, le luxe, l'ornement, la broderie, sont le principal et le tout. On vit de gâteaux, et point de pain." (Octave Feuillet.)

GERMAN.

Translate into English:—

"Verona die alte weltverühmte Stadt, gelegen auf beiden Seiten der Etsch, war immer gleichsam die erste Station für die germanischen Wandervölker, die ihre kalte nordische Wälder verlieszen, und über die Alpen stiegen, um sich im goldnen Sonnenschein des lieblichen Italiens zu erlustigen. Einige zogen weiter hinab, Anderen gefiel es schon gut genug am Orte selbst, und sie machten es sich heimatlich bequem und zogen seidne Hausgewänder an, und ergingen sich friedlich unter Blumen und Cypressen, bis neue Ankömmlinge, die noch ihre frischen Eisenkleider anhatten, aus dem Norden kamen und sie verdrängten,—eine Geschichte die sich oft wiederholte, und von den Historikern die Völkerwanderung genannt wird. Wandelt man jezt durch das Weichbild Verona's so findet man überall die abenteuerlichen Spuren jen' Tage, so wie auch die Spuren der älteren und späteren Zeiten." (Heine.)

The Inaugural Sessional Address.

The President having distributed these prizes, an Address was delivered by Michael Foster, M.A., M.D., LL.D., F.R.S., Professor of Physiology in the University of Cambridge. The Address is printed at the commencement of the present number. At its conclusion,

Sir Frederick Abel, in proposing a vote of thanks to Professor Foster, said there could be no one in the assembly who had listened with greater interest or pleasure to the words of wisdom which he had uttered. Although he (Sir F. Abel) had not that vast experience as an examiner which Professor Foster might claim, he had had a large experience years ago as an examiner. The unfortunate victims who came before him were of a different class altogether from those he now addressed, or to whom Professor Foster had referred. It had been his painful duty to examine youths on entering the military schools, to examine them while passing through the schools, on leaving, again when as officers they re-entered the schools, and when they again passed out, and again to submit them to the same process when passing to a higher grade in the service; and from his experience he could re-echo all that had been said as to examinations and as to many of the evils which attended them. One point struck him very forcibly, viz., that the teacher was the best possible judge of the powers and capacities of those studying under him. Nevertheless, in the wisdom which guided one large branch of the service it was held desirable not to appeal to the men who should best know the qualifications of those who had been educated there, and it was considered better to submit those men to the torture of unbiassed examiners, as they were called, who were accustomed by long practice to put the questions which men should answer in the form in which they were least likely to answer them. Consequently, in many cases the unready man, whom the teacher would put forward as the best man of his class, came out at the bottom. It was true that much of this evil was guarded against by the zealous efforts of the teachers themselves. He believed in examinations, and when years ago he was a teacher, he used to endeavour to follow in the steps of one of his great masters, Faraday, whom he had the honour of succeeding at Woolwich, and who used so to interlard his lectures with questions that the lecture might almost be considered an examination. And he did it in such a pleasant manner as never to discourage even the most backward. He remembered his asking on one occasion, "Mr. So-and-So, what will happen when I plunge this taper into this bottle of oxygen?" The youth scratched his head and said, "It will go out, sir." "*Not precisely,*" said Faraday, as if the answer was almost correct. The characteristic of a true teacher was that he not merely demonstrated a fact, but continually sounded his pupils to see what knowledge they had acquired.

Professor H. A. Armstrong, F.R.S., seconded the motion, and desired to thank Professor Foster for the important essay on examinations which he had given them. As a teacher and an examiner, although with but short experience as yet, he could vouch for the truth of what had been said. With reference to the course of study carried on in that institution and elsewhere he should like to remark that what was required in his opinion in all such schools was not so much that a man should gain a more or less superficial knowledge—as it must be from the time they could devote to the work—of several subjects, but that a few subjects should be so well studied that the power of carrying on study afterwards might be acquired. All who had been a few years out of their student's course knew that what they had learned since was very great indeed, as compared with what they learned during their student's career. It was the habit of work which was the most valuable thing learned.

The resolution was carried with acclamation, and briefly acknowledged by Professor Foster.

Presentation of the Hanbury Medal.

The President said the next part of the programme was of a different character from the first, which had been more or less connected with the work of students and examinations. He now had to perform, in conformity with a trust which devolved on the Council of the Pharmaceutical Society, another duty of a very agreeable character, that of handing over one of the greatest honours which could possibly be offered in the domain of the particular branch of science included in the trust to a gentleman who was selected *without examination.* Before, however, handing over the Hanbury Medal, it would be necessary to state the circumstances under which it was founded. Mr. Daniel Hanbury, a distinguished member of the Society, and at the time of his death in 1875 probably one of the greatest, if not the greatest pharmacologist in the world, died at a comparatively early age, far too early for the work he might have accomplished. He had done so much work for the advancement of pure science, especially that of pharmacology, that it was thought only fit and proper that some memorial of him should be established in connection with pharmacy. Accordingly, a limited subscription was suggested and immediately responded to; the result was, that shortly after his death, a fund was raised, and the influential Committee that had charge of it, decided that the best way of perpetuating Daniel Hanbury's memory would be to award a gold medal biennially for high excellence in the prosecution of original research in the chemical and natural history of drugs. There was no limit as to country or place. It was a medal open to all the world. A trust-deed was drawn to meet the resolutions of the Committee and the Pharmaceutical Society was made the trustee. It was also decided that the adjudicators of the Medal should be the Presidents for the time being of the Linnean, Chemical and Pharmaceutical Societies, the President of the British Pharmaceutical Conference, and one pharmaceutical chemist, who should, prior to each award, be appointed by the Presidents of the Pharmaceutical Society and Conference. The first award was made to a distinguished German, who was Daniel Hanbury's coadjutor and friend, being the joint author with him of one of the works by which he was best known, the 'Pharmacographia,' viz., Professor Flückiger. This year the judges, having taken the matter into consideration and considered the claims of American, European, British and Irish competitors for the Medal, came to the conclusion that the person of all others deserving the award on this occasion was an Englishman,

MR. JOHN ELIOT HOWARD.

He held in his hand the official award, which he need not read, signed by Sir John Lubbock, Dr. Perkin, Dr. Attfield, Henry B. Brady and himself. He regretted that owing in the one case to domestic affliction, and in the others to accidental circumstances, Sir John Lubbock, Dr. Perkin and Mr. Brady were not able to be present, but they desired him to express to Mr. Howard their extreme regret at not being able to assist at this award. It would ill become him to attempt to enumerate Mr. Howard's qualifications, but he might just say that his scientific work had been very largely, almost exclusively, in the chemistry and natural history of one single bark, the cinchona bark, the importance of which everyone present thoroughly recognized. He had before him three volumes with which Mr. Howard was more or less identified, and in one of them there were illustrations and a description of no less than forty-two species of cinchona. These, with many others, had been studied by Mr. Howard for many years at an enormous expense, for the benefit not only of those who were interested in pharmacology, but all mankind. For having regard to the value of the barks themselves, and the alkaloid quinine, it would have been impossible for the Government of India, and private growers of bark in Ceylon, to have carried on their operations with satisfaction and certainty if they had not been assisted from first to last by Mr. Howard, and the skill he had brought to bear upon the whole subject. Without saying more he would ask Mr. Howard to receive this medal and offer him most cordially not only his own respectful congratulations, but those of every pharmacologist in the world.

Mr. J. E. Howard said words would fail him to express the deep gratification which he experienced in receiving this proof of the appreciation of those for whose judgment he had so great respect. With regard to whatever he might have done in the way of scientific labour, he must say he considered himself still a student, and though he was happy to say he had not been subjected to an examination, he was a member of that Society. He was particularly gratified at receiving this medal, because it reminded him of the great assistance and sympathy he had received from the illustrious man in whose honour it was founded. His own love for science had sprung up spontaneously, and he followed it, not with any expectation of reward, but simply from the pleasure it afforded him. But he was induced and helped forward to publish the results of his observations more by Mr. Hanbury than any one else, and it was therefore to him very specially and exclusively that in looking back he might say he owed whatever advantage might have accrued to himself or others—from the publication of his researches. At that late hour he ought not to detain the meeting longer, though he should have liked to say a few words for the encouragement of his fellow students. He trusted they would all find the same interest that he had found in the study of the works of the Great Creator, and that they would all feel that which he would particularly seek to impress upon them, that there was no real contradiction between Christianity and Science. For himself he considered it the highest honour to be a Christian.

W. Johnstone.—(1) *Rhamnus catharticus*. (2) *Clematis Vitalba*. (3) *Artemesia vulgaris*. (4) *Odontites rubra*.

R. S. P.—Section xv. of the Pharmacy Act, 1868, enacts that "any person who shall take, use, or exhibit the name or title 'pharmaceutical chemist,' 'pharmaceutist,' or pharmacist,' shall be liable to pay a penalty of £5.

E. V. Z.—In all English colonies where Pharmacy Acts are in force, we believe without exception, the Minor qualification is accepted as entitling to registration without further examination. In the United States this is not generally the case.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Wednesday, October 3.

Present—Mr. J. Williams, President, in the chair; Professor Attfield, Messrs. S. R. Atkins, Borland, Hills, Naylor, Radley, Schacht, Taylor and Young; Mr. Ekin (Treasurer), and Mr. Plowman (Hon. Secretary).

The minutes of the previous meeting was read and confirmed.

Letters of apology for non-attendance were read from Messrs. Benger, Payne and Stephenson.

With regard to the distribution of the presidential addresses, delivered by Professor Attfield at the Southampton and Southport meetings, it was moved by Mr Schacht, seconded by Mr. W. Hills, and carried:—"That in accordance with the generally expressed wish of the general meeting of the Conference at Southport, it is desirable that the two addresses delivered by the late President, Professor Attfield, F.R.S., be distributed to members of both Houses of Parliament."

Professor Attfield presented the Conference with a sufficient number of copies of his first address for this resolution to be carried out. It was further resolved that the cost of printing, enclosing the two addresses in a cover, and adding any press notices, etc., be defrayed by the Conference. Professor Attfield was requested to distribute the copies either direct or, as far as possible, through gentlemen personally acquainted with members of Parliament.*

A Sub-Committee, consisting of the President, Professor Attfield and the Honorary Secretaries was appointed to arrange details.

Professor Attfield announced that he had already received applications from thirty individual chemists and druggists and two local associations for parcels of the Southport address, with added press notices. Twenty of these requests were for parcels of fifty, eight for packages of one hundred, one for two hundred copies, one for two hundred and fifty, one for five hundred, and one request for one thousand copies. The Committee agreed that the type of the 'Year-Book' should be used for such reprints, allowed the extension of the pamphlet from twenty-eight to thirty-two pages for the addition of press notices, and authorized the printers, Messrs. Butler and Tanner, Frome, Somerset, to supply the parcels requested and any others for which they might receive applications from chemists and druggists at the following rates, carriage paid:—Fifty for 4*s.* 6*d.*; one hundred for 7*s.* 6*d.*; five hundred for 32*s.*; one thousand for £3. Applications to be made to Messrs. Butler and Tanner as soon as possible.

The following gentlemen having signified their willingness to act as Honorary Colonial Secretaries for the undermentioned districts were unanimously appointed:—

Mr. H. Shillinglaw, Melbourne, for Victoria; Mr. L. B. Bush, Bathurst, for New South Wales; Mr. T. M. Wilkinson, Dunedin, for New Zealand; Mr. A. Walsh Port Elizabeth, for the Cape; Mr. H. S. Evans, F.C.S., Montreal, for Canada; and Mr. D. S. Kemp, Bombay, for Bombay.

The President and Honorary Secretaries were empowered to add to this list, before the next meeting of the Committee, the names of any gentlemen who had already been communicated with and who might announce their willingness to give their services to the Conference.

* Any pharmacist willing to assist in thus approaching members of Parliament should write for copies to Professor Attfield, 17, Bloomsbury Square, as early as possible.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. MacMunn, Messrs. Benger, Quinlan, Umney, Symons Haydon, Stanford, Wood, Baker, Quina, J. A. H.

REPORT ON THE STRENGTH OF COMMERCIAL SPECIMENS OF "SPIRITUS ÆTHERIS NITROSI," ETC.

BY W. H. SYMONS, F.C.S.,
Pharmaceutical Chemist.

Having had my attention drawn afresh to the variability of commercial spirits of nitrous ether, I determined to secure several specimens with a view to their examination. Application was made to various houses, and all, except one, furnished me with samples. The following table shows the results obtained by processes which I found gave constant results.

For determining the amount which separated when the spirit was "agitated with twice its volume of saturated solution of chloride of calcium," a 75 c.c. pipette was closed at its point by fusion, and the adjoining tube graduated: the tube at the other end of the bulb was cut off, at about 2 c.m. beyond the 75 c.c. mark, and fitted with a cork. Fifty cubic centimetres of saturated solution of chloride of calcium were then introduced, and the pipette surrounded by ice and water. In a few minutes the spirit to be tested was carefully poured in, so as not to disturb the solution. The cork being replaced, the pipette was well shaken, and afterwards allowed to remain in the cold water (with the graduated tube uppermost) for one hour. The amount of ethereal liquid which rose, multiplied by four, gave the required percentage.

In estimating the total nitrites the process described by Professor J. F. Eykman (*Pharm. Journ.*, [3], vol. xiii., p. 63) was used. The formula for calculation of results being $\frac{V}{S \times a} \cdot \frac{H-e}{273+t} \cdot 0{\cdot}1207 =$ percentage of ethyl nitrite. V represents c.c. of NO, H the barometric pressure, e the tension of aqueous vapour, S the sp. gr. of the spirit, a the number of c.c. used for assay, and t the temperature. The constant $0{\cdot}12071 = \left(\frac{100 \times 273 \times 75 \times {\cdot}08961}{760 \times 1000 \times 2}\right)$.

Samples.	Specific Gravity.		Prepared according to Pharmacopœia.	When shaken with two vols. sol. $CaCl_2$ there separates.	Result of Analysis upon 5 c.c. (by Eykman's process).	Per centage of Ethyl Nitrite.

The quantities of nitric oxide, and therefore of ethyl nitrite, in the table are in each case the mean of two or more experiments. The samples were, with the following five exceptions, obtained direct from London wholesale druggists. Nos. 2 and 14 I distilled myself according to the directions of the British and London Pharmacopœias respectively. From the house that supplied me with No. 1, as a sample, Nos. 9 and 10 were indirectly obtained; the latter having been purchased previously, the former afterwards. No. 21 was a 10 per cent. (by volume) solution in spirit (sp. gr. 0·834) of the ethereal liquid which rises on applying the B.P. test. The result indicates that this substance contains about 35 per cent. of ethyl nitrite. Its variability is, however, shown by Nos. 4 and 5: No. 5, probably containing more paraldehyde, threw up a trace, whereas No. 4, richer in ethyl nitrite, did not. No. 4 was purchased last May; it did not then separate anything with solution of chloride of calcium; it has been kept in a capped ether bottle and contains no more free acid than the other specimens, which are new.

From the above it will be seen that this preparation is far from what it should be. I am led to suppose that the manufacturers have not taken proper care in condensing the distillates by means of ice. It should be remembered that ethyl nitrite boils under 17° C., at normal pressure, and is therefore easily lost.

Where it is not possible or convenient to carry out Eykman's process, the Pharmacopœia sulphate of iron test (with weighed quantities) is quite capable of showing which is the better of two preparations. It may be applied as follows:—1 part of ferrous sulphate is dissolved in 5 parts of dilute sulphuric acid (B.P.), and to separate portions of 10 parts of this solution 1 part of the spirit to be tested is added. The dark-coloured mixtures may be then placed in glass vessels of equal diameter, and diluted with water until their tints, viewed horizontally, are similar. The amount of dilution shows the comparative strength. Attempts were made to obtain absolute quantitative results, using a standard solution of nitrite of potassium for comparison, and the usual process for colorimetric tests, but the results obtained were invariably too low; probably because the nitrite of potassium solution responds more thoroughly to this test, at the ordinary temperature, than does nitrite of ethyl.

MUSK.*

Musk is a secretion of the musk deer (*Moschus moschiferus*), which inhabits the Alpine regions of the northern provinces of Thibet, and is also found in the southern borders of China, and in Siberia as far as lake Baikal. According to recent reports, it has been found in the provinces of Fohkien and Kiangsi, but does not seem to be hunted there. The pouch that grows on the belly is about 2½ inches long, 1⅝ in diameter, and weighs about 30 grams (over an ounce). It must be cut off as soon as the animal is dead, tied up and dried. On the interior walls of this pouch is the musk, which looks like snuff, and which, if unadulterated, consists of smooth, dry particles, having a greasy feeling, is very friable, of a reddish-brown colour, and has the peculiar and unmistakable odour.

There are two principal varieties, Tonquin and Yunnan musk. The former comes from Thibet and Szechuen, the latter from the province of Yunnan, and both kinds find their way to Shanghai, through Chunking and Laukow. In addition to the ordinary Tonquin and Yunnan, there is a finer grade of each, distinguished by adding the term Taupi, thus Tonquin-taupi, which signifies the musk without the skin, otherwise the pouch is included. Both grades have an extremely fine perfume and bring a much higher price, but find little use in Europe. The odour is perceptibly different from the common ware, hence it might be supposed that they were derived from a totally different animal or came from another region.

A third sort is the Cabardine, or Russian musk, from Tientsin. Its perfume is not nearly so fine as that from Tonquin and Yunnan, and the loss from hair, skin, and moisture is much greater, hence its value is much less. Tonquin musk is the one chiefly exported to Europe and America. Cabardine musk is less esteemed there, and Japan is the principal market for the Yunnan musk. In the first half of 1882, Japan took 340 catties of this musk.

For some time past there has been a marked decrease in the quantity of Tonquin musk received. The Chinese dealers attribute this to the establishment of a protective law as to the hunting season. This circumstance, combined with active demand in London, and a small supply on hand, caused the price to rise from 71 or 72 taels per catty in 1881, to 120 taels in 1882. (The Shanghai tael is 1·15 dollar, and the catty weighs 1⅓ lb. avoid.) This hunting law is said to have been removed recently, but no change in price nor increase in receipts has yet been detected.

If some limit was actually put upon the musk hunting in Szechuen and Thibet, at all events Yunnan did not follow the example, for the receipts from this province are always abundant, so that the total export of musk seems but little less than last year. Independently from the fact that the price of Yunnan musk has followed that of Tonquin musk, the large production of the former had little influence upon the business in Europe, where neither sort has increased in favour or in consumption. The Chinese firms that deal in musk have, as a rule, branch houses in the chief cities of Yunnan and Szechuen, and in Chungking, Zchang, and Laukow. They advance the money to the hunters upon the musk, and thus prevent the article from falling into other hands than those of regular dealers. Every large musk firm has agents in Shanghai and Canton to look after the sales. In Shanghai, there are only five "hongs" for Yunnan and Tonquin musk; they all live in the same neighbourhood, and there is no competition between them, as they form a kind of monopoly. The business in other articles of export is done by brokers or middle-men, who are foreigners, and who carry samples of newly received products around to their customers; but with musk this is not the case. Here the buyers must seek some other means of informing themselves when a new "chop" comes in, and the musk dealers seek to secure themselves from being too quickly deprived of their wares. Musk is sold here only in the original chests of 10 to 20 catties (averaging 20 pouches), or in whole "chops." The buyer does not have his choice of the individual bags, cannot divide a chop, but must either take the original consignment just as it comes from the interior, or refuse it all.

There is no particular season for musk; it comes into the market at irregular intervals throughout the entire year. The Cabardine musk, brought from Tientsin, is sold by special "hongs."

The export of this drug will always remain within moderate limits, not only because the production is limited by nature, but also because the Occidental demand has as competitor the still stronger demand for home consumption. It is well known that in China everything smells of musk. Both sexes are accustomed to carry it with them in little boxes, and to keep it in their clothes presses. While it is losing ground in European therapeutics, the cures attributed to it in China are very manifold, as may be supposed from their mythical nature. When we consider that an export of 3000 catties, each catty containing 15 to 20 pouches of Yunnan, or 20 to 30 of Tonquin musk, means the sacrifice of no less than 60,000 musk deer, and this quantity has been reached several times of late years, and then if we add to this the consumption in China itself, which can scarcely be estimated, we see that it is not too much to fear the entire extirpation of this useful as well as graceful animal. Hence, it would be desirable that the before-mentioned rumour of the legal establishment of a period of protection should be confirmed, even if the development of this branch of trade should suffer somewhat in the immediate future.

The adulterations of this ware seem to be as ancient as the trade itself. Du Halde mentions it as being very common, and refers to pulverized rotten wood as one of the ingredients, and he also speaks of artificial pouches with which they avoided the law then in force against selling musk to foreigners. At present, really pure musk scarcely comes in the market at all. Even the best chops do not contain more than 50 or 60 per cent. of genuine substance, and on the average we must be satisfied with about 30 per cent. The adulterants of musk are generally coagulated blood, a fatty earth (or ochre), paper, hair, pieces of leather, etc., which are introduced into the bags so skilfully as to require a sharp eye and years of experience to be able to detect it. It is not customary here to make any chemical test. The musk inspector takes out a little of the substance with a silver needle, notices its odour, and estimates its value. The pods or bags are immediately assorted according to the percentage of adulteration that he thinks he has discovered in it, and put in piles called 1, 2 and 3, for the European or American market, where this classification is frequently changed and others substituted.

Each pouch is then wrapped in Chinese paper and put in a pasteboard box, lined with lead and covered with silk. Each of these boxes contains a catty of musk; they are finally put in a wooden box lined with zinc. These boxes are of different sizes, according to the sizes of the chop to be packed.

They are generally shipped by the mail steamers, being placed in the safe reserved for bullion and treasure. These precautions are necesary on account of the high price of the goods as well as liability to evaporation. The ships of the old East India Company are not allowed to take any musk on board.

The total export for the late five years was 25,664 catties, or 33,876 lbs., valued at 2,728,800 dollars. The chief port of export is Tientsin. Shanghai and Canton export very little.

THE APPLICATION OF ARBITRARY STANDARDS TO NATURAL PRODUCTS.

IN the earlier days following the first legislation respecting the adulteration of food in this country, among the substances which gave occasion most frequently for legal proceedings, milk was prominent and developed an extraordinary amount of conflicting "scientific" evidence, based upon the varying opinion of different individuals as to its composition when genuine. The researches of Mr. WANKLYN had, so far as they went, pointed to the comparative constancy in the proportion of "solids not fat" present in all milk, however the milk might vary in quality, provided that it had not been tampered with by the addition of any extraneous substance, and he had suggested that the proportion of 9·3 per cent. of "solids not fat" should be adopted as a standard representing the minimum quantity that should be present in milk. This standard was, however, disputed on many occasions as being excessively high, and subsequently the Society of Public Analysts resolved to adopt 9 per cent., as representing the minimum proportion of "solids not fat" that should entitle a sample of milk to be reported upon as unwatered. Although, however, this standard has been very generally accepted and acted upon, it has not escaped an occasional protest, and a decision in the Manchester City Sessions Court on Saturday last will considerably weaken its authority.

The case which then came under consideration was one on appeal in which a Derbyshire farmer had been convicted on a charge of having adulterated milk supplied by him to a retailer by the addition of 4 per cent. of water. The report of Mr. ESTCOURT, the public analyst, upon which the charge was based, was to the effect that a sample of milk obtained from the defendant contained only 8·67 per cent. of non-fatty solids, which led to the conclusion that it contained at least 4 per cent. of added water. The defendant, however, denied the correctness of the conclusion and a portion of the sample having been sent to Somerset House for examination, the official chemical authorities there—Messrs. BELL, BANNISTER and LEWIN—reported that while unable to affirm that the milk had not been adulterated they had found the constituent parts of this sample to be in the same proportion as had been observed in genuine milk, and that they did not consider it could be affirmed with certainty that water had been added. Mr. ESTCOURT's opinion was, however, supported by three other analysts, and the magistrates being in a difficulty, applied a numerical process in the weighing of evidence, and on the ground that four analysts said the milk was adulterated and three that they would not affirm that it was pure, convicted the defendant. It was an appeal against this conviction that was heard on Saturday last by the Recorder of Manchester. In the opening of the appeal it was contended by the counsel on one side that the standard of 9 per cent. of non-fatty solids was one that was in accord with the results of experiment and had the approval of many chemists, and on the other, that by the 22nd section of the Sale of Food and Drugs Act, the justices were bound to act upon the report from Somerset House and ought to have dismissed the case. This latter view of the case, however, the Recorder refused to adopt. A large number of scientific witnesses were examined on each side, but it may be stated generally that Mr. ESTCOURT's analytical results were not disputed, for although there was a disposition to pit them against the results obtained at Somerset House and to object to the latter on the ground that the milk when examined there had undergone decomposition, Dr. BELL disposed of this objection by saying that after making a slight addition, the amount of which was based upon experiment, the results arrived at by Mr. ESTCOURT were practically the same as those obtained in the laboratory at Somerset House. The question was therefore narrowed to whether any deficiency from 9 per cent. of "solids not fat" should be considered as proof—warranting a criminal conviction—that a corresponding quantity of water had been added. In support of an affirmative to this question, evidence was given by Messrs. ESTCOURT, WANKLYN, DUPRÉ, WIGNER and BLYTH; whilst negative opinions were expressed by Messrs. BELL, VOELCKER, THOMPSON and BANNISTER. Dr. BELL admitted that the average amount of non-fatty solids in fresh milk is 9 per cent., but said he had found it to vary between 8 and 10 per cent. or even higher, and once he had received a sample from Chester in which the amount was below 8 per cent. Dr. VOELCKER, whose wide experience enables him to speak with some authority, said that he had met with milk containing as low as 7½ per cent. and many with less than 9 per cent. Amongst the instances quoted by him was the milk from the cows which last year competed, as milk-givers, for prizes given by the British Dairy Farmers' Association. Out of twenty-six of these samples nine were found to contain less than 9 per cent. of "solids not fat." Dr. VOELCKER is of opinion that the standard adopted by the Society of Public Analysts is in reality too low, because it does not require a fair proportion of fat, but he is not prepared to recommend any other standard. The Recorder, in delivering his judgment, pointed out that the proceeding was of the nature of a criminal prosecution and that before confirming the conviction he ought to be satisfied beyond all reasonable doubt that the defendant was guilty of the charge brought against him. But he said that the conclusion to which he had come was that the charge had not been so made out and that he ought therefore to allow the appeal and dismiss the original conviction with costs.

As already remarked, this decision will undoubtedly considerably diminish the importance which has hitherto attached to the standard adopted by the Society of Public Analysts, but not unreasonably so. Unless we are to dismiss reiterated testimony that milk from individual cows—or even the collected yield from herds of cows—is met with containing in its natural unsophisticated condition less than 9 per cent. of non-fatty solids, it must be obvious that such a condition observed in any milk is not, by itself, a proof that water has been added sufficient to warrant a conviction for a criminal offence. It may be that such milk is abnormal; that such a condition is even a sufficient indication that it is unfit for human consumption. But that is not an offence under the Act; neither is it an offence that a cow fails to produce milk equal to a standard which in the opinion of any number of men, however competent, represents what milk ought to be. It may be desirable that there should be a standard of quality in milk fixed, and that the sale of milk that does not attain to it should be made illegal; but that would be the duty of the Legislature and cannot be allowed to be assumed by private individuals or associations of experts. This tendency to set up arbitrary and unofficial standards has been manifest in other respects than towards the article of milk; but whilst content that such standards as have been set up by the Legislature shall be enforced strictly, we protest against the idea that they may be strained to accomplish ends for which they were not enacted, or that others may be set up by irresponsible persons to meet imaginary wants, even with the best intentions.

PROFESSOR HUXLEY ON STATE INTERVENTION IN MEDICAL AFFAIRS.

On the occasion of the delivery of prizes to successful students at the London Hospital on Tuesday last, Professor Huxley delivered an address on the intervention of the State in the affairs of the medical profession, in which he raised the questions as to the grounds upon which State intervention is justifiable, the extent to which it ought to go, and the manner in which it might be most profitably exercised. Replying to the first question, he said the ground of intervention was not the protection of the public against incompetence or quackery, since if such intervention were advisable it is not practicable, as it would be impossible to prevent people from buying drugs or seeking advice from whom they please. As to the extent to which State intervention should go, Professor Huxley would limit it to securing that no man shall die without the cause of his death being formally certified, making provision that the advice of recognized experts shall be available in civil and criminal trials, and guaranteeing the competence of persons appointed to the numerous medical offices at its disposal, and he maintains that at present the State keeps within these limits in this country. Although anybody may practise medicine, a broad practical distinction is drawn between "qualified" and "unqualified" practitioners, and the Professor considers that practically the latter are very heavily handicapped. Even if the enforcement of penalties against those who profess to be qualified when they are not were somewhat swifter and sharper, he does not think the present condition of affairs would be thereby improved. As to the last question, whether justifiable intervention, as defined, is at present carried into effect in the best possible manner, Professor Huxley says that the reply given by common consent is a very decided negative. Recognizing the vast improvement that has taken place since the passing of the Medical Act of 1858, he affirms that the evidence laid before the late Royal Commission showed that there are licensing bodies that tout for custom by a low standard of examination; that others grant licences which do not involve proof of an acquaintance with the three great branches of medical practice,—medicine, surgery and midwifery; and that the law in its present state does not enable the Medical Council to deal with these evils by enforcing an equality of minimum examination and the threefold qualification before admitting a medical practitioner to registration. But the "conjoint scheme" upon which the Medical Bill recently before Parliament was based, Professor Huxley describes as a highly complex and cumbrous machinery, wholly untried and of doubtful efficacy, for the purpose of superseding Universities and corporations that are at present doing their work exceedingly well. He considers that the end in view might be attained easily and without the least interference with any of the existing bodies that have acquired a high status by doing their duty, by the addition of two simple clauses to the existing Act: one providing that no person shall be admitted to registration who fails to produce evidence that he possesses a knowledge of medicine, surgery and midwifery; and a second, providing that such evidence shall consist in the certificate of any examining body, a certain number of the members of which are appointed as coadjutors by the Medical Council. Upon the subject of medical education Professor Huxley was equally explicit and expressed an opinion that considering the many subjects now included in the curriculum the student might with advantage commence his scientific studies two years earlier.

At a meeting of the Evening Meetings Committee, on Wednesday last, it was decided that in order to afford greater facilities for the examination of specimens and apparatus exhibited in connection with the evening meetings during the present session, the doors of the Lecture Theatre shall be opened an hour before the taking of the chair at each meeting (*i.e.*, at half-past seven o'clock) and that the Curator of the Society's Museum should be requested to be in attendance to give information concerning the articles exhibited. Members and other persons wishing to exhibit objects of interest should communicate with the Curator at as early a date as possible.

We are requested by Professor Bentley to state that in addition to the students in the Botany and Materia Medica Class of last session who were awarded medals and certificates, Mr. William Johnston obtained in the examination a sufficient number of marks to have entitled him to a certificate had he been a student connected with the Pharmaceutical Society.

As the time appears possibly to be coming within measurable distance when attendance at definite courses of instruction in recognized schools will become an indispensable preliminary to the compulsory examination as to qualification for registration as a chemist and druggist, it is satisfactory to learn that arrangements are being made that will make such instruction available in different parts of the country. At the Inaugural Meeting of the new session at Owens College, Manchester, on the 2nd instant, in a report presented by the Dean of the Medical Department, it was stated that two newly constructed laboratories and a spacious museum in the new buildings just opened have been devoted to the department of materia medica and pharmacy, and that it is the intention of the Professor of Materia Medica to organize forthwith practical classes to be conducted, under his superintendence, by the Demonstrator, Mr. W. Ellborne, who was lately Assistant-Curator of the Pharmaceutical Society's Museum, which shall embrace courses of instruction specially arranged to meet the wants of students of pharmacy residing in the district. Professor Gamgee added that he believed the new arrangements would develop in the College to an extent not previously possible the teaching both of materia medica and botany, and would enable students to learn thoroughly the fundamental operations of pharmacy and the distinguishing characters of drugs.

In Sheffield the initiative has been taken by the Council of the local Pharmaceutical and Chemical Association, which has made arrangements with the authorities of Firth College for the establishment of courses of lectures and laboratory practice that will meet the requirements if the proposed curriculum should come into force. During the coming session, commencing on Tuesday next, there will be a course of twenty lectures each, on Physics (Wednesdays, 7.30 p.m.); Chemistry: Non-Metallic Elements (Fridays, 7 p.m.); and Inorganic Chemistry: Metals (Tuesdays, 7 p.m.). It is intended that a course of twenty lectures on Organic Chemistry shall be delivered next session, which would complete the curriculum requirement of eighty lectures on Chemistry, including Physics. It is also hoped that lectures on Botany and Materia Medica may be arranged for during the summar months. The Laboratory will be open for practical work daily and on two evenings in the week. Any further information could no doubt be obtained from the Honorary Secretary of the Sheffield Pharmaceutical and Chemical Association, Mr. Newsholme, Market Place, Sheffield.

In a recent communication to the Royal Microscopic Society, the veteran pharmacist, Mr. Peter Squire, described a process for preserving in a satisfactory form specimens of the beautiful fresh-water medusa (*Limnocodium Sowerbii*), the occurrence of which in the Victoria Regia tank at the Royal Botanic Gardens has created so much interest amongst naturalists. It consists in plunging the animals, removed by means of a glass-tube used as a pipette, into a dilute solution of mercuric chloride (2 to 4 grains to the pint of distilled water), previously raised to a temperature of 85° F., which is that at which the animals live. Through the consequent coagulation of albumen the bodies of the animals which during life are nearly transparent become opalescent and the minutest details become apparent. It may interest some of our readers to know that a specimen prepared by Mr. Squire is in the possession of the Curator of the Society's Museum, and may be seen upon application.

Arrangements are being already made by some pharmaceutical bodies in anticipation of the meeting of the International Pharmaceutical Congress, in Brussels, which, according to the terms of the resolution passed by the Congress in London, should be held next year. The appointment of delegates from the American Pharmaceutical Association has been referred to the Executive, and from a statement on another page, it appears that a similar nomination to represent the Pharmaceutical Society of Ireland has been completed. Meanwhile no report has reached us that any steps are being taken by those upon whom it devolves to organize such a meeting.

One of the subjects that occupied the attention of the Austrian Pharmaceutical Society at its last general meeting was the necessity for a new Austrian Pharmacopœia, the present one having been issued in 1869, and since then only supplemented by a very insufficient appendix.

We have great pleasure in stating that Professor Attfield has been elected an Honorary Member of the Denmark Pharmaceutical Association.

The Inaugural Meeting of the sixth session of the Edinburgh Chemists' Association will be held on Wednesday evening next, in the rooms of the Pharmaceutical Society, 119A, George Street, Edinburgh, when an address will be delivered by the President, Mr. C. F. Henry. A Syllabus of the Session, extending to April, 1884, has been prepared.

We regret to have to record the death of Mrs. Annie Collins, on the 17th of September, at the age of sixty-seven years. Mrs. Collins was elected a Benevolent Fund Annuitant in 1876, and is the seventh annuitant who has died since the election in December last.

Pharmaceutical Society of Ireland.

ANNUAL GENERAL MEETING.

The Annual General Meeting of this Society was held on the afternoon of Monday, October 1, at four o'clock, at its new rooms, 11, Harcourt Street, Dublin.

The chair was taken by the outgoing President, Professor Tichborne.

The first business was the ballot for the election of the Council for 1883-4. Messrs. Wells, Batt and Edmondson were appointed Scrutineers.

The President, in briefly addressing the meeting, said the members were aware that the Society had now completed its twelfth year of existence, and he thought he might say that during that period it had been fairly prosperous. They all recollected the great impulse the interests of the Society received in the first instance from its being taken up by the late Sir Dominic Corrigan; they should never forget all that they owed to his name and position and the great interest he took in the Society. When his health broke down he resigned his position as President of the Society, and he (Professor Tichborne) was selected in his place. During the time he had been in office,—and he might be allowed to refer to it as that was his last appearance before them as President,—he had endeavoured as far as he could to keep up the high position in which Sir Dominic Corrigan had left the Society. If he had erred in anything it had certainly not been from any want in that respect. On his motion a resolution had been carried at a meeting of the Council requiring that the Society should elect a new President every three years, the object being to secure an infusion of new blood into the office, and to prevent the operation of those feelings of delicacy which might otherwise restrain the members from changing their President. A triennial period had been decided on, but it might be found desirable hereafter to have an annual election. At present, however, he did not think the Society was large enough to warrant them in having a new President every year. They were making another new departure also this year. He that day welcomed them to their own house. Their new premises were not yet complete, but they were well furnished and presented a very fair appearance; and the thanks of the Society were due to the Committee to whom had been entrusted the task of carrying out the arrangements. As he had already said he thought they were entitled to come to the conclusion that the Society was fairly prosperous. It was true that only fourteen pharmaceutical chemists had passed their final examination during the last twelve months; but during that period thirty-seven had passed their Preliminary examination, which added to the previous number made three hundred and twelve in all. Besides, the Preliminary examinations of other licensing bodies were accepted. The Society consisted of between sixty and seventy members,—he wished there were more,—and there had been enrolled over two hundred licentiates, so that there was no doubt that the body of pharmaceutical chemists after a little time would become a power in Ireland. Prosecutions had been carried on and were going on at the present time, and he was glad to say that the Society was in a more wholesome condition as regarded these matters than before, for it had now a guarantee fund to defray the expense of prosecutions, which was a proof that the Society intended to maintain its position and to prevent illegal compounding in the country. If prosecutions could be carried out at a minimum of expense or at no expense to the Society it would be a most desirable state of things. The intention of the Act of Parliament was that the Society should be at no expense for prosecutions, and should even clear a couple of pounds on each, but in the practical working of the matter it turned out that each prosecution cost from £25 to £30. There had been considerable talk of late about the status of the pharmacien and it was maintained that he was more than a mere tradesman, and in fact a professional man. He thought they would all agree to that. But it was necessary to produce an impression on the public mind to that effect. That was one of the objects he had always had in view as President, and he thought that the Society should endeavour to follow it up. Unless the pharmaceutical chemist proved to the public that he was a better man than the co-operative store man he would not be able to compete with the latter. He (the President) would not detain them any longer, but would ask the Treasurer to read his report as to the financial condition of the Society.

Mr. Hodgson, Treasurer of the Society, said he was sorry there was not a larger attendance on that occasion; and he particularly regretted the absence of the Vice-President. The balance in the Bank of Ireland was £62 0*s.* 10*d.*, as compared with £17 15*s.* 11*d.* at the corresponding date last year. The income from examinations had been £212 2*s.*, as against £190 last year. Then subscriptions from members last year amounted to £68 5*s.* for sixty-five members; in the year just expired they had only received £53 11*s.* from fifty-one members. Other items brought the income for the past year up to £290 14*s.* 4*d.* The expenditure included £50 8*s.* to the examiners; £13 13*s.* for the reporting of the meetings; fees to Mr. Purcell, Q.C., for an opinion, £2 2*s.*; minor expenses of Law Committee, 17*s.* 10*d.*; salary to Mr. Fennell, £52; remuneration to porter, £9; rent up to May 1, £40; and printing and stationery, £16 14*s.* 6*d.* There was also the item of £34 14*s.* 4*d.* for the *Pharmaceutical Journal.* The total expenditure had been £228 13*s.* 6*d.*, which left a balance of £62 0*s.* 10*d.* The accounts had been vouched by Dr. Collins and Mr. Hayes. He (Mr. Hodgson) had to thank the Society for entrusting the duties of Treasurer to him. He was sorry that the funds were not larger, and he was convinced that the greatest economy would be required for a considerable period in order to keep the accounts in a satisfactory state.

Mr. Grindley: Is there any other outstanding debt?

Mr. Fennell said there was a printing account which had not been furnished.

Mr. Hodgson: There will be a very considerable sum due against the next meeting for the furnishing of these rooms, but it does not come into the present account, and will be paid out of capital.

Mr. Wells said that taking into account the unfurnished account for printing, the amount of which he understood from Mr. Fennell to be between £20 and £30, and also what would be the liability for rent, the Society was not much more than solvent.

On the motion of Mr. Brunker, seconded by Mr. Simpson, the Treasurer's account was received.

The Scrutineers of the ballot submitted their report, from which it appeared that forty-nine voting papers had been sent in and that the following gentlemen were elected to the vacancies on the Council:—Dr. Tichborne, 47 votes; Mr. Allen, 45; Mr. Grindley, 44; Mr. Hayes, 0; Mr. Doran, 38; Mr. Evans, L.A.H., 37; and Mr. Draper, 35.

The President moved that Mr. J. E. Brunker, M.A., be elected President of the Society for the next three years. That gentleman's merits were so well known that it was unnecessary to dilate upon them. As a pharmacian he was a representative man, having one of the most important establishments in the city, and he had worked indefatigably to maintain the interests of the Society.

Sir George Owens said he had not known of this proposal before, but he had great pleasure in seconding it, for he was sure that Mr. Brunker would make an excellent President.

The motion was put and unanimously agreed to.

The newly-elected President (Mr. Brunker), having taken the chair, thanked the members for the distinguished honour they had conferred on him. He promised them that as far as his exertions went they should be given towards maintaining the Society at as high a standard as possible and promoting the rapid advances which pure pharmacy was making both in that and the sister country. The honour they had been good enough to confer on him was quite unsought. Having regard to the present position of the Society he did not look on the office of President as an easy one, and he trusted that he should receive a large measure of support from the Council and the Society generally. The old maxim *Ex nihilo nihil fit* was quite applicable to the present position of the Society; it could not be worked without the sinews of war, and he trusted that an increased number of the licentiates would become subscribing members.

Dr. Montgomery moved a vote of thanks to the Society's late President, Professor Tichborne, for the very laborious and extremely courteous manner in which he had attended to the duties of the office since the death of Sir Dominic Corrigan. The members would fail very much in their duty if they did not pass a marked vote of thanks to him. At all times his services had been perfectly available for the Society; and it had been a great acquisition to it to have a scientific man like Professor Tichborne at its head. He trusted, however, that though he had ceased to be President himself, Professor Tichborne would afford to the newly-elected President the benefit of the great experience he had acquired during the number of years that he had presided over the Society.

Mr. Hodgson said that having been anticipated in moving this motion it gave him great pleasure to second it. Professor Tichborne's scientific knowledge and well-established name had given a *prestige* to the Society.

The President said he was sure the motion would be carried by acclamation. To Professor Tichborne was due the getting up of the evening meetings, which were of so much importance to the younger members of the Society.

Professor Tichborne briefly thanked the Society for the vote which had been passed, and for the complimentary remarks which had been made in reference to him.

Mr. Grindley moved that Mr. J. C. Payne, of Belfast, be elected Vice-President. Mr. Payne had thoroughly identified himself with the interests of the Society and would always support its *prestige*; he (Mr. Grindley) thought the honour which he now proposed to confer on him was due to the North of Ireland.

Mr. Wells said he had very much pleasure in seconding the nomination of Mr. Payne. He quite agreed with Mr. Grindley that the honour of the Vice-Presidentship was due to the North of Ireland.
